Guy Elliott Mitchell of the United States Geological Survey, in an article in the *National Geographic Magazine* for February, 1918, stated that the total production of petroleum in the United States up to 1918 was 4,255,000,000 bbl. In regard to future production, he estimates that the total amount in the ground, some of which lies very deep, is about 7,000,000,000 bbl. This is small compared with the quantity of oil that can be extracted from our oil-shale deposits. He tells us that American deposits of oil shale will supply enormous quantities of oil in the future. It is estimated that 20,000,000,000 bbl. can be obtained from the oil shale in Colorado alone; that certain ranges of mountains in which these deposits are located carry thick beds of rock that yield 30 to 100 gal. to the ton. The shale deposits of Indiana are estimated to carry 100,000,000,000 bbl. of oil. There are also deposits in Wyoming, Nevada, Illinois, Kentucky, Ohio, Pennsylvania, Tennessee and West Virginia; therefore our oil supply for the future is assured, even though we fail to develop additional oil territory other than the shale deposits.

Victor J. Azbe.[1] Fuel oil is the ideal fuel for boiler purposes. It gives high boiler efficiency, high boiler capacity, rapid regulation, low cost of handling, low cost of firing with hardly any disadvantages, but it should not be burned in localities with a coal mine only 30 miles off. In the southern states, especially Texas, plants are equipping to burn lignite in preference to the present expensive fuel oil, and those which are not should be made to do so.

Lignite is the best fuel to be burned in territory where available. Very good results can be obtained with it and 12 per cent CO_2 maintained without difficulty. With intelligent firemen in charge as high boiler efficiency will be obtained with lignite as with coal and it has not been unusual for the writer to obtain 65 per cent combined efficiency with ordinary return tubular hand-fired boilers; and with proper design boilers can be forced far beyond rating with lignite.

The value of wood as fuel also is not realized, and as an example I will mention a certain plant in Louisiana that burned oil for years at 80 cents per barrel. All at once the cost of oil increased to $1.40 and they began burning wood and during the next fiscal year the cost of fuel per unit of output was far less than with oil at 80 cents. To think of this and then of the enormous quantities of wood wasted throughout Mississippi and Louisiana and other states makes a man realize how unadaptable we are.

H. A. Barre.[2] Oil is practically the only fuel used for power purposes in California, except for a small amount of natural gas.

Originally it was burned as it came from the wells, but of recent years the crude oil is all topped for the lighter constituents, and the residual only, having a gravity of 14 deg. to 18 deg. B. used for boiler fuel. The unit of measurement is the barrel of 42 gal. weighing about 335 lb. and containing

[1] General Manager, Municipal Lighting Department, Pasadena, Cal.

[1] Junior Mem.Am.Soc.M.E.; Engineering Dept., Anheuser-Busch Brewing Asso., St. Louis, Mo.

[2] Southern California Edison Co., Los Angeles, Cal., Mem.Am.Soc.M.E.

from 6,000,000 to 6,200,000 B.t.u. Compared with 12,000-B.t.u. coal, one ton of 2000 lb. equals nearly four barrels of oil.

Before the war the price for favorable delivery points, such as tidewater and pipe-line terminals, was 60 to 70 cents, equal to \$2.40 to \$2.80 coal. At present the market is about \$1.45 per barrel, equivalent to \$5.80 coal per short ton.

These figures are not entirely just as a comparison, since the expense to store and fire oil is much less than for the corresponding thermal equivalent of coal. There are no ashes to dispose of, and ease of control in firing admits of higher operating plant efficiencies. The same amount of investment will therefore produce higher thermal efficiencies than with coal.

Two large and comparatively modern plants have been for some years under the writer's observation. One of these is of 40,000 kw. capacity, having three 5000-kw. engine-type units, installed in 1906, which are seldom used, and two 15,000-kva. turbines installed in 1910 and 1911. The other is of 47,000 kw. capacity, having one 12,000-kw., one 15,000-kw., and one 20,000-kw. turbine. This is much the better plant.

These two plants are a part of a large interconnected system having a total capacity of nearly 200,000 kw., and run in conjunction with a number of water-power plants.

They serve three functions—(1) As a steam reserve for breakdown of lines and other plants; (2) To supply kilowatt-hours during the season of low water; (3) To care for increases in load until these reach sufficient magnitude to justify bringing in additional water power.

The annual loads and load factors are, therefore, of an erratic nature.

The operating conditions for several years past are shown in Table 5.

TABLE 5 OPERATING CONDITIONS WITH FUEL OIL

	40,000 KW.			47,000 KW.		
Year.	Kilowatt-Hours Output.	Bbl. of Fuel Oil.	Kilowatt-Hours Per Bbl.	Kilowatt-Hours Output.	Bbl. of Fuel Oil.	Kilowatt-Hours Per Bbl.
1911....	126,377,000	574,178	220.03	....	.....	....
1912....	150,801,000	732,444	206.00	50,300,000	240,537	209.0
1913....	163,015,000	756,652	215.44	94,046,000	439,454	214.0
1914....	18,588,000	161,190	115.30	74,812,000	347,008	215.7
1915....	5,274,000	88,576	59.50	77,556,000	328,749	236.0
1916....	3,785,000	81,783	46.30	45,360,000	218,235	207.5
1917....	4,930,000	83,692	58.80	133,528,000	562,177	238.0

It will be seen that the best annual operating results have been approximately as shown in Table 6.

In both these tables the results are net after accounting for station auxiliaries; that is, the measurements are oil delivered to the stations and kilowatt-hours output at the station feeders.

TABLE 6 BEST OPERATING RESULTS

Plant	Kilowatt-Hours per Bbl.	B.t.u. per Kilowatt Hour	Per Cent Efficiency
40,000 Kw.	220	27,300	12.5
47,000 Kw.	240	25,000	13.67

Some oil-burning plants having a high load factor have recently been put into operation in Arizona, operating at about 19,000 B.t.u. per kw-hr., or nearly 18 per cent efficiency.

In these two plants a 600-hp. B. & W. or Sterling boiler will carry with auxiliaries about 1000 to 1100 kw. of station output.

The arrangement of the furnace is more important than the type of burner used.

The oil is usually atomized by steam. The resultant spray is burned by mixing with the proper quantity of air also distributed evenly throughout the firebox without directly striking the surfaces of the tubes and furnace walls, but also without permitting the occurrence of blank spaces which might admit a surplus of air.

There are several types of burners, between which there is little to choose. Any of them that will properly atomize the oil and distribute the flame are satisfactory. The two extremes of the scale of desirability are, on the one hand, the burner which, by the use of a slight excess of atomizing steam, gives steady and reliable service, and, on the other hand, the one where the steam passages are reduced to just the amount necessary for atomization, but which must be watched a trifle more carefully on account of plugging up at times with dirt or carbonized oil.

The steam consumption of the former type is not over 4 per cent of the boiler output, and of the latter slightly less.

The most important instrument for oil burning is a window in the roof, through which the boiler-room engineer can see the top of the stack. Smoke, of course, is always a loss, and when firing up cold boilers cannot be avoided. A more serious loss, however, is excess of air, and this can occur with a perfectly clear stack. The best firing will be done by increasing the amount of air until the smoke stops and then cutting it down slowly until a slight haze of smoke shows.

In the larger plants, of course, more scientific methods are available. Steam-flow meters, venturi meters on unit groups of boilers, and the customary stack instruments are used and pay better returns than perhaps any other part of the investment, provided always that the information obtained from them is used for the immediate correction of any deviation from normal conditions.

3 How Can Soft Coal Be Burned Without Smoke in Marine Boilers?

The avoidance of smoke would decrease the radius of visibility of our ocean carriers by many miles and greatly reduce their liability to attack by submarines. If efficiency is improved incidentally it means much more than the mere coal saving.

Albert A. Cary. It has been repeatedly asked how to avoid the production of smoke from the steam-generating equipments of transatlantic vessels under the present conditions of submarine menace. It is an extremely vital question which has seemed to evade its answer most adroitly. After having studied this matter carefully for some time, in the light of almost 30 years' experience with most of the special furnaces and smoke-suppressing devices in this country, and many of those abroad, I can state without qualification that this trouble *can* be met, practically and satisfactorily, provided our marine friends are willing to meet us half way in their new constructions and make a compromise between old, time-honored marine-boiler practice and successful land practice.

Although an innovation, this does not mean drastic changes from their present form of steam-generating equipment; it simply means getting sufficiently away from the furnace practice long followed which has caused the submarine-signaling smoke nuisance.

The question submitted in this topical discussion is very simple and direct, and equally direct answers might be given.

by stating: suppress the fires in the furnace by firing in such small quantities as to prevent the emission of smoke; or, secure *complete* combustion in the furnaces and combustion chambers. The first-named method, of course, must result in a serious loss of the vessel's speed. The second method gives the only wholly rational solution of the trouble.

The average types of marine boilers with their present form of attached furnaces make it well-nigh impossible to secure complete combustion within the furnace in such a way as to suppress smoke without sacrificing efficiency. On the other hand, it is possible to make rational changes in the steam-generating equipments for *new* ships so as not only to suppress the smoke nuisance, but to carry vessels through the danger zone at their highest speed.

To accomplish this highly desirable end by working along the lines of the latest successful developments in land practice, we shall probably require 4 ft. more headroom, in which to place the boilers, but even should 5 ft. be demanded, the tremendous advantage gained would far offset any objections that could be raised to this innovation in the marine-boiler practice of the past.

EXAMPLE OF A STATIONARY INSTALLATION APPLICABLE TO MARINE PRACTICE

To illustrate, I will refer to an equipment for stationary boilers in which I have been interested from a purely professional standpoint, and which can be practically adapted to marine service in new vessels to secure high rates of coal consumption without producing smoke.

Eighteen stokers have been operating 500-hp. boilers 24 hours per day continuously for two years, at 50 per cent above their rating, with average grades of eastern bituminous coal of no better quality than is used by transatlantic ships. They have been continuously burning from 42 to 45 lb. of coal per sq. ft. of grate per hour, with a clean smokeless chimney and have shown an easy forcing capacity when over 60 lb. of this eastern bituminous coal is burned per hour per sq. ft. of grate.

The coal is fed from the hopper to the fuel bed in a steady flow in such manner as to avoid the trouble usually following its coke formation and the troublesome caking, and then it is moved along the grate automatically so as to constantly drop its ash directly down to the grate surface where the cool entering air keeps the temperature of the ash below its fusing point, thereby avoiding the formation of obstructing clinker.

The resulting ash is dumped into an ash-sealed pit where it is water cooled and an automatic ash-removing device carries it forward into the front ashpit without disturbing the ash seal and without disturbing the draft conditions of the furnace.

The deep fuel bed is always kept in an open porous condition over its entire surface like a huge sponge, thus requiring a light air-blast pressure, seldom exceeding 1-in. water pressure and allowing each stoker to be operated with an individual disk fan (requiring but little power to operate) instead of the usual heavy steel-plate, forced blast fan with its voluminous air ducts. The result is not only a saving in power required for operation but also a material saving in space requirements.

With the clinkering trouble in firebed, side and bridge walls thus avoided, hand cleaning of the firebed is almost entirely done away with while the firebed is easily kept level and of uniform thickness by an arrangement of the automatic-feed device.

Adjustment of the rate of coal feed is quickly and easily changed (along with the speed of the fan) and thus, with the free-burning firebed conditions existing, a jump from low to high steaming capacity in the boiler is obtained in a very few minutes.

With such exceptional fuel-burning conditions under marine boilers, the production of smoke would be prevented by securing practically complete combustion in the furnace, and the highest steaming capacity of the boiler obtained to take the vessels through the danger zone at high speed.

With the coal supplied to the furnace by simple conveying apparatus and with ash delivered from the ashpit automatically by the stoker and conveyed overboard automatically, hand manipulation can be almost entirely done away with and a happy solution secured of the present difficulty in getting the greatly needed expert firemen.

OSBORN MONNETT.[1] As to whether soft coal can be burned without smoke in marine boilers, there can be but one answer: Yes. As a purely engineering problem it is feasible. Of the methods tried for this work the underfeed principle has been best adapted. With this method the headroom and ashpit facilities may be cut to a minimum and the auxiliary machinery required is comparable to that ordinarily used for forced draft hand-fired furnaces. Furthermore, this principle of burning soft coal is well adapted to the character of the load (variable speed, etc.) and handles to good advantage the class of coal customarily used for marine purposes on our eastern seaboard. Theoretically, all points are in its favor.

Moreover, considerable practical experience has been gained with underfeed stokers in marine work in the past ten years. A number of marine installations are operating successfully today, among which might be mentioned the following: steamer *Sprague*—6 Scotch marine boilers—12 stokers; tug *Perfection*—1 marine firebox boiler—1 stoker; tug *Mollie Spencer*—1 marine firebox boiler—1 stoker; dredge *Wm. O'Connell*—2 double-end Scotch marines—8 stokers; steamer *Gamma*—6 tubular boilers—6 stokers; dredge *Hecla*—2 Scotch marine boilers—2 stokers; Ward Engineering Co. steamers—2 Ward marine water boilers—4 stokers; Holland-America Line steamer, *Frederick VIII*—8 Yarrow boilers—16 stokers.

These installations, all of the Jones underfeed type, cover a wide variation of marine service from dredges and river steamers to transatlantic liners, and all types of boilers, including Scotch marine, marine firebox and water-tube boilers, of both straight- and bent-tube varieties.

The problem is not so much a mechanical one as it is one of the human element. Put one man (fourth engineer) who is familiar with this type of equipment on duty on each watch and no difficulty need be experienced. The necessary men could be recruited from the large number of power plants in this country now using underfeeds.

As far as hand firing with Scotch marine boilers is concerned, experience has been discouraging. The writer once succeeded in operating smokelessly a steamer so equipped, without any apparatus, simply by changing alternate fires. It happened that the boilers, two in number, were equipped each with three corrugated furnaces, all discharging into a common combustion chamber. The volatile matter from the fresh fire was consumed by the hot gases from the other two fires. With two furnaces the results would have been less satisfactory, and with separate combustion chambers (a common construction) impossible.

The idea in hand-fired furnaces has been to mix the gases, after they pass the bridge wall and while they are at a high temperature, with an auxiliary supply of air, and so accomplish complete combustion. Experiments have been made in

[1] American Radiator Company, Chicago.

Chicago harbor with brick arches, baffles and other constructions calculated to do this, but the small space available in the Scotch marine boiler has prevented satisfactory results. In fact, the writer's experience with forced draft, induced draft, special air admission, preheated air, panel doors, steam jets, induction tubes, stack blowers, hollow bridge walls, etc., etc., has led to the conclusion, more strongly than ever, that some type of underfeed stoker is the logical answer to the Scotch marine boiler problem.

In water-tube boiler construction, such as has been adopted by the Emergency Fleet Corporation, there is more opportunity to do things and it is not unreasonable to hope that a satisfactory hand-fired furnace for these units will be developed.

H. B. Oatley.[1] At or above the normal rate of operation, the burning of soft coal with the complete elimination of smoke, if not impossible, is an extremely difficult problem. A great deal, however, can be done to approach this desired state of perfection.

Conditions which will secure proper combustion may, of course, be provided on new ships and we are led to expect well-designed boilers, furnaces and uptakes on the ships now building. On existing vessels, however, unfavorable conditions may exist with respect to the proportions of air openings through the grates, volume of furnaces and combustion chambers, area for gases through fire tubes and around water tubes, and finally areas of uptake, breeching and stacks. The means for heating the air supply, in forced-draft installations, may have been inadequately proportioned. It is very desirable—in fact it is imperative—to improve these conditions to the greatest extent possible. It is probable that to correct these conditions, so far as the boiler itself is concerned, would be prohibitive on account of delay and expense in installing new boilers. Grates, uptakes and the air-admission channels, however, may be corrected in a short time and at a reasonable cost.

The personnel in the fireroom is a prime factor in the success or failure of any boiler plant. It must be realized that the rapid expansion of our shipping requires recruiting of men with little or no experience in the fireroom. Great effort and expense are justified in giving all possible training to the fireroom crews.

Steam economy is a big factor in the elimination of smoke, because it results in reduction in the amount of fuel used and reduction in the rate of combustion.

Improvement in marine steam plants, considering the present use of triple-expansion engines, turbines, feedwater heaters, well-lagged steam pipes, etc., presents fewer opportunities than in other lines. In the use of superheated steam, however, marine power plants in this country are considerably behind the merchant marine in other leading countries. There are opportunities for reducing the fuel used by upward of 12 per cent, and naturally a *greater* percentage reduction in the smoke produced. This is particularly applicable to existing ships as the necessary installations may be made at moderate cost during an overhauling. A reduction in the fuel used would make suitable many plants that have restricted areas through which the gases pass, and permit of greatly improved combustion.

For existing ships there is a greater reduction in smoke to be expected by the more economical use of steam, at least under present conditions, than by any other means.

M. C. M. Hatch.[2] Soft coal can be burned without smoke in marine, as in all other boilers and furnaces, up to the point at which the furnace volume becomes too small to allow for proper air-mixing and combustion space for the volatile hydrocarbons contained in the coal. This varies, of course, with designs, but the limits imposed by the unavoidable restrictions in designs for marine work make it most difficult to force high ratings from such boilers, under hand-fired conditions, without smoke.

The earlier in the combustion process that intimate mixture of air and volatile gases occurs and the smaller the volume of excess air necessary to complete combustion and hold down furnace temperature to workable limits, the greater is the amount of coal that can be fired (and consumed) per unit of time per unit of furnace volume without smoke, and hence the higher the rating which the boiler can deliver.

Coal, in pulverized form, induces the desirable intimate mixture of gases and air very early in the process of combustion and it has been shown, as it is logical to expect from the very nature of its burning, that less total air is needed per unit weight of fuel, than with hand firing. In support of this it has been repeatedly shown, in locomotive and stationary practice, that smoky coals can be burned smokelessly at very much higher rates of combustion than possible under any other conditions. The logic of the case and the facts in other services all point to the conclusion that soft coal, in pulverized form, can be burned in marine-boiler furnaces at much higher rates than will ever be possible to attain with hand firing, and that smoke will be eliminated or very materially reduced. To just what point the furnaces could be forced, in any individual instance, depends, very largely, on their fundamental design and volume, but in any case the smoke thrown would certainly be much reduced by the use of pulverized coal.

Henry Kreisinger. Perhaps the best way of burning soft coal in marine boilers without smoke is to do away with hand-fired furnaces and install mechanical stokers or pulverized coal.

For smokeless combustion, two requirements are essential: first, the volatile matter must be distilled at a uniform rate; second, the distillation must take place in the presence of large amounts of free oxygen so that the volatile matter can be burned before the smoke is formed. These requirements are not satisfied in the hand-fired furnace. On the other hand, most of the mechanical stokers, as well as the powdered-coal furnaces, furnish means of satisfying these two requirements.

In the hand-fired furnace the distillation is rapid immediately after firing and most of the volatile matter is distilled during the first half of the firing cycle. It is difficult to supply enough air during this period of rapid distillation without having too high an excess of air after the distillation has been nearly completed, unless the air supply is varied in such a way that it is at all times nearly proportional to the amount of volatile matter that is being distilled. Such variation of air would require close attention on the part of the fireman and is hardly practicable aboard a ship where firemen are changed frequently.

In the hand-fired furnace the distillation of the volatile matter takes place in the absence of oxygen, and the volatile matter is broken down by heat into soot and light hydrocarbons. The fresh coal is placed on top of the fire and moves down towards the grate. The air is fed from below through the fuel bed in the opposite direction to that of the coal. Before the air reaches the distillation zone at the surface of the fire, all the oxygen is used up in burning the carbon in the lower

[1] Lieutenant, U. S. Naval Volunteers; Chief Engineer, Locomotive Superheater Co., New York. Mem.Am.Soc.M.E.

[2] Locomotive Pulverized Fuel Company, New York.

layers of the fuel bed. The sooty smoke is formed at the surface of the fuel bed because there is no oxygen to burn the volatile combustible, and because the latter is subjected to high temperature; it is not formed by sudden cooling.

Most mechanical stokers feed the coal into the furnace at a uniform rate so that the volatile matter is distilled also at a uniform rate. It is therefore comparatively easy to adjust a uniform supply of air to the volatile matter to insure its complete combustion without a too high excess of air.

Furthermore, with most of the mechanical stokers the air and the coal are fed into the furnace in the same direction, so that at the point where distillation takes place the air contains nearly 20 per cent oxygen. On account of this large percentage of free oxygen the combustion of the volatile matter proceeds to completion without deposition of soot.

What has been said about the mechanical stoker is true of the pulverized-coal burner. The coal and air are fed into the furnace together at a uniform rate so that the two can be easily adjusted to the proper proportion. The volatile matter is distilled from the small particles of coal while the latter are surrounded with an atmosphere containing nearly 20 per cent of oxygen.

With the pulverized coal a large part of the mixing of the combustible with the air can be done outside of the furnace. Thus the combustion space of the furnace needs to do only the burning and little mixing. Something similar to this is being done in the gasoline engine. Only the burning is done in the combustion chamber, the mixing being done in the carburetor. High temperature is of lesser importance. Complete combustion can be had in the gas-engine cylinder in spite of the fact that the walls of the combustion chamber are water-cooled.

Carrying on the mixing outside of the furnace deserves full consideration in the case of marine boilers, because the restriction of space on board ship makes large combustion chambers prohibitive.

HAYLETT O'NEILL (Oral). For the past two months I have been running tests of marine boilers using pulverized coal at New Haven, Conn. We have been able to burn this fuel without smoke, and have obtained just as much speed and power as with the regular oil-burning equipment aboard this ship. The boilers are of the Normand express type, with a very small furnace particularly unsuited to such fuel as powdered coal. I believe that the future will see much work done in marine practice in the way of substituting coal for oil, inasmuch as the fuel in the form of coal will cost about one-half or even one-third what the oil will cost.

[On board the boat mentioned by Mr. O'Neill a mixture of powdered coal and fuel oil is used—32 per cent of the mixture being coal, 95 per cent of which passes through a 200-mesh screen. The coal remains suspended for many days without settling so seriously as to interfere with operation. The usual mechanical Navy burner is used without alteration. The volumetric heat value of the mixture is about the same as that of the straight oil with an average good coal because of the greater density of the coal. If this mixture of oil and coal proves to be successful, it would, of course, if widely applied, go a long way toward relieving the consumption burden now imposed on our fuel-oil resources.—EDITOR.]

JOHN S. SCHUMAKER[2] (Oral). In the Assabet mills, Maynard, Mass., about twenty-one Manning type boilers were used to burn New River coal. The furnaces of these boilers have no firebrick, and, ordinarily, considerable smoke was formed in the combustion of the coal. It may be interesting to know that this trouble was practically eliminated by the introduction of air above the fire. The fire doors were at first left on the latch, that is, left open a trifle, and later, as a permanent arrangement, 5-in. openings were introduced in each door. These openings, when properly regulated, greatly reduced the smoke.

4 What Are the Possibilities in the Direction of the Utilization of Anthracite Wastes?

What success have you had in burning anthracite slack or culm? Do you mix it with soft coal and in what proportions? What sort of grate do you use and what is your practice with regard to thickness of fire, draft, rate of combustion? Can the mixture be burned in a stoker?

JOHN E. MUHLFELD.[1] The indications are that during the current coal year (April 1, 1918, to March 31, 1919), about 80,000,000 tons of anthracite coal will be mined for distribution as compared with 77,000,000 tons during the past year, of which latter amount about 5,500,000 tons were exported. Of this year's output probably 25,000,000 tons will be steam sizes, leaving 55,000,000 tons for domestic and specialized uses.

New England alone will require about 13,000,000 tons of anthracite, exclusive of steam sizes, whereas, according to the Anthracite Committee of the United States Fuel Administration, its allotment is now placed at about 10,500,000 tons.

The exclusion of almost one-half of the 18 states in the Union from participation in this year's anthracite-coal production, and a shortage of 25,000 to 50,000 men from the number normally engaged in the anthracite mining field, in combination with the lack of water and rail transportation facilities, establishes the immediate necessity for reclaiming and utilizing every ton of anthracite silt, slush and culm that is now being produced or which is stored above ground.

CONSUMPTION OF ANTHRACITE AT THE MINES

As about one ton of anthracite coal is now consumed at the mine in the production of steam to mine each 8 or 9 tons produced, the logical use to which these waste sizes should be put is in the production of power, heat and light at the mines. By this procedure useful by-products of from 11,000 to 12,000 B.t.u. heat value per pound—which are now being wasted by diversion to streams, back filling into abandoned mines, or by dumping in culm banks, and which represent about 10 per cent of the total tonnage mined—can be made to release from 85 to 90 per cent of the commercial-size anthracite that is now being consumed for mine steam generation for use in locomotives and at industrial plants located nearest the points of production. In other words, in the production of 80,000,000

[1] Pres., Locomotive Pulverized Fuel Co., New York. Mem. Am.Soc.M.E.

[1] Larchmont, N. Y.

[2] S. D. Warren & Co., Cumberland Mills, Me. Assoc.-Mem.Am.Soc. M.E.

tons of domestic and steam anthracite during the current coal year, the reclamation and utilization of the silt, slush and culm by-product for mine-operation purposes would release about 8,000,000 additional tons of steam-size anthracite that could be diverted to commercial use, and more than make up the shortage in supply.

It should be remembered that the only cost for this additional tonnage would be the means required for its reclamation and for its preparation and use, as the labor, material and plant for mining are now being employed in its production.

By pulverizing this by-product anthracite and burning it in suspension, as oil or gas is burned, it can be used for stationary-boiler purposes without the admixture of any other fuel, and easily produce from 100 to 150 per cent of the rated boiler capacity. For locomotives it can be utilized by mixing 60 per cent with 40 per cent of any gas or soft bituminous slack or screenings available, then pulverizing, and burning it in suspension.

Burning Anthracite in Suspension

The ideal means for preparing and disbursing this fuel would be to install preparation plants at the collieries, from which both locomotives and stationary power plants could be supplied, thereby relieving railway facilities, locomotives and cars otherwise required for its transportation. Such utilization would also avoid the use of cars and vessels for hauling fuel with a relatively high percentage of non-combustible. Every ton of anthracite to be shipped by rail or water for any considerable distance should have not more than 10 per cent of ash and impurities and be of the best quality possible to conserve the already overburdened transportation facilities.

Here are millions of tons of anthracite coal that average higher in heat value than the average run-of-mine bituminous coal in Michigan, Illinois, Iowa, Missouri, Kansas, Oklahoma, Texas and other points of the West from which about one-third of the bituminous coal supply is now being produced, and for which anthracite by-product, man and machine power, mining equipment and supplies are being used daily in its production, with the resultant waste of output for want of installation of proper means for its effective and economical utilization.

These by-products can be reclaimed and utilized for what it now costs to place them on the dump or to pump them back into the mines, and by proper preparation and burning in suspension—as with oil or gas—there will be the additional power-plant advantages of reduction of man power, greater boiler capacity, better control of steam pressure, elimination of banked fires, decreased ashpit handling, elimination of fire cleaning and of metal work in the furnace, better combustion, and lower fuel losses.

Furthermore, with the relatively low volatile nature of these waste by-products, which require a temperature of between 550 and 600 deg. fahr. to produce combustion, there will be no difficulty in handling or storing fuel after pulverized, in any manner desired from the standpoint of loss of heat value or spontaneous combustion.

At present the bituminous coal supply is only running at from 75 to 80 per cent of production, due largely to shortage of from 10 to 15 per cent in the car supply. As the anthracite supply of commercial steam sizes is also inadequate, unless some means is immediately adopted to provide for the reclamation and utilization of useful mining by-products, we can expect the same hardships on the people and the manufacturing industries as obtained last winter.

W. S. Hachita.[1] The anthracite industry is located in the northeastern part of the state of Pennsylvania. The area underlaid with anthracite is approximately 800 square miles. Roughly the field is divided into four parts: namely, the northern field, comprising the Carbondale, Scranton, Wilkes-Barre and Nanticoke districts; the northern middle field, or Hazleton district; the southern middle field, including Mahanoy City, Shenandoah, Mt. Carmel and Shamokin; and the southern field, consisting of Lansford, Pottsville and Tremont districts.

In preparing anthracite, there are two kinds of waste produced: first, fine material, the largest pieces of which are no bigger than 3/32 in., which is so fine that, heretofore, it has been considered unmarketable; second, rock refuse. The latter material has been picked out during the process of preparation. The production of culm at present is approximately $7\frac{1}{2}$ per cent of the total output.

Culm Production in Tons

The average culm production from the beginning of the industry to the present time (1820-1918) is about 15 per cent of the tonnage mined. According to the statistics, the anthracite mined and shipped from 1820 to January 1, 1918, amounts to 2,332,673,250 tons, so that the amount of culm produced during the same period is 349,901,000 tons. Out of this, about 50 per cent has been taken into the mines to support the roof and washed away, leaving 174,950,000 tons available above ground in the whole anthracite field.

The rock refuse, which consists of slate and bony coal, amounts to approximately 10 per cent of the output, or about 233,267,000 tons. The slate which occurs in anthracite measures is entirely unlike that used in roofs, sidewalks, etc. On the other hand, it contains from 28 to 48 per cent of combustible material, while the bony material contains from 45 to 70 per cent of combustible. The rock banks, composed of slate and bone, contain at least 50 per cent of the heat in commercial anthracite. At the present, rock refuse is not utilized as fuel in the anthracite field.

The fine material which is locally known as culm slush, or silt, contains 70 to 85 per cent of combustible material. It is therefore a good fuel, provided proper means of burning it can be used. During the last sixty years, a large amount of experimenting has been done with a view of utilizing this material.

A thorough research, relative to the utilization of anthracite culm was made by the Lehigh Valley Coal Co. in 1913, at the Spring Brook boiler plant, near Hazleton, Pa.

For this purpose there were arranged a battery of four cylindrical boilers, 33 in. in diameter and 30 ft. long; one smoke stack, 33 in. in diameter and 33 ft. high; a total grate area of 132 sq. ft., having air space of 19.8 sq. ft., or 15 per cent of the total area.

The fuel was burned under forced draft of ½-in. water gage. The mixture consisted of culm and bituminous coal. In the test, the fuel was fired in alternate layers of bituminous coal and culm, also a thorough mixture of both fuels in various proportions. It was soon found that a thorough mixture of culm with bituminous coal was the better method and this method was therefore used throughout the tests.

Mixtures of Soft Coal and Culm

The first series of tests consisted of 30, 50, and 70 per cent of run-of-mine coking coal mixed with 70, 50 and 30 per

[1] Lehigh Valley Coal Co.

cent of culm from the Hazleton Shaft Colliery of The Lehigh Valley Coal Co. The second set of tests consisted of a mixture containing pulverized bituminous coal. The biggest pieces of soft coal in the mixture were not larger than 2 in. in diameter. Both fuels were thoroughly mixed in the above proportions by the use of shovels, and fired. The result of these tests shows that, in every case, the pulverized bituminous coal produced the better results.

The non-coking bituminous coal was also tried but it did not produce the same results as those produced by the coking coal. The reason why the coking coal is better adapted to mix with the culm lies in the fact that the coking coal fuses at a comparatively low temperature and the fusion takes up the particles of culm, forming a homogeneous mass of fuel which burns uniformly. The results of these tests show that a mixture consisting of 30 per cent of culm and 70 per cent of coking bituminous coal produced a water evaporation equal to that evaporated by the straight bituminous coal. It was also noticed that the mixture was easier to burn than soft coal alone. This is due to the fact that when soft coal alone is burned, the fuel bed becomes a hard, coked mass requiring considerable poking to effect complete combustion, whereas in the case of the mixture, the coked fuel is more easily handled by the fireman. It was also noticed that the fuel produced little smoke.

In September, 1917, E. E. Loomis, president of the Lehigh Valley Railroad Co., was informed by F. M. Chase, vice-president and general manager of the same company, about the formula of the mixed fuel with the view of burning the mixture on stoker engines. It was then decided to try it on big freight locomotives running between Hazleton and Lehighton, a distance of 26 miles. In this test, the fuel consisted of 30 per cent culm and 70 per cent of stoker coal or slack. The train was made up of 50 cars of coal hauled from Hazleton to Lehighton and returned to Hazleton with 65 empty cars. There was no trouble experienced in the test and later evaporation tests made on locomotives using the mixed fuel and straight bituminous coal.

More Steam with Mixed Fuels

The results of these evaporation tests showed that the mixed fuel produced approximately 30 per cent more steam than straight bituminous coal although the calorific power of the latter was considerably greater than that of the mixed fuel. This is due to the fact that the complete combustion of the hydrocarbon is possible in the mixed fuel, whereas, in burning straight bituminous coal, the greater part of these valuable hydrocarbons are lost as smoke.

B. S. Murphy. Our plant was designed to use the small sizes of anthracite coals and under normal conditions we have no difficulty in doing so even with the No. 4 or dust. The increase in the impurities with a relative decrease in calorific value due to colliery methods, such as mining, failure to wash in the larger sizes, such as No. 1, the large amount of shale and pebbles in the so-called river coals, dredged coals, etc., has placed a different aspect on the problem; but one that can be solved successfully for such plants as are now equipped or will procure the necessary equipment.

The coal used varies from straight No. 1 buckwheat to No. 3 and No. 4, the latter, or dust, using the recommended A.S.M.E. scale, being that passing through a 3/32-in. opening. Our so-called No. 3 has from 45 to 60 per cent dust and the No. 4 over 60 per cent and up to 85 per cent through 3/32-in. screen.

Influence of Size of Coal

It is most desirable from both an economic and operating standpoint to adhere to one size of coal for as long time periods as possible. It is impossible to maintain good economy when the run of coal for the boilers changes continually from the smaller to the larger size and back again, for an entirely different method of manipulation is necessary. On the other hand, if the fuel is a well-mi ed one, say one as follows: 15 per cent of No. 1, 20 per cent of No. 2, 40 per cent of No. 3 and 25 per cent of No. 4, and remains as such, it can be handled well and in fact is easier to handle than the No. 3 for poor firemen.

The reason for the mixture of bituminous coal with the anthracite is twofold: (*a*) to act as a binder and (*b*) to increase the calorific value. With the large size, No. 1 buckwheat, our practice is to add no soft coal. Here we find that the soft coal is a detriment, forms clinker with the impurities and makes the firing more difficult.

With the small sizes the primary function with the good coals—11,500 B.t.u. to 12,000 B.t.u.—is to act as a binder to hold the fire on the grates, and with the poor coals to increase the calorific value as well.

The amount necessary to bind the fuel varies from 5 to 10 per cent, say 7.5 per cent as a mean; this again will depend, however, on the quantity of the No. 4 size. The smaller the coal particles the greater the amount of bituminous required, until with the straight No. 4, say 80 per cent, from 15 to 20 per cent should be used.

Another use for the bituminous coal is the "building of bottoms" in the fire and the repairing of holes. This is especially true with the untrained firemen, and our practice is to have a small bunker of bituminous on the fireroom level where the men can get a few scoopfuls from time to time for this purpose.

Bituminous Mixing

It is of the utmost importance to have the bituminous well mixed with the anthracite, for the better the mixture the less required and the better the economy. In small plants where the coal is brought to the fires in barrows it should be turned in on the floor similar to mixing concrete.

Our practice at the present is crude and consequently does not give the best results. The coal is delivered in bopper-bottom cars, a predetermined number of buckets of bituminous is added from a storage pile on top of the car, by means of a locomotive crane. The coal is then dumped on conveying belts delivering the mixture to a crusher and thence to the overhead bunkers. In the summer this method works fairly well, but in the winter, with the coal frozen, the soft coal may be delivered to the bunkers some 30 or 40 min. before the coal in the car is all unloaded, because the pockets thaw first and the soft coal goes through a long while before the ends of the car thaw enough to flow. This results in uneven distribution about the boilers, some chutes having far too much soft and others not enough. Here again the emergency bunkers on the fireroom level come into play.

An element that enters into hand firing of small anthracite sizes is the vast formation of soot or flue ashes. It is necessary to carry considerable draft and the result is that some of the combustion is similar to that of powdered fuel; it never reaches the grates after leaving the fireman's shovel, it either ignites and burns in the air or is brought over to the rear connections in the form of coke. The greater the rating, the larger the soot deposits due to the greater draft neces-

sary; but even working the boilers at light loads, a very large amount is formed. Our boilers were designed with this in view and have a large space in back of the bridge wall to allow this soot to accumulate, and soot pipes extending down into the ash cellar to allow it to run directly into the ash cars; our economizers are also equipped with soot pipes for this purpose. With the No. 4 coal and insufficient soft coal in the mixture, we will build up soot four or five tubes high between cleanings of soot hoppers, or in six hours.

To give an idea of the magnitude of this, we have had months when the weight of the soot removed was 10 per cent of the weight of the coal fired; this is exceptional, and it should be from 6 to 7 per cent. It may be of interest to note that at times an analysis of the soot shows a slightly higher calorific value than the coal it was made from, due to the fact that the soot is principally coked coal without impurities. We have attempted to burn this but with no success. However, if a small briquetting plant with a cheap binder were available, it could be done successfully. The soot formed by the stoker is naturally but a small percentage of that in the hand-fired boiler.

The gates are the inclined dumping type, with an area of 190 sq. ft. per boiler of 900 hp. The air spaces are 20 per cent with one and 9 per cent with the other.

Thickness of Fire

Our practice is to carry as thin a fire as possible without danger of blowing through and forming holes. The thickness of fire hinges on the formation of a good bottom after cleaning, say about 3 to 5 in. thick, and then building up as slowly as possible. We clean before the service hour and start cleaning again as soon as the peak is over, some two hours if the fires will stand that long. The thickness of the fires at the time of cleaning is problematic, depending on the load carried and the coal; we have had them from 20 to 24 in. or even heavier, but 16 to 18 in. will be nearly an average.

The amount of draft available is of the utmost importance as it is impossible to use the small sizes without a high ashpit pressure. At our Terminal Building in New York we can carry the normal load, somewhat below boiler rating, with natural draft, but here, on account of the great height of the stack, about 320 ft. above the top of the grate, we have an unusual condition: when the boilers are brought to rating the natural draft has to be augmented by blowers. At the Jersey City Power Station we use from 2½ to 3-in. water gage between loads and from 4 to 7 in. during the peaks, depending upon load and condition of fire.

The rate of combustion varies with the load and coal. During our peak hours, with poor coal we burn from 40 to 60 lb. per sq. ft. per grate per hr., while for the whole 24 hr. the rate will be from 20 to 25 lb.

We have but one stoker installed at the present, a Coxe (chain grate), but we are now equipping all of our hand-fired boilers with this type of stoker.

Handling Frozen Coal of Fine Grades

An important consideration in the use of culm for fuel is the thawing of coal during the winter months if the coal is delivered to the plant in cars. On account of its compactness the moisture freezes to a hardness equal to that of lean cinder concrete and a dull-point chisel is necessary to cut it. If a thawing house is not available, special provisions will have to be made. Our practice is to use from 8 to 12 thawing pipes per car, 1¼-in. extra heavy pipe fittings with cap and tee at upper end, a drive point at the lower end and the lower portion of the pipe above the drive point perforated with a large number of small holes. The pipes are entered in the top of the pile in the car and after the thawing begins are driven down from time to time with a wooden maul. The pipes connected in series are fed with 140-lb. superheated steam. It requires from two to six hours for this and then the car is brought over the unloading hopper. The car hopper will be iced so badly that it also will have to be thawed, especially the operating mechanism. To do this we use portable nozzles made up of three 1-in. pipes clamped together with a common steam connection to a rubber steam hose, the outlets of the pipes staggered to make an equilateral triangle and bent at right angles to the body of the pipe. This will thaw the car-door mechanism within a few minutes, so that the doors can then be opened. The worst frost will be found here on account of the drainage accumulation at the low parts, but about ten minutes with two nozzles will start the coal running in the worst car, opening a hole to the top of the car and allowing the coal thawed by the top pipes to run out. It must be borne in mind, however, that this will require a large amount of steam; we find this equivalent to 10 tons of coal per 24-hr. day for from 12 to 18 cars unloaded. It is also necessary to have quite a gang of men working in the car; we use from 4 to 8 to the car because considerable picking is necessary where the coal adheres to the metal sides of the car.

Storage of Anthracite Coal

We attempt to keep from 13,000 to 14,000 tons of small-size anthracite in storage at all times and find that there is no deterioration after at least two years' storage. The greater part of our coal is stored outdoors and this does not change at all. Some 2,600 tons have been stored for one year in overhead storage bunkers where the summer temperature becomes very high. When we had occasion to use it last winter, it had naturally become very dry and powdery and formed somewhat more soot than the new coal; otherwise it gave satisfaction.

W. G. Diman.[1] We have at the plant of the Amoskeag Manufacturing Company 185 Manning boilers of which 169 are running today; all boilers are fitted with Jones underfeed stokers. About two years ago we began to get small quantities of anthracite screenings and refuse; the amount has been increasing until we are now burning hard coal of No. 2, No. 3 and bird's-eye sizes straight under 135 boilers, and hard coal mixed with a small percentage of soft coal under the other boilers.

When we began to receive the hard coal we experimented with various mixtures, but finally used the fuel straight on each to get comparisons of the various grades to assist us in buying. We found that with the regular installation of the Jones stoker the coal was pushed over on to the dead plates and lay idle there with no chance for air to mix and consume the coal. When the buckwheat was hot, it acted like sand and the tuyere blocks on the side of the retorts had a tendency to blow the coal over to the side and pile it up. In order to make an even fire and to get better distribution of air for burning, we put in pin-hole dead plates with about 270 ¼-in. holes, or a total increased air area of about 14 in. The plates were not faced off but were rough castings, which allowed considerably more air to get into the fire. I think still better results would be obtained if we cut off some of the air spaces in the tuyere blocks and added air space in the dead plates. This would

[1] Supt. of Power, Amoskeag Mfg. Co., Manchester, N. H.

reduce the open spaces in the bed caused by the tuyeres' blowing away the coal and produce a more even fire. Some of the coal drops into the pits, which have to be cleaned out to prevent their burning and forming explosive gases.

We carry a light fire, about 6 in. to 8 in. thick, which allows the air to get through. About 2 in. water pressure is carried at the tuyere blocks and no draft in the uptake. We burn about 600 lb. of coal per hour or about 26 lb. of coal per sq. ft. of grate. The larger the grate and the easier the fire is run, the better the results.

We have had to run anthracite coal as high as 25 per cent in ash. When doing this we have considerable trouble with the fires and handling the ashes. We find that the more we handle the fires the greater the loss. We cannot get efficient results out of coal containing much more than 20 per cent ash and if we should get coal containing 40 per cent ash it would be useless to us. In view of the transportation problem and freight rates, the place to burn any coal having about 25 to 30 per cent ash is at the mines, where they can equip to burn the specific fuel which is produced.

The following notes show what results we obtained from our tests, all of which ran 12 hours. Each lot received is tested before and during shipment to see if its quality compares favorably with other coal of the same kind.

An average of 20 tests of straight soft coal of different qualities gave an efficiency of 76 per cent with an evaporation from and at 212 deg. per lb. of dry coal of 10.7 lb. The ash averaged 8 per cent. These tests were made without any perforations in the dead plates.

One test of mixture made with two-thirds soft coal and one-third buckwheat gave an efficiency of 74.7 per cent with an evaporation of 9.93 lb. from and at 212 deg. per lb. of dry coal; and the ash averaged 11.4 per cent. This gave a good fire but, of course, required a little more work and attention from the firemen. The load could be easily carried under these conditions.

An average of two tests of mixture made with one-half bank coal and one-half soft coal gave the following results: efficiency, 58.3 per cent, evaporation from and at 212 deg. per lb. of dry coal, 6.97 lb.; ash, 19.73 per cent. This coal was somewhat dirtier than the average and required considerable work from the firemen. We burned about 670 lb. of coal per hour and ran about 93 per cent of the boiler's rating. The results of all our tests with culm prove that it is much below buckwheat and smaller sizes in evaporation and the only way to get it on a basis with buckwheat is to increase the soft coal percentage, which of course increases the mixture price. It would take three parts soft to two parts culm to equal two parts buckwheat and one soft.

An average of two tests made with a mixture of two-thirds buckwheat and one-third soft coal gave an efficiency of 66.2 per cent with an evaporation of 7.96 lb. of water from and at 212 deg. per lb. of dry coal; ash, 14.83 per cent. These two tests were made on a little better grade of bank coal. We burned 676 lb. of coal per hour, and obtained 95.1 per cent of the builder's rating. The boilers are of 150 hp. each. We used a draft in the tuyere blocks of 1.59 in. and 0.07 in. in the uptake. When burning this mixture, the fire burns well but needs close attention. A light fire must be carried.

An average of eleven tests of anthracite refuse, which includes bank coal and culm (no soft coal used), gave the following results: efficiency 55.7 per cent, evaporation from and at 212 deg. per lb. of dry coal, 6.75 lb.; ash averaged 17.8 per cent. We consumed 628 lb of coal per hour, obtained an average of 78.4 per cent of the builder's rating and used 1.86 in. of water pressure at the tuyeres. This was an experimental mixture made to see what it would do.

An average of seven tests with prepared anthracite screenings of No. 2 and No. 3 buckwheat and bird's-eye without any soft coal gave the following results: efficiency 59 per cent, evaporation from and at 212 deg. per lb. of dry coal, 7.47 lb.; ash averaged 14.5 per cent. We consumed 742 lb. of coal per hour, obtained 96.7 per cent of the builder's rating and used 1.73 in. of water pressure at the tuyere blocks.

We made one test using one-half culm and one-half buckwheat, which gave an efficiency of 53.2 per cent and obtained an evaporation of 6.13 lb. from and at 212 deg. per lb. of dry coal. The ash averaged 21½ per cent. We consumed 680 lb. of coal per hour and obtained 72 per cent of the builder's rating. To do this we used 1.87 in. draft at the tuyeres. The culm, of course, has a tendency to pull the buckwheat down.

In order to burn anthracite screenings and refuse successfully under our conditions, a Coxe stoker specially built for this grade of coal should be used, or a small amount of soft coal must be mixed in. This mixture must be maintained at all times and the better the mixture the better the results of combustion, for the successful burning depends entirely on the mixture. In our case the coal is dumped in as it comes and we have to take it as it comes. It cannot be burned successfully by having a run of say two hours on hard coal and then a run with a mixture of hard and soft coal. The whole thing is to have a uniform mixture in order to make a steady fire.

Some of the buckwheat clinkers and some of it will break up into smaller pieces, mixing with the fire, which makes it hard to clean. The fire should not be disturbed any more than possible. It is not good judgment to use a slice bar more than is necessary. The fires should be kept medium and the hoe should at all times be able to touch the grate. When hot, this class of coal resembles sand and a hoe can easily move it when necessary and handle the dirt. The lighter the fire, the better are the results. Unless the firemen are watched they tend to carry heavy fires with more draft. With an 8-in. fire we can easily burn 1000 lb. of coal per hour using a 2-in. draft at the tuyeres. The coal should run as even in size as possible.

We can burn screenings successfully if we obtain 20 per cent soft coal. It is more economical to burn straight soft coal than screenings, unless the equipment is installed for the burning of this class of coal. Two years ago last April we ran on soft coal only. We burned that month 10,352 tons of coal as against 13,689 tons of practically hard coal (about 20 per cent of soft coal) this last April. Our steam load this year was 369,512 kw. hours less for the month of April, or about 12 per cent of the total steam load.

If we take hard coal at $6.25 per ton and soft at $10 it would make the balance in favor of soft coal, provided the load was the same and we took into consideration the added cost for boiler-house labor and handling ashes.

We recently got a cargo of Dominion coal which apparently is high in volatile. We burned this with buckwheat, a quarter of Dominion soft coal and the rest buckwheat, and we secured the best results that we have ever had. Dominion coal burned straight is poor coal because it clinkers badly, but it has a tendency to mix with anthracite, and the anthracite holds down the volatile elements.

William P. Frey.[1] There is only one kind of anthracite waste, and that is material containing 35 per cent or more of incombustible, be it chestnut coal or No. 4 buckwheat. Since

[1] Fuel Engineer, The Lehigh Coal & Navigation Company, Lansford, Pa.

the development of the process of cleaning No. 4 buckwheat (through 1/8-in. round mesh and over 1/16-in. round mesh) and No. 5 buckwheat (through 1/16-in. round mesh) these two products have gained a firm foothold and have come to stay.

No. 3 buckwheat and No. 4 buckwheat are two excellent stoker fuels, if there is a proper stoker installation. No. 5 buckwheat is too light for stoker firing and should be briquetted. To the users of soft coal, hand- or stoker-fired furnaces, I cannot too strongly recommend mixing No. 3 buckwheat or No. 4 buckwheat with their bituminous coal. The curves, Figs. 6 and 7, clearly indicate the possibilities of these mixtures for stoker practice although they pertain only to hand-firing practice. All prices are based on the following scale:

Buckwheat No. 1—$4.10 per long ton f.o.b. mines
Buckwheat No. 2—$3.30 per long ton f.o.b. mines
Buckwheat No. 3—$2.15 per long ton f.o.b. mines
Buckwheat No. 4—$1.25 per long ton f.o.b. mines
Buckwheat No. 5—$1.00 per long ton f.o.b. mines
Uncleaned Silt—$0.65 per long ton f.o.b. mines
Bituminous run of mine—$3.40 per short ton f.o.b. mines.

Firing of Anthracite Buckwheats

Table 7 represents the attempt to tabulate in an easily understandable form the practical operating condition of industrial power plants with highly varying loads. As it was found that a rate of combustion of 25 lb. of dry coal per sq. ft. grate surface was very economical for all sizes, this rate was adhered to as closely as possible by adjusting the speed of the grates and the air supply. As a rough guide for the boiler operatives the blowers have to be set to deliver 20 cu. ft. of air per maximum horsepower. The air control goes hand in hand with the CO_2 recorder readings that read 12 per cent on the average and the stack temperatures which are to be kept below 500 deg. fahr. If the stack temperatures are high, the speed of the grate must be increased, the thickness of the coal fuel bed reduced, the air pressure under the grate lowered, but the rate of combustion maintained as constant as possible. It is very important to understand that the figures given in the column for grate travel in feet per hour are relative to 25 lb. of coal per sq. ft., which means that if the grate runs at 16.2 ft. in case of No. 3 buckwheat, the bed must be carried 6 in. thick. If it is desired to carry only 4 in. the speed of the grate must be increased 6 : 4 = 1.5 times to keep the same rate of combustion. It has to be understood, too, that 25 lb. per sq. ft. is by no means the highest possible rating. The maximum rating obtainable according to our experience is:

No. 1 Buckwheat—40 lb. per square foot per hour
No. 2 Buckwheat—35 lb. per square foot per hour
No. 3 Buckwheat—30 lb. per square foot per hour
No. 4 Buckwheat—27 lb. per square foot per hour
Uncleaned silt and No. 5 Buckwheat—25 lb. per square foot per hour or less.

These figures apply to a Coxe stoker with 7 per cent air space in the grate.

Good practice will keep the air pressures in the tuyeres as near as possible to 1 in. at the stoker front, graduating down to 0.2 in. at the refuse end of the grate.

The operating equipment includes: automatic feedwater and damper regulators, recorders of steam flow, CO_2, feedwater temperature, steam pressure, and stack draft; draft gages and long-distance thermometers.

Firing of Anthracite and Soft Coal Mixed

Buckwheats No. 3 and 4 are well adapted for mixing with soft coal if they are clean and the mixing is well done. These two conditions are absolutely essential and cannot be emphasized enough. The method of firing need not be changed, although there should be a tendency to fire thin and to damp off. The green coal should be thrown on when the fire is white hot, after leveling, for instance, and then there will be a very pronounced coking effect that will bake the No. 4 buckwheat to a coarsely granulated fuel of about pea-coal size. The fire must be kept loose at all times and will stand very hard blowing.

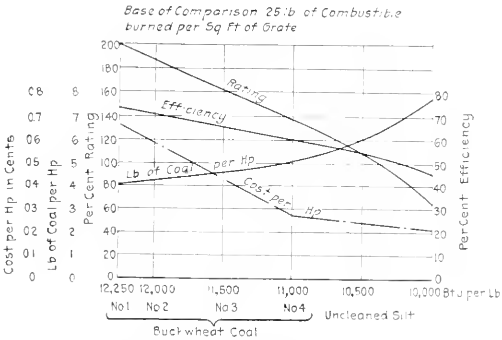

FIG. 6 PERFORMANCES TO BE EXPECTED WITH VARIOUS BUCKWHEAT GRADES

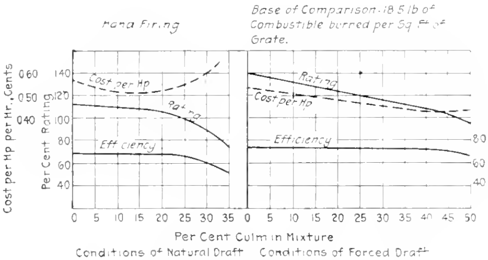

FIG. 7 PERFORMANCES WITH MIXTURES OF NO. 4 BUCKWHEAT AND SOFT COAL, HAND-FIRED

Almost any good grade of grate bar is suitable, up to about 3/4-in. openings, provided enough kindling is left on the grate after cleaning to cover the grate. The most gratifying feature of the mixture burning is that it does away with all hard clinkers, which is especially welcome in stoker practice, particularly in underfeed stokers.

The curves in Fig. 7 above show the results obtained in burning soft coal mixed with No. 4 buckwheat in a hand-fired Newburgh fire-tube boiler. The rate of combustion (amount of coal to be shoveled) was kept constant. All coal was crushed to smaller than 1 1/2-in. round mesh.

Briquetting of Anthracite Waste

Either No. 4 buckwheat, or No. 5 buckwheat, or the two mixed, or uncleaned silt, can be briquetted successfully. Anthracite briquetting has passed the stage of experimentation. The binder material is available, and with the concurrence of all concerned, not a pound of anthracite waste should go down

the rivers again. That briquetting is a commercial success is proven by the fact that it raised the price of No. 5 buckwheat from 65 cents to \$1, leaving still a small margin of profit, and by the ever-increasing output of our Lansford experimental plant, which shows the following tonnage figures:

1915— 3983 tons
1916—11,194 tons
1917—31,034 tons
Jan. to April 30th, 1918—18,500 tons

TABLE 7 OPERATING RESULTS OF ANTHRACITE BUCKWHEATS

750-HP. MAXIM BOILER—COXE TRAVELING GRATE. AVERAGE STEAM PRESSURE 125 LB.

	No. 1 Buckwheat	No. 2 Buckwheat	No. 3 Buckwheat	No. 4 Buckwheat	Uncleaned Silt

CONCLUSION

To the careful reader it will be evident from the preceding that it is not only desirable to burn cleaned No. 4 buckwheat, but it is at the same time most economical if ample grate capacity is provided; and there will go hand in hand with it the preparation of No. 4 buckwheat, and the washing and concentrating of No. 5 buckwheat, which can be briquetted to a very valuable fuel, relieving some of the domestic sizes. But the results obtained show still more conclusively how important it is to use proper methods of firing and mixing, and the prime importance of keeping the market free from all fake products of unclean No. 4 or No. 5 buckwheat, uncleaned silt, or low-grade briquets.

G. H. SHARPE.[1] The Derby Gas Co., Derby, Conn., endeavor to provide, during the season of open navigation on the Housatonic River, an ample reserve stock of bituminous coal to carry the electrical department through the winter and early spring. The demands during the past winter exceeded the estimate, owing to the emergency power supplied to Waterbury, Conn., and to tide over it was decided to accept an offer of about 11,000 tons of No. 2 and No. 3 buckwheat, on which deliveries started in the latter part of March. The 11,000 tons were purchased under three contracts, the average analysis of which is about as follows:

Ash, per cent...........................	20.52
Moisture, per cent.......................	8.20
B.t.u. dry	11,587
B.t.u. as received.........................	10,638

An average of 7000 lb. of buckwheat is loaded from the storage pile into a truck, and the truck is then filled up with bituminous, giving about 55 per cent of buckwheat per load. This is dumped at the power station, passing through a crusher and conveyor, and into the bunkers, resulting in a uniform mixture. From the overhead bunkers, the coal is delivered through a traveling weigh larry to multiple-retort underfeed stokers serving two 600-hp. Babcock and Wilcox boilers. The mixture is, as stated, about 55 per cent No. 2 and No. 3 buckwheat.

The fire carried is much thinner than with bituminous, and with a 2½- to 3-in. draft. The output of the boiler is reduced because of the lower heat value of the fuel.

The clinkers and ash are increased, resulting in a marked increase in cost of operation, as ashes are loaded by hand to trucks, pending completion of the new boiler room; but clinkers are more easily broken, so that less coke is lost in cleaning the dumping grate.

We are burning 2.20 to 2.21 lb. of coal per kw-hr. at the switchboard, with a maximum output of 6800 kw. and an average of between 5000 and 5500 kw., giving an overall plant efficiency of about 11.9 per cent.

The buckwheat costs \$1 less than the bituminous, but the increased cost of ash disposal and lower heat value do not warrant additional purchases. The stokers handle the 55 per cent mixture readily, and I have no doubt that we could have made an equal showing, based on heat values, with 75 per cent or even 85 per cent of buckwheat.

R. SANFORD RILEY[1] (Oral). We in the stoker business who are primarily interested in the burning of bituminous coal are frequently asked as to the amount of anthracite coal that may be mixed with bituminous. To answer this question intelligently, we should know the characteristics of both the bituminous coal and of the anthracite coal that the questioner has in mind. The proportions mentioned by the previous speakers are very good; we find that up to 30 per cent of anthracite may be used.

Nearly all stoker manufacturers are advocating the necessity for large stokers. We think that the stoker is really the limiting factor. The maximum of stoker capacity should be put under the boiler. The reason for this is that the boiler investment cost per horsepower is very much greater than that of the stoker. I would like to emphasize that the mixture of anthracite and bituminous must be thorough; one cannot burn first a patch of anthracite and then a patch of bituminous.

E. B. WESSON[2] (Oral). We have a small Manning boiler plant which we fire one-half anthracite and one-half bituminous; and we mix the coal by taking the small industrial dump cars and filling them half full of anthracite, and then at the other end of the trestle filling them with bituminous. The cars are then dumped on the boiler-room floor.

J. M. SPITZGLASS[3] (Oral). It is surprising that in all this discussion so far the boiler has been treated as a consumer, and a bad consumer at that. It seems to be overlooked that the departments that use steam should be checked as to the use they make of it. The instrument that saves the most coal is the one that measures the steam produced by the boiler and the steam that is used by each department in the factory.

A. G. Christie.[1] Last winter we purchased a considerable quantity of anthracite "yard sweepings" from domestic coal dealers for use in Taylor stokers under Babcock and Wilcox boilers in our University plant. This coal contained 16 to 20 per cent ash and averaged about 11,000 B.t.u. In general these screenings came from coal mined before the shortage occurred. It could be burned with perfect satisfaction in the stokers even at overloads when mixed as high as three parts of anthracite to two parts of Somerset semi-bituminous coal.

Later several cars of washed culm were purchased with from 25 to 40 per cent ash running 10,000 to 7000 B.t.u. per lb. The ash had a low fusing point and formed immense hard clinkers in the furnace when mixed and burned with semi-bituminous coal. It could only be burned with an equal portion of the Somerset coal when the demand for steam was small. In the furnace the fuel had a dull appearance and the finer particles tended to blow over on to the dump plates. It cascaded badly on dumping and during the removal of clinker. On the whole, we found the culm an uneconomical investment, although the yard sweepings proved economical when purchased at a reasonable price.

Carl Smerling.[1] Anthracite wastes such as culm and smaller sizes of buckwheat can be successfully consumed and burned, using a mixture of 1-3 anthracite and 2-3 bituminous coal, providing the bituminous is of a good coking quality and the fire can be carried 16 to 20 in. deep with natural draft of 0.7 in. at the stack breeching, and maintain a rating of from 125 to 150 per cent. On these conditions the stoker can be operated the same as when burning the straight bituminous coal fire. It is absolutely necessary to have sufficient bituminous coal to raise the temperature of the fire high enough to get all the value out of the anthracite coal.

5 What Instruments Are Useful and Desirable in the Boiler Room as Aids in Saving Coal?

What class of equipment has been of the most value to you, and how?

E. G. Bailey.[2] The answer to this question is: Meters that will actually *assist* the fireman to carry the load required of his boilers and at the same time obtain the maximum efficiency. The old idea of having meters and recorders to "show him up" if he did not do his work well, when he usually did not know how to do it better, is wrong.

The word "meter" is used here in its broad sense to include all instruments, pressure gages, thermometers, etc. down to coal scales and wheelbarrows when they are used to obtain knowledge of the operating and efficiency conditions.

Controllable Losses in Boiler Operation

In selecting meters, the principal object is to obtain knowledge of the boiler capacity and efficiency and also the individual losses, especially those which are controllable. To accurately know the losses is of much more importance than to merely know the efficiency, for efficiency can only be increased by reducing losses, and if one knows that the losses have been reduced, he is positive that the efficiency has been increased. The principal controllable losses in boiler operation are: (1) combustible in ashes and refuse, (2) excess air, (3) unburned gas, and (4) high temperature of flue gases. There are also other factors from an operating standpoint that are of importance, such as the steam pressure, superheat, rate of steam output from each boiler, evaporation per pound of coal, etc.

Meters are divided into four general types. Those which show condition; total; rate; relation.

Meters which show condition include pressure gages, thermometers, water level gages, etc. which in a boiler plant are used to measure steam and draft pressures; steam, flue gas and feed water temperatures; water level in the boiler and other similar factors. These meters may be either recording or indicating.

Meters which give total values or quantities, include coal and ash weighing or measuring devices, also integrator meters for water, steam, etc. These are usually indicating only.

Meters which show rate can be either recording or indicating, and include boiler feed, steam flow, air flow, stoker speed, etc. They may also be combined with integrating meters of the second type.

The three foregoing types are those with which we are most familiar and they have been developed and their general use extended in the same order in which they are named, while from an operating standpoint the value of these different types is practically in their reverse order. For instance, it is better for a fireman to know the rate of steam output from each boiler continuously than to wait until the end of his shift and learn the average rate from a water meter that integrates total only.

Results Should Be Known Promptly

The real valuable results from complete boiler tests, such as those made by Dr. D. S. Jacobus at Detroit some years ago, are not obtained until the many calculations involving averages and totals are made and the relations between the various factors is determined. In other words, the total evaporation or even the rate of evaporation gives no information whatever as to efficiency until we know how many B.t.u. were expended in producing this steam, or at least know how many B.t.u. were lost in making it. Time is an important factor in boiler operation and the fireman should know final results promptly and continuously. It is, therefore, desirable to have meters of the fourth type which indicate and record the relation between certain important factors as well as the condition, total and rate.

One of the important relations desired is that between rate of steam generation and rate at which fuel is burned. With liquid or gas fuels of uniform quality this is possible; but with coal, about the closest approach is the relation between a steam flow meter and tachometer on the stoker drive. The latter, however, is a crude means of determining the rate at which the B.t.u. are supplied to the furnace, and this is the real factor desired. It is doubtful if this will be satisfactorily attained, in the near future at least, due to the varying amount of coal fed per revolution of the stoker shaft and the varying quality of the coal, as well as variations in the amount of coal on the grate.

[1] Assoc. Professor of Mechanical Engineering, Johns Hopkins University, Baltimore, Md., Mem.Am.Soc.M.E.

[2] President, Bailey Meter Co., Boston, Mass., Mem.Am.Soc.M.E.

RELATION OF STEAM FLOW AND AIR FLOW

There is another relation, however, that is analogous to the steam-fuel ratio that is readily obtained and of even greater value. It is the relation between the rate of steam flow from the boiler and the rate of air flow which supports combustion for the generation of this steam. Air is a fuel just as much as carbon or hydrogen, and the amount of air required to develop a given number of B.t.u. is practically independent of the character or quality of coal being used. In fact, there is only 6 per cent difference between the B.t.u. developed per pound of air used to burn carbon and natural gas. This is much closer than most people are able to maintain the excess air in coal fired furnaces. Natural gas is mentioned in this comparison because it contains a higher percentage of available hydrogen than any other commercial fuel.

There is ample evidence available to show that the relation between the steam flow and air flow is of value in assisting the fireman to maintain the most economical fuel bed and prevent undue losses in either excess air, or unburned gases. This relation is also of great assistance to the fireman in obtaining maximum capacity from his boilers, for he quickly learns that it is impossible to make steam without the proper supply of air and if the maximum air supply is equivalent to only 200 per cent boiler rating, then 200 per cent boiler rating is all he can get, unless he is willing to sacrifice efficiency and produce high percentages of unburned gases. Such a loss is plainly shown by this relation as a deficiency of air.

Another important relation in boiler operation is that existing between flue gas temperature and rate of steam output. We have only to refer to data plotted by Mr. Azbe[1] to see that there is a wide difference between results obtained from various boilers in different plants. While this relation depends upon the position of baffling and other features of design, it is perfectly definite for any one design, and a certain flue gas temperature should exist for each rate of steam output. Any deviation from this indicates dirty heating surface or leaky baffles, providing the proper relation exists between the rate of steam flow and air flow. Either a decrease or increase in excess air from the most economical amount will result in an increase in flue-gas temperature, except that a large percentage of excess air will reduce the temperature.

In boiler-plant operation there are several other factors which should be combined to continuously show the relations existing between them for the benefit of the fireman or operating engineer, whereby they can get at the true conditions and their causes with little mental effort and delay. A meter which shows a relation is in reality an automatic calculating machine which takes two or more factors and produces a tangible result, which would otherwise require the reading of two or more instruments and reference to charts or tables.

The question often arises in selecting any of the four types of meters as to whether they should be indicating or recording. Some of the best power-plant engineers were strongly in favor of indicating meters for boiler plant work a few years ago, but have now changed to be the strongest advocates for recorders. Practically the only argument that can be advanced in favor of indicating meters is lower initial cost and the lower cost of operation by elimination of charts.

ADVANTAGES OF RECORDING METERS

Some of the many advantages of recording meters are: Permanent records to show conditions existing throughout the twenty-four hours; averages, totals and operating characteristics may be checked at any subsequent time: and of even more importance is the fact that it helps the fireman to see, not only the conditions at that instant, but also what the conditions have been immediately previous, and thereby ascertain whether they are changing, and if so, in which direction. This alone is of sufficient value to warrant the use of recording meters in practically every instance, providing they are located in the position where the man in charge of operation can readily see the chart record in detail. A water tender will do much better work when he has a recording feedwater meter within sight, than if the recorder were located in the engine room.

The firemen and operating men must have meters which serve as eyes whereby they can see through steam pipes and brick walls, so to speak, and actually know what is taking place. The meters that will give them true pictures in the most realistic and concrete form are the most useful in saving coal.

WALTER N. POLAKOV. While the generation of power, and more specifically of steam, is the domain of the scientifically trained engineer, power-plant practice is conspicuous by the lack of accurate measurement of conditions and results.

Unless the results attained are known, no opinion as to perfection of operation can be formed: furthermore, the practice is necessarily wasteful unless means are available to observe the conditions under which the process is performed. All instrument equipment of the boiler house can, therefore, be grouped into two classes: those for recording the results: those showing the conditions.

A plant of which it is not known how many pounds of coal are used per 1000 lb. of steam, how the load is distributed among the units and throughout the day, etc., by necessity wastes fuel. The knowledge of these data does at least open the eyes of those responsible for its success, and further progress is thereby made possible.

The first group of instruments then comprises:

Quantity
- Recording coal scales
- Recording steam or water meters.

Quality
- Coal calorimeter and moisture scales
- Feedwater thermometer
- Steam pressure gage and thermometer.

The second group of instruments is intended to direct the processes by controlling conditions:

Conditions
- Individual flow indicators
- Individual draft gages
- Individual flue-gas thermometers
- Flue-gas analyzer.

Substitution of flow indicators by coal or oil meters is undesirable, as it leaves obscure the output for given input: draft gages may be substituted by pitot tubes. Other modifications are sometimes desirable, but the above equipment is necessary and sufficient in general cases.

Any investment in instruments is a pure waste of money, and will lead to demoralization unless means are provided for:

a Training men to properly use them
b Stimulating men in the proper use of them
c Complete, exact, and continuous recording.

[1] Power Plant Efficiency, by Victor T. Azbe, Trans.A.S.M.E., vol. 38, 1916, p. 722.

Location and arrangement of instruments should be such as to:

a Permit simultaneous readings and their comparison
b Permit plain view of units from instrument board and vice versa
c Afford an opportunity to use one instrument for diverse units
d Eliminate unnecessary fatigue of observing scattered instruments
e Assure ease and simplicity for testing.

These requirements are combined in the type of instrument boards devised by the author, typical examples of installations being represented in Figs. 8 to 10.

The complete cost of such installations, including labor and material, averages $2000, and the returns secured on this investment are usually equal to or better than told in the following report from a plant using from 150 to 250 tons of coal per week:

" . . . . It is evident that in the four months preceding the installation of the boiler control board, the savings on fuel, due to various steps taken, averaged $435.00 per month, while, in the four months following the installation of the instruments, the savings computed on the same basis averaged $1145.00. In other words, the increased savings, due solely to the *intelligent use* of instruments on the boiler control board, was $710.00 per month, or $8620.00 on the annual basis, which means that the expenditure of $2080.46 for instruments of the said board is an investment which, in our case, yields over 400 per cent return."

The fallacy of economizing on instrument equipment or ignorant attempts to select "the most important" ones has only one rival in absurdity—the tendency of installing instruments without giving the employees the opportunity to use them to advantage. Obviously, the operating men have no time, no ability for research work, and little inducement, to carry out investigations, standardize methods, and set tasks. It should be the duty of the management to give them the necessary training and to assume responsibility for results.

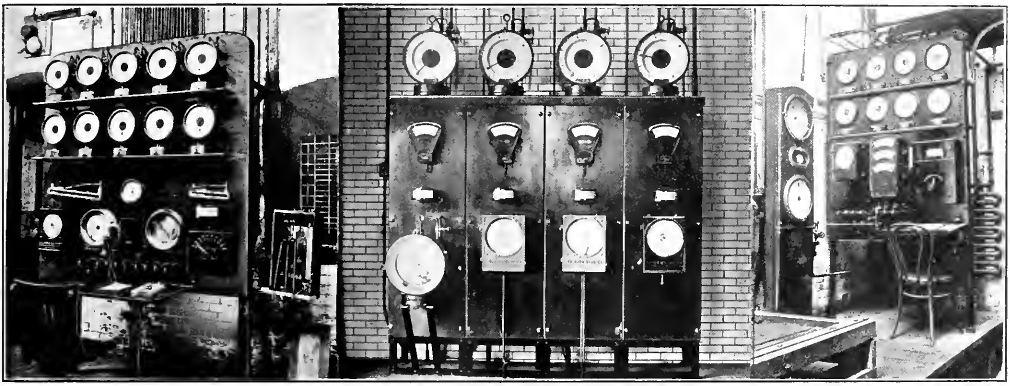

FIG. 8 FIG. 9 FIG. 10
FIGS. 8, 9 AND 10 BOILER AND COMBUSTION CONTROL INSTRUMENT BOARDS

A. R. DODGE.[1] Pressure gages and water-gage glasses are absolutely necessary to the operation of steam boilers. Next in importance is a steam-flow meter for the purpose of showing the amount of steam being delivered by each individual boiler.

Steam-flow meters in service have shown that in nearly every case a battery of boilers as a whole may be generating the required amount of steam, but the several boilers making up the battery fall far short of assuming equal subdivisions of the total.

Steam-flow meters installed on each boiler show at once a boiler which is "loafing," or one being forced too hard, conditions which cannot readily be detected in any other way. With this knowledge the necessary changes can be made in drafts, fires, etc., to equalize the steam output of the boilers. With the outputs equalized the danger of priming and burning out tubes and brickwork, due to excessive overload, is minimized.

Results obtained in many plants prove conclusively that the flow meters are a great aid to the firemen themselves in showing the results of their work. As soon as they learn that the flow meters show them the effect of changing the draft, fires, rate of feeding water, etc., they will be found using them as a working guide.

Holes and dead spots develop in fires, reducing the efficiency of combustion by allowing an excess of air. Should this occur, the steam output instantly drops and with a flow meter installed on each boiler, the fireman is warned that something is wrong.

Flow meters have been the means of indicating many other conditions which seriously affect the economy, such as leaky settings admitting quantities of air, burned-out baffles permitting a short-circuit of the gases, incorrect adjustment of feedwater regulators, or poor hand regulation, etc.

The use of draft gages, CO_2 recorders and a thermometer to show the superheat of the steam, in conjunction with a flow meter, enables the power-plant operator to keep a complete check on the performance of the boilers and furnaces, and to quickly eliminate faulty conditions as they occur and thereby to keep up the efficiency of the plant.

[1] Engineer, General Electric Co., Schenectady, N. Y., Mem.Am.Soc.M.E.

E. A. UEHLING.[1] The continuous CO_2 record shows up the process of combustion for every minute of the day. The indicator at or near the boiler front keeps the fireman continuously informed of what he is doing. It shows him in a few minutes the effect of any change in the rate of fuel and air supply that may be necessary to keep the steam pressure level.

[1] Uehling Instrument Co., Passaic, N. J., Mem.Am.Soc.M.E.

What the CO_2 Shows

In hand-fired boilers the continuous record not only shows whether the proper per cent of CO_2 has been maintained, but also how often the fire was replenished, how long the fire doors were kept open, when the fires were cleaned, how long it took to clean them, and the improvement in the fire resulting from it. With an occasional check analysis by an Orsat the continuous CO_2 record becomes an unchallengeable exposition of combustion efficiency.

Combustion efficiency is the foundation of boiler efficiency, but it does not necessarily follow that maximum combustion efficiency will always result in maximum boiler efficiency. There is another factor of nearly, if not quite equal importance, viz., absorption efficiency. Absorption efficiency depends, first, on combustion efficiency; second, on the relation of heating surface to the rate of combustion; third, the routing of the gases through the boiler; fourth, the cleanliness of the heating surface inside and out, and fifth, air infiltration. The CO_2 meter should therefore be supplemented by at least two other instruments, viz., the pyrometer and the boiler draft gage, preferably the draft analyzer, which shows both the furnace draft (resistance through the fire) and the boiler draft (resistance through the boiler). The pyrometer does not by itself give reliable information, but if its readings are coordinated with those of the CO_2 meter and the boiler draft gage, a complete and reliable control over absorption efficiency is had. The boiler draft gage gives immediate notice of broken down baffling, and in combination with the per cent of CO_2 its readings furnish an approximate index to the rate of combustion.

It would be useful to have, in addition to the above, a steam-flow meter on each boiler, since they would furnish a quantitative check on every boiler and fireman in addition to the chemical and physical qualitative control which I have mentioned as necessary and adequate to attain and maintain maximum boiler efficiency dependent only on plant—fuel—and operating conditions. The installation of a steam-flow meter is therefore to be highly recommended.

It is evident from all this that no boiler plant large or small should be without an Orsat, that the CO_2 recorder should take precedence over other more or less expensive equipment. Although the CO_2 recorder gives all the information necessary to control combustion efficiency, a pyrometer and draft analyzer are necessary in addition to control boiler efficiency. In general any instrument that will give useful information is a desirable addition to the equipment.

Wholesale control by means of water meter and coal weigher is most valuable to the manager in many ways in addition to those already mentioned, and any plant the size of which warrants the expense should install them.

There are many other instruments and apparatus of greater or less importance and utility which the prescribed space and time does not permit me to discuss. I may say, however, that all have their talking points and in a measure fulfil their advocated functions; but since they ignore the fundamental principle of combustion, they cannot give information adequate for complete control over boiler operations.

R. P. Brown.[1] The temperature in the furnace and the distribution of this heat throughout the boiler must be learned and studied carefully. The firebox is at such a high temperature that except for test purposes it is not practical to install an instrument at this point. An electric pyrometer can be used to secure by test the temperature in the firebox using a platinum-rhodium thermocouple, but most frequently the pyrometer is installed so that the temperature of the last pass, or in the uptake, is secured.

The temperatures in the firebox are approximately 2500 or 2750 deg. fahr., which is too high for a permanent installation. In the last pass the temperatures average about 1000 deg. fahr. and in the uptake about 400 or 600 deg. fahr. At these lower temperatures base-metal couples may be installed without danger of rapid deterioration. The temperatures in the last pass and uptake have been found to be comparative to those in the firebox; so that a working temperature is secured to which the fireman can work.

If actual practice shows that 500 deg. in the uptake or a corresponding temperature of 1000 deg. in the last pass of a boiler results in securing the maximum efficiency, then the fireman should use this temperature as a guide. The slightest irregularity in firing or change in furnace conditions are readily noted before the corresponding change in pressure may occur. If the flues are dirty and sooty the heat cannot be absorbed and instead pass up the stack, and a correspondingly high stack temperature is secured. If the baffle walls become cracked or broken down the heat will not circulate properly, and again high stack temperatures.

In addition to the usefulness of temperature and pressure recording instruments, there has recently been evidenced an increased interest in electric tachometers for registering the speed of the shafts on automatic stokers. The rate of firing naturally bears a close relationship to the amount of coal used. A small generator is attached to the end of the stoker shaft by means of gear or sprocket and chain drive. It is so geared that about 15 to 25 volts are generated at a speed of approximately 1000 r.p.m. of the generator. This voltage is carried to the instrument by means of wiring. As this can readily be strung for long distances, the instruments may be located wherever most desirable.

[1] President, Brown Instrument Co., Philadelphia, Pa.

C. W. Hubbard.[1] The evaporation figure might strictly be classed as a "half truth." When this figure has been arrived at, without supplementary data, one man's guess is as good as another as to whether the results obtained are all they should be.

The most useful instruments in the boiler room are draft gages, an Orsat apparatus, a CO_2 recorder, and recording thermometers for the feedwater line and the flue-gas temperatures. In addition to this, systematic tests of coal and ashpit refuse are necessary, for it is obviously unfair to expect the plant to operate at a given standard when it may be, and probably is the case, under present conditions, that the fireman is being furnished with greatly inferior coal.

It has been a common experience of the writer to be able by thus studying the preventable losses in the plant, to make a saving of from 10 to 20 per cent within a period of a month, and when I say 10 to 20 per cent I do not mean in power saving but I mean actual tons of coal wheeled into the boiler room.

R. H. Kuss. The question requires two sets of answers, because for the fuel engineer the entire range of instrument equipment may be made useful, whereas for the operating engineer of the usual grade, a very limited number of instruments are of any special service.

Instruments an engineer can use to advantage are those

[1] Fuel Engineering Co., New York City.

which he can understand: those that prove useful are such as require little attention to keep operating and which reveal maladjustment by simple test. The most useful and simplest instrument for the boiler room is a draft gage, preferably of the differential type. A draft gage or draft-gage system, if continuously used, will show to the careful observer—

a Developments of leaks, uncleanliness, baffle failures, etc.
b Poor fuel-bed construction.

Less difficult to interpret but much less useful than draft gages are thermometers or pyrometers. The difficulties in using pyrometers are those only of placing the bulbs or couples in the proper places so that the indication may be a true one of the condition investigated.

Gas-analysis instruments, while highly necessary for more refined investigations, are so seldom used by operators of plants of the middle or smaller size that as a general proposition it is useless to place them in the operating engineer's hands. The writer strongly endorses the use of coal-weighing and water-measuring systems.

The great difficulty with the subject is that, however useful the instrument may be, the supervising or engineering forces of boiler plants neglect to employ them to an extent their value justifies. The conclusion is inevitable that they should be few in number but of the recording type rather than indicating alone. The reason is that a record affords the opportunity of not only checking up the operating performance while going on, but gives the managerial forces the opportunity of checking up the operating engineering forces.

WALTER E. BRYAN.[1] When a number of boilers are connected to the same stack, it is particularly advisable to have each boiler equipped with a draft gage so that the gas passages can be regulated in the individual boilers with the result that more work will not be required of some boilers than others. Steam-flow meters are also advisable in stations where turbines are used and the flow is not pulsating. Readings of stack temperatures, CO_2, etc., should be taken at intervals, the latter with a view to calling attention to leaks in settings, etc. A recording CO_2 instrument arranged with connections to the various boilers is a valuable adjunct to the fireman.

B. J. DENMAN.[2] I believe the most useful instrument in the boiler room to be the one which indicates the percentage of CO_2 in the flue gas. In larger stations, with boilers of 1000 hp. or more, an automatic CO_2 recorder is justified. In smaller units, each boiler should be equipped with a gas collector and the Orsat apparatus, to determine the percentage of CO_2. Samples should be analyzed at least once during each watch. We regard the steam-flow meter as essential and as important an instrument as an ammeter or a wattmeter on a generator, and even more important from an efficiency standpoint. It is important that efficiencies of all the boilers be known over a wide range of loads and that they be operated at the most efficient point. It is not of much value to determine the efficiency curve unless its indications are followed, and this can only be done by the use of a steam-flow meter. These will show not only the number of boilers to have in service, but the division of the load between the units. With the underfeed type of stoker, we believe it is necessary to have instruments indicating the draft over the fire and at the damper, as with this type of stoker practically balanced draft can be carried, and this is the furnace condition which is most conducive to economy, through a reduction in the infiltration of air. Flue-gas-temperature recorders are desirable, but not essential, as the release temperature will take care of itself, if the boilers are kept clean and operated at the most efficient point, except for short periods during the peak.

A. G. CHRISTIE. Our University plant contains Babcock & Wilcox boilers and Taylor stokers with steam-pressure regulation on the blast and a balanced-draft system on the flue-gas damper. We have found that the instruments which receive the attention of our firemen and enable them to obtain the best results are draft gages on the blast and over the fire, a pyrometer in the breeching and a CO_2 recorder. The latter takes much skilled attention but produces results. We have been experimenting with a new blast regulator which promises to give better results than the usual type. Steam meters combined with coal-weighing devices are most desirable additions to the plant. Then records of coal and water consumed can be posted daily for the information of the fireroom shifts.

C. E. VAN BERGEN. We regard the draft gage as necessary on every boiler. It is not possible for a fireman to know what amount of air is passing through or over his fires, by simply looking at them. A steam-flow meter is valuable in showing the output of each boiler and all plants, except small ones, should have a continuous record of CO_2.

It is our belief that any plant expending $5000 or more per year for fuel cannot afford to be without these instruments. The draft gage has shown us that we formerly did not have proper adjustment of stack damper and ashpit doors. The steam-flow meter has given us valuable information on our monthly and yearly output and the flue-gas analyzer shows us the result of careless firing.

6 What Is Essential to the Economical Operation of Hand-Fired Boiler Furnaces When Using Soft Coal?

Helpful hints as to firing methods, front or side; frequency of firing; management of dampers; cleaning, etc.

HENRY KREISINGER. The right proportion of the air supply to the weight of the coal burned is the most essential requirement in the economical operation of hand-fired boiler furnaces. The removal of ash from the furnace is done with the object of keeping unobstructed the supply of air through the fire. The fireman shakes the grate or cleans his fires because the ash and clinker restrict the supply of air through the fuel bed.

In the boiler furnace about 14 lb. of air are necessary to burn 1 lb. of the average soft coal. This air must be introduced into the furnace in such a way that it is brought in direct contact with the coal and the gases rising from the fuel bed.

[1] Supt. of Power Stations, United Railways Co. of St. Louis. Assoc-Mem.Am.Soc.M.E.

[2] Pres., Tri-City Railway & Light Companies, Davenport, Iowa. Mem.Am.Soc.M.E.

The Bureau of Mines has shown that in the hand-fired furnace, if the fuel bed is level and 5 to 6 in. thick, only about 7 lb. of air can be supplied through the fuel bed to each pound of coal burned. If an attempt is made to force more air through the fuel bed, only the rate of combustion or gasification is increased, and the ratio of the air to the coal burned or gasified remains constant.

The gases rising from the fuel bed contain a large amount of combustible, about 8 to 10 per cent of CO and practically no free oxygen. To burn this combustible an additional 7 lb. of air must be supplied over the fuel bed, and should be supplied in a large number of small streams and as close to the fuel bed as possible, in order that it may be mixed readily with the combustible. This air is introduced through the dampers in the firing doors, through the cracks around the firing door, along the side walls and the bridgewall, in some cases through special openings in the bridgewall, and very commonly through holes in the fuel bed.

Difficulty of Maintaining Proper Air Supply

In hand-fired furnaces it is difficult to maintain the 14-to-1 proportion of air supplied to coal burned, because usually the air is supplied continuously and at a uniform rate, whereas the coal is charged intermittently at intervals of 2 to 20 min. duration. The ash is also removed intermittently at intervals of 3 to 24 hours, depending on its quantity and character. It is this intermittent feeding of coal that makes the proper proportioning of air to coal difficult. From the fireman's standpoint, soft coal consists mainly of two kinds of combustible, namely, volatile matter and fixed carbon. The volatile matter is that part of the coal which is driven off as gases and tars when the coal is heated, whether air is supplied to burn them or not. The fixed carbon is that part which stays on the grate after the volatile matter has been driven off and until burned or gasified by the air flowing through the fuel bed. When the fuel is 5 to 6 in. thick the fixed carbon is not completely burned, but a considerable portion of it leaves the bed in the form of CO. In the first 3 or 4 in. above the grate the carbon burns to CO_2, of which a large part is reduced to CO in the upper layer of the fuel bed.

Thus, immediately after firing while the distillation is taking place, the fuel bed acts both as a gas retort and a gas producer; after the volatile matter has been driven off the fuel bed acts only as a gas producer. Therefore, immediately after firing sufficient air is needed over the fuel bed to burn the gas from the gas retort and also from the gas producer. After the distillation has been completed only enough air is needed to burn the producer gas. With a constant air supply over the fuel bed it is impossible to have sufficient air to burn the gases completely while the process of distillation is going on without having too much air after the distillation has been completed.

Adjustment of Air Supplied to Quantity Needed

In order to have the right amount of air in the furnace at all times, two methods may be used: (*a*) The air supply over the fuel bed may be varied during each firing cycle; or (*b*) the distillation or the gas-retort process may be extended over the entire firing cycle.

There are devices to vary the air supply over the fuel bed automatically which, with proper attention, give good results. However, with the ordinary hand-fired furnace the fireman can approximate their action by cracking the firing door for a short period after firing.

The method under (*b*) is probably more practicable. Each new charge of coal can be heated slowly so that the distillation extends over the entire firing cycle.

With the coking method of firing the coal is placed in large charges on the front part of the grate, where it is heated slowly. When the distillation is nearly completed, the coal is spread over the grate and a new charge placed near the firing door. This method is feasible for heating boilers, but is objectionable for power-plant boilers.

For power-plant boilers the most practical and economical method is to shorten the period of firing so that distillation extends nearly from one firing to another. In order to eliminate the danger of piling the fresh coal on top of coal from which the volatile matter has not been completely distilled, half of the grate area should be covered at a time—the alternate method of firing—and the firing be so timed that half of the grate area is distilling volatile matter all the time. This may require that the firing be done at about 2-min. intervals, or even more frequently. The charges, of course, should be small so that there will be no tendency of the coal to form heaps; they should be spread over the thin spots of the fuel bed, avoiding the thick spots.

Frequent firing reduces the chance of the fuel bed's burning out large holes, which would let into the furnace too large an excess of air. With the caking or coking coals the holes in the fuel bed may not always be due to coal burning out faster in the thin spots, but to shrinkage of the fuel bed, which causes cracks to form. Once a crack is formed, the air rushes through and burns the coal on each side of the crack, rapidly making it larger. This explains why with eastern coking coals it is much more difficult to keep the fuel bed free from holes than with the free-burning coals such as come from the Illinois coal field. Frequent firing and the alternate method, to some extent, reduce the harm that may come from holes in the fuel bed.

Effect of Frequent Firings

Fig. 11 shows the effect of frequent firings of Illinois soft coal on the air supply and the composition of the furnace gases. The points connected with the solid, heavy line are the readings of CO_2 taken with an interferometer, and those with the dotted line the indications of CO_2, shown at the same time by a Uehling CO_2 recorder. The interferometer gives the CO_2 contents in the gases at the instant when the observation is taken, but the Uehling recorder has a lag of about 7 min. and a tendency to average the CO_2 readings over the entire firing cycle. The time of firing is shown by the black rectangles at the bottom of the chart. The interferometer shows plainly very high CO_2 immediately after each firing, followed by a rapid drop. This variation in CO_2 indicates very little or no excess of air after firing and considerable excess immediately before firing. The drop in CO_2 is much more pronounced with the 5-min. firing periods than with the $2\frac{1}{2}$-min. periods, indicating that in the latter case the air supply is kept more nearly proportional to the weight of coal burned.

One-half of the air supply was introduced through the grate and the other half over the fuel bed through fourteen $1\frac{1}{8}$-in. nozzles. Both air supplies were measured. The nozzles were placed in the side walls and injected the air in horizontal streams close to the surface of the fuel bed. The grate area was 30 sq. ft. and the rate of firing was 22 lb. of coal per sq. ft. of grate per hour.

Firing Methods Which Give Good Results

Good results can be obtained with a fuel bed about 5 to 6 in. thick. Heavy fuel beds offer high resistance to flow of air, making it necessary to carry high draft in the furnace and setting. High draft increases air leakage into the boiler setting and causes losses from the large excess of air. Furthermore, thick fuel beds cause excessive clinkering and the high losses connected with the frequent cleaning of fires. Higher rates of combustion can be obtained with thin fires than with thick ones.

The draft damper should be so adjusted that the air supply through the fuel bed is always just sufficient to burn the coal at the same rate it is fired. The accumulation of ash and clinker on the grate will gradually increase the resistance through the fire, and the draft should be accordingly increased. Sudden large changes in the damper should be avoided.

Perhaps the best and most generally used method is where the live coals and coke are pushed or thrown to one side of the furnace, leaving the refuse, which is raked out. The clean grates are then covered with clean fire from the other side of the furnace, which is then similarly cleaned.

I believe that more fuel is wasted by operating with leaky boiler settings than in any other way. All boiler settings, therefore, should be kept up to the highest possible degree of tightness. This can be done by stopping up all of the larger cracks with some good filler and then applying a generous coat of a first-class plastic cement, which will effectually seal all small cracks and pores in the brick. The settings should be gone over at regular intervals by a competent man and repairs made where needed.

The most important thing, however, in the economical operation of hand-fired boiler furnaces, whether using soft coal or

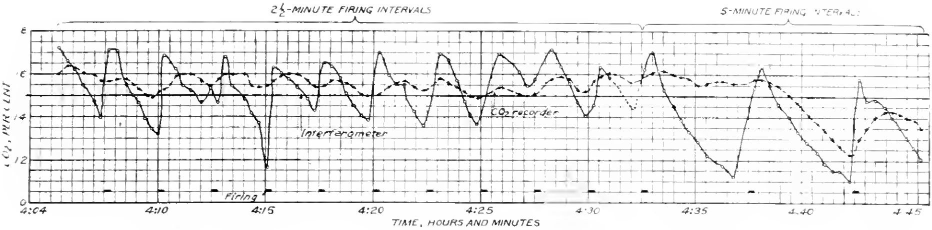

Fig. 11 Chart Showing Effect of Frequent Firings on Air Supply and Composition of Furnace Gases

Fires should be thoroughly cleaned at regular intervals and at times when the load on the boiler is reduced, such as the noon periods. The side cleaning method by which one side of the grate is cleaned at a time is recommended. After cleaning the fire should be built up gradually. A day's shift should start with a clean fire. Perhaps nowhere is a good start of such great advantage as in running a furnace.

Indicating Instruments of Prime Importance

E. E. Hunter.[1] One of the prime essentials to economical operation of hand-fired boiler furnaces when using soft coal is to have boilers and furnaces equipped with the necessary instruments as guides or indicators, of which a reliable CO_2 machine and draft gages are the most important.

The method of firing to be used depends largely upon the quality of coal and upon the nature of the load to be carried. For a steady load a slow-burning coal which cokes nicely may be used to advantage, because there will be no sudden demands for steam and a thick fire can be carried, which should not be disturbed except when absolutely necessary.

On the other hand, with an erratic, unsteady load a quick, flashy coal high in volatile matter will no doubt give satisfaction, and the fuel bed in this case should not be very thick and should be fired lightly and often according to the steam demand.

The alternate method of firing is recommended by some, but I believe the best one is to fire every door, with the fire doors kept open the minimum length of time. The firemen should be given long and careful instruction in the manipulation of the dampers, guided by the draft gages, and should regulate their draft according to the demand for steam.

Fires should be cleaned at a time when there is the least demand for steam, and as quickly and thoroughly as possible.

[1] Chief Engineer, Oklahoma Gas & Electric Co., Oklahoma City, Okla.

some other fuel, is to have a well-trained, efficient corps of men who are heartily in accord with their chief and his policies. This is extremely difficult to bring about, but it can be accomplished by systematic hard work, sprinkled with a little diplomacy. The governing head or superintendent, first of all, should be master of himself. This will command the respect and loyalty of those under his direct control. He should study human nature, for this will enable him to select the class of men who will stand by him. He, in turn, should stand by them, take an interest in their affairs, outside of business, and give ear and patience to any condition arising wherein their interests are involved.

George H. Diman.[1] This is a subject in which I have been very much interested for over fifty years, but I have been discouraged many times by the indifference shown by the managers and owners of power plants. I know of no department in any manufacturing concern where there is as much waste as in the boiler rooms of our manufacturing concerns in New England.

To get good results, the managers and engineers should coöperate. As an illustration of what I mean, let me say that I was employed in 1883 to take charge of eight mills, four woolen and four cotton, under two different agents, with the understanding that I should make a saving without spending any money for new appliances. The first six months before I took charge it cost $36,327.30 to operate the steam plant; the production of cloth was 812,363 lb. Every six months the power-plant cost was decreased, and for the six months ending November 30, 1884, the cost for operating the steam plant was $20,950 and the cloth production was 1,257,353 lb., this increase in output being due to the fact that more machines were running than when I took charge. The reduction of costs was accomplished entirely by systematizing the boiler plants

[1] Consulting Engineer, Wood Worsted Mill, Lawrence, Mass.

and by the aid of the managers of the mills. The same antiquated equipment was used throughout this period.

If I were to hire an engineer to take charge of a steam plant, I should have the man examined to see whether he thoroughly understood the economical burning of coal, and should be very careful to see whether he had tact in regard to handling men. It costs nothing to say "Good morning" to the humblest employee, and it should be remembered that there is just as warm a heart under the ragged shirt as under the best broadcloth.

In all the fifty years that I have employed labor, I have never gone outside the mill gate to hire any men—always promoting the men in the yard. This gives the men an incentive to work. As an illustration, the chief engineer at the Ayer Mills was formerly head fireman at the Wood Mills.

Before touching on the method of firing to secure economy, I will quote a letter from Admiral Cone of the Bureau of Steam Engineering at the time when he was chief engineer in the United States Navy:

Dear Mr. Diman:

We have had yours pertaining to economical burning of coal for some time, for which we thank you. We have already published it in our Bulletin to be used in the Navy. We thank you for helping us along.

Yours respectfully,

H. I. Cone.

So it will be seen that what I am going to say about methods of firing was approved and adopted as indicated by the above letter.

Firing Methods That Have Proved Successful

First, I should have the grates not over 7 ft. in length—$6\frac{1}{2}$ ft. would be better—as it is impossible, if the grates are longer than this, to keep the back end of the fire covered. I should set the boilers no less than 4 ft. above the grates—5 ft. would be better. This insures a good combustion chamber. It will be noticed that the boiler makers use practically the same size of ashpit door with a 250-hp. boiler that they do with a 600-hp. boiler. This gives a great supply of air near the doors, but none in the middle of the grates. I should dispense with the ashpit doors, cutting away the boiler front the full width of the grates. This gives an even distribution of air underneath the grates.

I should start with the fire 14 in. thick and try to keep it the same thickness through the day's run. I find time firing the best, and in our mills in Lawrence we adopted the system of firing every ten minutes, putting on the number of shovelfuls required to keep the fire the same thickness and maintain the power. I find that from 5 to 6 shovelfuls of coal is plenty. It takes about four to five minutes for a man to coal one side of two boilers and level the other side. This gives him five minutes to rest. I would recommend the boilers to be run about 50 per cent above rating. This would insure a very hot fire. Firing one side at a time prevents smoke. We have 44 boilers at our Wood Mills. They fire one-half of these boilers at a time—that is, one side, and level the other side of the same boilers. When they have finished, the men on the opposite side start and do the same. Every man has a chair to sit in, and in a 10-hour run the men are on their feet about half of the time.

I would use a good shaking grate which keeps the fire free from ashes, and would avoid slicing as much as possible, as this makes clinkers.

The dampers should be set so that all of the boilers will have the same draft. If the steam damper is used, I would have this adjusted so that it cannot close tight. When the damper closes tight, the furnace commences to make gas (CO), or utilizes 4450 B.t.u. instead of 14,400 B.t.u. We used to think that we were saving coal with the dampers shut, but we knew little about carbon monoxide then.

I should avoid cleaning the fires in working hours, preferring to clean them when the mill is stopped. If the fires must be cleaned while the mill is running, I would have one side of the fire burned down; clean the refuse and ashes out clear to the bridge wall; throw the coal from the other side that is unburned; coal that over, and when that is kindled up clean out the other side and coal that up. This insures a clean fire all over the furnace.

We hear a great deal about the great loss from opening the doors when hand-firing, but I have not found this to exist. If one will watch the operation of the steam-flow meter, he will find that the horsepower of the boiler does not drop when the fire door is opened. I have had both doors on a boiler open for one minute, and have seen no perceptible difference. The greatest loss comes from the uneven feeding of a boiler with water. I have seen the registration of a meter on a boiler drop from 500 hp. to 250 hp. in one minute, due to the fireman's opening the valve carelessly.

It is very necessary, in order to get economical results either with hand firing or stokers, to keep the boilers and the tubes perfectly clean, and to stop all air leaks around the boilers. On our boilers at the Wood Mills we blow the tubes every eight hours—three times in 24 hours, and open up and wash out the boilers every two months—that is, a certain number every week. We have very good water. If the water were bad, we would have them done oftener. I was once found fault with because the men used so many manhole gaskets, but I told the manager that manhole gaskets were cheaper than boiler makers. I never heard anything more about manhole gaskets.

7 To What Kinds of Plants and Coals Are the Different Types of Mechanical Stokers Respectively Adapted, and What Is the Limiting Factor to Their Use in the Small Plant?

Joseph Harrington.[1] The usual and generally accepted classification of coals from the viewpoint of the mechanical-stoker manufacturer and operative is based on the tendency of coal to fuse together upon the application of heat and form a solid mass, or piece of coke, which is impervious to air at ordinary draft pressures. Those coals which act in this manner are called coking coals, and to prevent this cementing action the fuel bed must be kept in agitation during the period when the tarry element is being formed. This feature has limited the field of the chain-grate stoker and those forms of this stoker which leave the fuel bed entirely quiet have been effectually excluded from the coking-coal territory. For this reason, those stokers which agitate the fuel bed and

[1] Member of Conservation Committee, United States Fuel Administration for Illinois. Consulting Engineer, Chicago, Ill. Mem. Am.Soc.M.E.

those which supply air under artificial pressure have been found most suitable to these fuels.

The success of the inclined and gravity underfeed stokers has been due in large measure to their adaptability to this particular characteristic of eastern coals.

Reclassification of Coals on Ash-Content Basis

Attempts by the manufacturers of this equipment to enter the high-ash and high-volatile regions of the Middle West have developed another significant feature which is becoming all important, and to a large extent is going to supersede the former system of classification. One of the characteristics of Middle West coals is the relatively high ash content. The use of stokers which disturb and agitate the fuel bed has shown in emphatic manner the importance and value of re-classification based on the ash element. This classification may parallel to a large extent that based on the coking qualities of the coal, heretofore regarded as the broadest division. Neither the coking nor the ash features afford a clean-cut and definite line of separation because the coals of the country are of all grades and intermediate qualities, and shade one into another by almost imperceptible gradations. Broadly speaking, there is a very definite difference between the coals found east and west of Pittsburgh.

I would, therefore, reclassify mechanical stokers along the following lines, and consider this classification as vital in their successful application to the immense territory lying west of the Alleghany Mountains:

While there are many variations in the design of stokers, they all fall into one of two classes; first, those having the grate surface immovable, or non-progressive, the fuel traveling bodily over the grate surface impelled either by purely mechanical means, or mechanical means aided by gravity; and second, those having the grate surface movable and traveling at the same rate as the fuel, the latter resting undisturbed thereon. Consideration will show that this is a basic stoker difference and hereafter must be given its full importance or value in assigning a type of stoker to a given region.

As previously stated, coking coals must be agitated during the early combustion stages and it is this which limits the application of the chain grate to the eastern fuels, and not the low ash content which is also characteristic.

On the other hand, those stokers which naturally and inevitably agitate the fuel get into trouble from this very cause when handling the high-ash western coals.

Fuel-Bed Disturbance Important Feature in Stokers

Extensive and careful observations impress me with the fact that the fuel-bed disturbance is and must continue to be the most important single element in mechanical stoking. When these fuels are burned at a rate which produces fusing temperatures in the furnace, the ash will either liquefy or soften so as to be sticky and the slightest disturbance will cause it to ball up and form clinkers of immense size. The more it is agitated, the worse this trouble becomes. At rates of combustion which are possible with the underfeed type of stoker a limit is actually reached, and the fire gets into such condition that operations must be stopped to allow the cleaning of the furnace. Even if it is possible to dump the refuse as formed, ashpit conditions become intolerable and it is almost impossible to remove the ash under these conditions. I am becoming convinced, therefore, that the efficiency of the otherwise highly efficient type of stoker, which we know as the underfeed or inclined type, is largely offset by the unavoidable ashpit losses and the excessive amount of labor which must be expended in removing the hot ash and clinkers, which come from these stokers, and in controlling the side-wall accretions. Observations accompanied by analysis both under test and under ordinary operating conditions show that from 20 to 50 per cent of combustible will be found in the ash, and that this represents anywhere from 3 to 6 per cent of the total coal fired. It is possible to burn such high-ash coals with not to exceed 20 per cent of combustible in the refuse and when conditions are right 10 per cent can readily be obtained.

I should, therefore, like to call attention to this fact and suggest that the ultimately successful stoker for the region lying west of Pittsburgh will be one which does not agitate the fuel, and which discharges the refuse as formed and at the same time does not admit to the furnace more than the usual requirements in the way of air. It is possible to burn these fuels on this type of stoker with the proper amount of air per pound of coal, and when the draft is intensified by mechanical means, rates of combustion in conformity with modern requirements can be developed.

Great stress is invariably laid upon gas analysis, and without question it is a most important index of furnace efficiency. Recent developments, however, have shown another and serious source of loss, which, while it has been recognized, has not been given its proper weight. The ashpit is the source of loss to which I refer and before conservation can properly be carried out, this loss must be largely eliminated.

The answer to the question as to the minimum size of installation which warrants the application of mechanical stokers must be relative and not absolute, since there are at least two variables which enter into this combination.

Any application of mechanical stokers which pays for itself in three years is warranted. Paying for itself may be made up by reduction in the cost of the coal used, in a reduction of the labor required in operation, or both. A stoker will use up its value in fuel three times a year so that it is only necessary to secure a relatively small reduction in the price of coal to show a large profit on the cost of the installation. Labor enters into this proposition almost as importantly as does coal, since the supply of labor is becoming scarce and higher priced every day.

The great thing, however, for the country to consider at present is the opportunity which undoubtedly exists to burn lower grades of coal in a fairly economical manner, by the use of proper stokers, than can be burned in the hand-fired furnace. Coal which ordinarily would be classed as refuse, containing 40 per cent in ash, 7 per cent in sulphur and 15 per cent of moisture as fired, is being successfully burned in more than one plant.

The Field for the Mechanical Stoker

It would be practically impossible to develop rating by hand firing this fuel. If, therefore, the small hand-fired plant ordinarily accustomed to burning a good grade of lump or sized coal can secure a supply of screenings, even though they be of a low order, and provided they can be purchased at a reduced price, it can well afford to install a mechanical stoker. It is recognized that the small stoker costs out of proportion to its active grate area but at the same time the percentage in saving may be greater than in the case of the larger installation because the fact remains that the small installation is usually the worse offender from an economic standpoint.

Authentic cases of 25 to 30 per cent reduction in the cost of coal abound when this change has been made. From a theoretical standpoint, at least, there is no minimum limit in the practical size of steam boilers suitable for the application of mechanical stokers. Merely because stoking has been developed with the larger units is no reason why it should not be developed for the smaller unit, and in consideration of the large percentage of the total fuel supply that is consumed in the very small plant, it is imperative that engineers give this phase of the question their earnest consideration. If the stoker does not exist which is suitable to a 50 or 75-hp. boiler, it must be developed, and my prediction is that it will soon appear on the market in perfected form.

The answer, therefore, to this part of the question is literally that there is no minimum limit to the size of boiler adapted to the use of a mechanical stoker; but interpreting the question as it will ordinarily be, my opinion is that anything over 150 hp. becomes a possible field for the application of the stoker.

J. VAN BRUNT.[1] The selection of mechanical stokers with regard to coal and size and character of plants presents a problem that can only be answered in each individual case, and the proper solution can be reached only when all of the factors entering into the problem are known.

It is hardly advisable to arbitrarily classify plants, stokers and coal and attempt to predetermine on the basis of such classification the proper mechanical stoker. For the purpose of discussion, however, stokers and coals may be classified, and in a general way plants may be divided in four classes: Underfeed stokers; traveling or chain grates; overfeed stokers, and miscellaneous, such as powdered-fuel burners, shovel or scatter stokers, and semi-mechanical grates.

CLASSIFICATION OF STOKER PLANTS

Underfeed stokers are again subdivided into multiple retort as the Riley, Westinghouse and Taylor; single retort with dead grates (Jones), and single retort with inclined moving grates as the Type E. Chain or traveling grates are of two types, differing principally in the fuel-bearing surface. In the chain grate the grate surface is composed of a large number of links held together by through bolts making a broad band of endless chain on which the fuel is carried. The traveling grate, on the other hand, consists of a number of grate bars or sections of grate bars held on cross-members, which in turn are fastened to the driving chains at either side of the stoker. The chains are thus below the fire line, and not subject to the heat as in the chain grate. There is a further division of such grates in forced-draft and natural-draft grates. Overfeed stokers may be front feed as the Roney or side feed as the Murphy and Detroit. The semi-mechanical grates and miscellaneous stokers need hardly be described further.

Coals present such a wide range of qualities aside from their approximate analyses and heating value that it is difficult to present a satisfactory classification.

COAL CLASSIFICATION

We have anthracite, semi-anthracite, semi-bituminous, bituminous, sub-bituminous and lignite. Recently coke breeze has become a recognized boiler fuel. As to size, anthracite steam coals are known as No. 2 buckwheat or rice, No. 3 buckwheat or barley, No. 4 buckwheat or No. 2 barley, and culm and silt, the last-named being a waste product now used as steam fuel only by some of the anthracite coal producers. Anthracites are also free-burning, and non-free-burning, clinkering, and non-clinkering. Soft coal is shipped as run of mine, slack, and nut and slack (also known as stoker coal).

Semi-bituminous and bituminous coals may be coking or non-coking or free-burning, caking or non-caking, high-ash, low-ash, and the ash may fuse at low or high temperatures. Sub-bituminous coal is generally free burning, but may be caking or non-caking, and will have great variation in ash content.

Lignite has the peculiar property of carrying as high as 30 per cent moisture held in the cellular structure of the coal, while in appearance the coal is dry. Its specific gravity is low, and volatile content equal to and sometimes greater than the fixed carbon. Air drying will remove nearly one-half of this moisture, but the lignite slacks badly in the process, breaking up into fine particles, which are extremely difficult to burn.

TYPES OF BOILER PLANTS

Boiler plants for the purpose of this discussion may be divided into four general classes as follows: First, low-pressure heating plants of one or two small boilers, including such small high-pressure plants of similar size as are found in some office buildings and factories where the load is small and the boiler set so low that a satisfactory stoker installation is impossible except at prohibitive expense; second, moderate-sized plants having ample boiler capacity operating at moderate ratings, and not requiring additional capacity; third, industrial plants of large and moderate size, requiring additional boiler capacity, where the labor may be materially reduced by stokers; fourth, central stations or plants having the characteristic load curve of such stations.

ADAPTABILITY OF STOKERS TO DIFFERENT REQUIREMENTS

In the first class of plants stokers are not, as a rule, adaptable to low-pressure boilers because of the fact that power is required to drive the stokers; and no saving in labor is possible, nor can stokers usually be installed except at considerable expense for changing the boiler setting or lowering the floor to secure sufficient height or distance between fire and shell or tubes of boiler. This latter condition also applies to high-pressure plants of similar character.

In the second class, the use of stokers would depend on the labor and coal saving possible. The load conditions and the coal available will determine the type of stoker. For steady, moderate loads and high-ash coal, the chain grate will be satisfactory; for some load conditions and good coal, the overfeed type. The underfeed type would also be satisfactory under most conditions, particularly where the coal is likely to vary in quality from time to time.

For plants falling in the third class, the forced-draft underfeed stoker will generally be found to be the most satisfactory because of its great flexibility, overload capacity and high furnace efficiency over a wide capacity range. This type of stoker will handle practically all coals between and including semi-anthracite and sub-bituminous with an ash content up to 15 per cent, and, except for high continuous overloads, 20 per cent.

For free-burning coal of higher ash content than 20 per cent, the forced-draft traveling grate would be a satisfactory

[1] Chief Engineer, Combustion Engineering Corporation, New York City. Mem. Am. Soc. M.E.

equipment, assuming that adequate provision is made to handle the ash.

Central stations and similar plants in the fourth class are practically forced to use underfeed stokers. Because of the low load factor of such plants it is essential that the stokers be able to force the boilers up to high overloads, 250 to 300 per cent of their rating for the comparatively short peak loads. It is also necessary at times to meet extraordinary loads with but little warning, and for this purpose the forced-draft underfeed stoker, because of its elasticity, is not equaled by any other stoker.

Starting from a banked fire with an underfeed stoker, it is possible to bring a boiler up to 200 per cent of rating in from four to six minutes, a performance not possible with any other type of stoker.

Where the coal has a high ash content and is of low heating value, it may be advisable to use traveling grates with forced draft. Sufficient grate surface can usually be provided to take care of the required overloads. This type does not respond as quickly as the underfeed type to sudden load changes, but where peak loads occur at certain known times they can readily meet such conditions.

So far the fuels considered have been those between and including semi-anthracite and sub-bituminous.

The successful use of mechanical stokers for burning the finer or steam sizes of anthracite is a comparatively recent development, and the writer considers himself fortunate in having been closely associated with this development. These fuels and coke breeze are now burned successfully on a traveling-grate stoker with forced draft. This stoker is the development of the work and experiments of the late Eckley B. Coxe, a prominent anthracite-coal operator. Many boilers equipped with these stokers and burning No. 3 buckwheat coal or coke breeze are being operated at from 150 to 200 per cent of rating. Because of the cost of the equipment it is not usually advisable to install in small plants or small boilers where only moderate loads are required.

This type of stoker is not as elastic as the underfeed, but is more so than the natural-draft chain grate. It would probably not meet satisfactorily the conditions of violently fluctuating loads.

Some recent experiments on this stoker have indicated the possibility of burning as high as 60 lb. of soft coal per square foot of grate, and in the near future there will be more data available on the burning of Illinois coal and lignite on this grate.

In existing plants among the principal limiting conditions found are the setting heights of boilers, the capacity of the breechings and stacks, the overload requirements, the kind of coal, the class of labor and the cost of the installation, and the foregoing classification of plants is only an attempt to generalize.

THOMAS A. MARSH.[1] The two general classifications of fuel from the standpoint of adaptability to stokers are: (1) coking and non-coking; (2) clinkering or non-clinkering. Compared with these characteristics all other properties sink into insignificance, as every experienced fuel burner knows. The writer would therefore discuss the stokers suitable for each of these classifications.

Coking coal is coal whose tars fuse at a temperature below their distillation point, resulting in binding the fuel together in a caked mass. Obviously, such a fuel-bed condition must either not be allowed to occur or it must be broken up soon after occurring. Stokers suitable to such fuels are underfeeds, inclined stokers similar to Murphy stokers, Roneys, L-type chain grates, Type E stokers. Almost all such fuels are found east of Pittsburgh, although some coking fuels are found in a few western sections.

LOCATION OF NON-COKING COALS

Non-coking coals are those whose tars distill off at a temperature below their fusing point. Such coals are, therefore, obviously free burning. The chain grate is well suited to these coals. The performance of the Commonwealth Edison Co. of Chicago is well-known and striking evidence of this

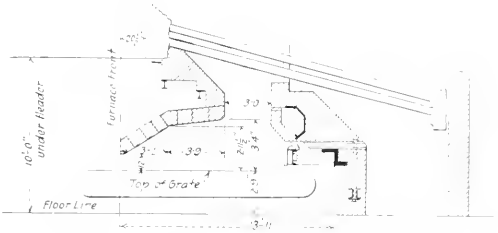

FIG. 12 CHAIN-GRATE SETTING, B. & W. TYPE BOILER

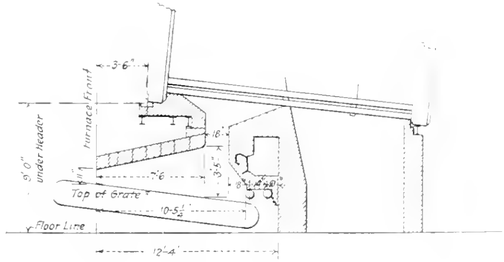

FIG. 13 INCLINED CHAIN-GRATE SETTING

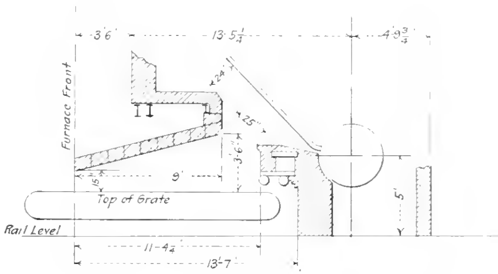

FIG. 14 CHAIN-GRATE SETTING—STIRLING BOILER

fact. Such fuels comprise most of the fuels of Ohio, Illinois, Indiana, Iowa and in general all coals west of Pittsburgh. Those types of stokers which do not agitate the fuel bed give best results when the coal is free burning. A characteristic of such fuels is the minimum of operating attention necessary and the uniformity of results obtainable with minimum attention. Bituminous coals above described are being burned to 14 per cent CO_2 with 3 to 5 per cent ashpit loss. Combustion rates of 30 to 50 per sq. ft. per hr.

[1] Engineer, Green Engineering Co., Chicago. Mem.Am.Soc.M.E.

Clinkering coals are those whose ash fuses at or below 2500 deg. fahr. Such fuels must be handled on stokers which clear themselves of ash continuously. If the coal in question is a coking coal, the fuel bed should be agitated. If, on the other hand, the coal is free burning, the fuel bed should not be agitated, as this simply aggravates the clinker trouble.

The work of the late J. P. Sparrow has been particularly helpful in aiding in the selection of suitable coals for certain stokers where a choice of coals is possible and a selection of suitable stokers for the available coal where a coal selection is not possible. Mr. Sparrow's tabulation of a variety of coals as presented before the National Electric Light Association in 1916 is given in Table 8.

Suitable stokers for coal that cokes and also clinkers are Green "L" type, Murphy, Model and Detroit.

Suitable stokers for free-burning clinkering coal include all chain grates and traveling-bar stokers. The argument is very strong, due to higher operating efficiencies, low labor cost and low maintenance cost against the reverse if agitating stokers are selected.

Suitable stokers for coking, non-clinkering coals are: Underfeeds, "L" type chain grates, Murphy, Model, Detroit and similar agitating grates. Such coals are New River, Pocahontas and the better-grade eastern fuels.

These are broad classifications. Local operating conditions may occasionally indicate exceptions to these selections. The

TABLE 8 COALS SUITABLE FOR VARIOUS TYPES OF STOKERS

Location of Mine.	Analysis: Moisture	Volatile Matter	Fixed Carbon	Ash	Sulphur	B T U	Fusion Temp.	Type of Stoker	Remarks.
Cambria Co, Pa	3.6	20.3	68.6	7.5	1.88	13710	2179		Very bad Clinkers.

The ash of most of the middle-west and western coals fuses from 2000 to 2400 deg. fahr. and some as low as 1800 deg. Clinker accumulations must be avoided. There are two methods of doing this. One is not to make the clinker, which necessitates that the ash be kept on the lower stratum of the fuel bed and out of the high temperature zone; the fuel bed must be undisturbed. The other method is to have a continuous discharge of the ash from the furnace.

The chain grate, which embodies both of these principles of keeping the ash in the low temperature stratum of the fuel bed and of discharging the ash continuously from the furnace, is suited to coals of the northern interior, eastern interior, Gulf, western interior, southern and Rocky Mountain fields.

one feature of being able to get steam quickly in case of a water-power shutdown would sometimes offset almost any difficulty with clinker and the resultant low operating efficiency.

We should not in our entire discussion of this problem lose sight of the commercial aspects of labor saving, ease of operation and maintenance of furnaces and continuity of service when stokers are using unsuitable fuels.

CARL SMERLING. The hand-operated stoker is now installed in all types of furnaces and almost every type of boiler from 40 to 600 hp. in one unit, and to the extent of 5000 hp. in one fireroom. This stoker could well be named

the Ford of stokers or more closely nicknamed the "Jitney."

I have no reason to believe that the hand stoker will ever be adopted or used extensively in any large power plant or central station, but believe that its place belongs in the smaller units of 500 hp. and below. These stokers are now in use under oil stills, oil-cracking furnaces for the production of gasoline, acid furnaces, in concentration furnaces, hot-mill and annealing furnaces.

The principal objects of this stoker are to obtain a more universal and complete combustion, increasing the efficiency of the boiler, and to reduce labor, thus eliminating carelessness on the part of the fireman, which is accomplished in doing away with the cleaning of fires by the old method, and by the coking method in which the coal is piled high in front of the fire doors.

Sifting out the ash from the clinkers finally deposits approximately 5 to 8 per cent of the total ash in clinkers at the bridge wall on the dump grate, where it is dropped at regular intervals as required. If red coke falls through the grate, it is an indication that the fireman must not pull the levers more but wait until the ashpit again looks a little dark. This pulling of levers as a rule requires one pull of each lever every half-hour, and on the average coal of 12 per cent ash the dump grate should be dropped once in 8 hr. After continuing this operation, it is possible to run water-tube boilers up to 225 per cent rating without difficulty, provided sufficient stack and correct flues are installed; at 175 per cent rating it is not unusual to obtain 72 per cent combined efficiency and a continuous high CO_2 of an average of 13 per cent.

One of the most interesting features of this "Jitney" stoker is the fact that the first cost of installation is very low compared with the saving over that of hand-fired flat or shaking grates.

ROBERT H. KUSS contributes the data given in Table 9 on the types of plants and qualities of coal for which stokers of different types are adapted.

TABLE 9 COALS AND PLANTS TO WHICH VARIOUS STOKERS ARE ADAPTED

Type of Stoker	Minimum size of unit	Minimum plant, hp	Maximum size of unit	Best coal characteristics	Unfit coal
Traveling grates	200 hp.	600	600 hp.	High volatile	Coking and low ash
Underfeed, Jones	150 hp.	300	300 hp.	Medium volatile	High ash, low-fusing ash
Combustion Engrg. Corp., Type E.	150 hp.	300	250 hp.	Medium volatile	High ash, low-fusing ash
Single incline	200 hp.	600	400 hp.	High fixed carbon	Low-fusing ash
Double incline	200 hp.	400	350 hp.	Medium volatile	Low-fusing ash
Inclined underfeed	500 hp.	200 0	Any larger size	High fixed carbon	Low-fusing ash

P. W. THOMAS. The stoker is restricted to a coal containing an ash which it will scavenge cleanly and without injury to its own metal. This brings a sharp division in the present types of stokers. Where the coal fluxes its ash at furnace temperature, a chain grate will invariably give the highest operating efficiency. Where the ash content is under 5 per cent or when the ash content will not flux at a temperature above 2600 deg. fahr., other types of stokers will give the same efficiency if properly handled.

The limiting factor in the use of the stoker in small plants is the cost of labor.

There is no *type* of fuel in the United States. Each field and each coal-producing district has absolutely individual fuel. The only comparison by analysis of the various fuels must be that analysis which shows, in addition to the usual proximate analysis, the quantitative analysis of the ash and its fluxing temperature. Given these figures, it is a matter of simple calculation to know which of the many stokers would perform so as to obtain the greatest percentage of heat to the boiler.

By the above let me explain that two bituminous coals showing the same proximate analysis may have entirely different ash contents, entirely different coking properties and attendantly different combustion rates. They both require the same quantity of air in the consumption of a pound of coal, but no device will cause one coal to unite with its given quantity of air in a shorter interval of time than its nature allows. The flexibility of a stoker, then, depends on how many pounds of coal can be supplied with the proper amount of air at one and the same time. Two methods are open: to increase the grate surface, or thicken the fire and apply the forced draft. In the latter case it is again necessary to figure the fluxing temperature of the ash in incandescent coke.

WALTER E. BRYAN. It has been common practice with Illinois fuel, where mechanical stokers are desired, to use chain grates. These give very satisfactory results, except that they cannot be forced to any great extent. Underfeed stokers should have a little larger size of coal, and also coal freer from impurities than that required for the chain grates. Stokers of the Westinghouse type have recently been used in this district on bituminous screenings with great success.

B. J. DENMAN. The chain-grate stoker is best adapted to coals containing 25 per cent or more of ash, due to the facility with which it disposes of the refuse. This is one of its chief advantages, and in addition to this it is one of the cheapest stokers available, and undoubtedly has the lowest cost of maintenance. From the operating standpoint, the chief objections to the chain-grate stoker are its lack of responsiveness and the fact that its point of best efficiency is rather sharply marked, dropping off somewhat rapidly at overloads and very rapidly at light loads. With proper care, good efficiencies can be maintained within a reasonable range of capacity, the low percentage of CO_2 which is obtained in most plants being unnecessary. The chain-grate stoker is practically smokeless. To secure the best results it should be set with flat coking and boiler arches of an inclination and length to best suit the fuel burned. This stoker is suitable for non-coking coals only. With coking coals it is impossible to get reasonable capacity, and the ash is practically pure coke. Chain grates which have been designed to burn coking coals have not been found to be successful.

The inclined overfeed type of stoker has the advantage of reasonably low cost but the disadvantage of high maintenance. Most stokers of this type require frequent poking of the fires, which produces considerable smoke. These stokers are not suitable for coals containing over 15 per cent of ash. They have a limited range of capacity, but are quite responsive to change in loads.

The inclined underfeed type of stoker has the greatest range

of capacity, the best efficiency of any stoker available, and the additional advantage that it is the most responsive to changes in load. Boilers can be raised from bank fire to steaming at the rate of 200 per cent in less than five minutes. This type of stoker has an unusually flat efficiency curve, with a high efficiency throughout the range, and with most arrangement of settings the highest efficiency is at light loads. This applies particularly to coal averaging about 11,000 B.t.u. and from 6 to 8 per cent ash. This enables a plant having evening peaks to eliminate the carrying of banked fires to meet the peak load, as it is possible to install sufficient stoker capacity to secure a boiler rating of 300 per cent.

The chief disadvantage of this type of stoker is its high first cost, but this is offset by the high capacities possible, which reduce the boiler-room investment. It is, of course, undesirable to operate the boilers at such high rating except for short periods, and for plants having no short peaks it would be uneconomical to put in sufficient stoker capacity to obtain these peaks. It has been my experience that considerably higher combined boiler and furnace efficiency can be obtained with this type of stoker than with any other type, and I have made extensive tests with chain-grate, inclined overfeed, and inclined underfeed stokers. This stoker is suitable for coals having as high as 20 per cent ash, but with coals running this high in ash, and with heating value as low as 10,000 B.t.u. per lb., it is necessary to arrange dumping sections of about twice the length normally provided, and to increase the height of the stoker sufficiently beyond the amount usually required, if very high rating is desired. We are carrying loads as high as 300 per cent rating with Illinois coal averaging about 10,500 B.t.u., with 15 per cent ash. The maintenance of this type of stoker is low as at present designed. This stoker is suitable for either coking or non-coking coals.

I do not believe the size of the plant determines whether or not a stoker should be used. This is more a question of labor conditions, load factor and funds available. We are at present operating a plant containing three 500-hp. boilers, hand-fired, while in an adjoining city of practically the same size we found it advantageous to install stokers. In that same city we are operating a gas plant containing two 200-hp. boilers, only one of which is in use at a time, which we have equipped with stokers.

A. H. Blackburn.[1] For the large electric-power plants with wide ranges of coal, and the larger manufacturing plants with boiler units from 500 to 2500 hp., the underfeed gravity and underfeed direct-push, self-cleaning stokers are the types of stokers best adapted, because they respond most quickly to the varying coals. They will show high efficiency for a range of from 80 to 200 per cent of rating. They will raise steam from no load to 200 per cent in a few minutes and are practically smokeless. They will successfully burn Pennsylvania, Maryland, Virginia, Ohio, Kentucky and Michigan coals.

The chain grates show best results when working at a steady load. They are adapted to free-burning coal high in volatile such as the coals mined in the Middle West; they are not so suitable for the coking coals having high fixed carbon.

The overfeed, inclined-grate and the side-feed stokers are adapted to boilers from 150 to 300 hp., and obtain their best economy when working from 80 to 100 per cent of rating and are not suited to heavy overloads.

The underfeed stokers and the combination of underfeed and overfeed stokers are suitable for boilers from 150 to 500 hp. and show excellent efficiencies at ratings from 80 to 150 per cent and can be worked up to loads of 200 per cent. The advantage of these stokers is the rapidity with which they will take care of sudden variations in load, the average good efficiencies obtained, and the comparatively low cost of repairs. They will successfully burn coals from Illinois, Kentucky, Ohio, Pennsylvania, Maryland, West Virginia, Iowa and Michigan. For internally fired Scotch marine boilers and internally fired vertical boilers of the Manning type the underfeed stoker has been successfully applied, showing results of 10 per cent saving over hand firing.

For the fair grades of lignite coals of the West, the underfeed stoker is being used with considerable success, especially when the fuel comes directly from the mine and before it dries out, by running light fires and rapid combustion.

As to the limiting factor in the use of mechanical stokers in small plants: Stokers can be applied with good results to boilers as low as 100 hp., especially when there is only one man employed to look after the boiler, engine and other apparatus about the plant, as hoppers can be put on that will hold an hour's supply of coal, or more; the automatic regulation will take care of the steam or combustion rate while the attendant is looking after other work.

Will Successfully Burn Green Lignite

Stokers have too often been applied under unsuitable conditions. Proper consideration has not been given to combustion space, the size of the unit and the particular design of the boiler to which the stoker has to be applied. The time has come when the first consideration must be given to proper design of combustion area to the particular quality of coal to be burned, and to the installation of boiler and stoker designs best suited to this condition.

8 What Experience Have You Had in the Use of Wood as Fuel? To What Extent Is Wood Available as a Fuel?

The coal shortage has occasioned the use of wood fuel in many unwonted places. Accounts of experience that will be helpful are solicited.

Robert H. Kuss. The writer's experience includes the burning of wood refuse coming from kiln-dried manufacturing operations of both hard and soft wood and "hog stuff" produced at logging mills in northern Minnesota. Kiln-dried wood refuse when burned alone constitutes no particularly difficult problem. If a sizable proportion is sawdust or planer shavings this material must be burned in a complete firebrick furnace, the fuel being introduced by gravity, and most of it being burned in suspension with very little air from the ashpit.

Where coal and wood refuse are burned together, difficulty is encountered if the major portion of the fuel is sawdust. Planer shavings in large quantities set up extremely difficult conditions. In any event, the combination of fuels must be

[1] Chief Engineer, Under Feed Stoker Co. of America, Chicago. Mem. Am.Soc.M.E.

burned in a complete firebrick furnace, so that the sawdust portion may be burned in suspension.

When "hog stuff" is produced from bark, edgings, etc. (as is the case in lumber-producing mills), it is best burned in a complete firebrick furnace where the fuel is introduced so as to form cone heaps over the grate surface, very little air being introduced by way of the ashpit, and the fire being most brisk at the grate surface around the edges of the cones.

Albert A. Cary. I have had to handle wood as a fuel under a wide variety of conditions which have called for different constructions in furnaces, as wood from a lumber camp, where undesirable tree trunks, boughs and branches were burned; in saw mills where the fuel was slabs, edgings and sawdust; in wood-pulp mills where the wood refuse was burned; in woodworking establishments where the fuel was the refuse from the saws, planers and other wood-working tools.

It must be remembered that fully one-half the weight of the wood is found in the volatile gases passing off during the process of combustion. With properly designed furnaces, the greater part of the air required for the combustion of these gases can be made to pass through the grates and fuel bed, where they become warmed to such an extent that they will not suppress the combustion of the gaseous portion of the fuel in the combustion chamber. An ample and well-designed combustion chamber is also essential to obtain efficient results.

Two objections commonly offered to the use of wood fuel are the production of objectionable smoke and danger from fire due to burning firebrands ejected from the chimney. With a properly designed and operated wood-burning furnace, however, the smoke nuisance can be so reduced as hardly to constitute a nuisance, and I have found no difficulty in stopping the trouble from sparks and hot cinders by using cinder screens enclosing the top of the chimney.

Heating Value of Wood Fuel

In the boiler-test code of the Society we have been instructed to regard 1 lb. of wood as equivalent to 0.4 lb. of coal; or, in other words, 2½ lb. of wood are equivalent to 1 lb. of coal.

The value of *dry* wood used as a fuel may be slightly greater or considerably less than this equivalent of bituminous coal, according to the design of furnace used and the manner in which the fire bed and its air supply are handled. The percentage of moisture carried materially affects the heating value of wood fuel, and therefore it is most desirable to have the wood as dry as possible.

Wet fuel, however, must often be used, and I have burned pulp-wood chips or shavings running as high as 30 to 40 per cent in moisture. Such very wet wood fuel must be burned in a reverberatory furnace with a heavy bed of burning fuel maintained, to dry the moist wood rapidly as it is fed continuously into the furnace.

Newly cut wood contains a large percentage of moisture, which varies in the different varieties of wood, but from one-third to one-half of this moisture will disappear if the wood is air-dried from six to twelve months.

Examples of Successful Wood-Burning Furnaces

In burning forest wood such as trunks, boughs and branches, I have found that much better results could be obtained with a wide furnace than with a long, narrow furnace in which wood is charged lengthwise through a front opening. With the long furnace it is difficult to maintain a good level fuel bed and have the grates evenly covered. I have obtained the best results for such fuel with a furnace about 5 ft. wide and 7 ft. deep. This had a charging door, running across the width of the furnace and about 12 in. high, which lifted vertically above the dead plate along the outer face of the front wall, being counterweighted and properly balanced, and the door was perforated with a number of ½-in. holes to admit and evenly distribute small streams of air over the fire bed.

The cut lumber was piled in front of the door so that it lay lengthwise, running from one side wall to the other. When the door was lifted the lumber, thus arranged, was pushed over the dead plate on to a grid of sloping grate bars dropping downward at an angle of about 30 deg. At the lower end of these sloping grates and about 18 in. from the bridge wall, I arranged another grid of sloping bars, dropping down from the bridge wall at an angle of 45 deg., thus forming a V-shaped grate surface having a long and short leg.

With this arrangement, the lumber was rolled or shoved down the bars from the dead plate in such a manner as to maintain a fairly thick and more or less compact fire bed over the lowest position formed by these sloping grates and very little difficulty was found in keeping the upper end of the grates (nearest to the door) covered with fuel. The charging door was kept open for the shortest possible time.

I designed and installed some very successful furnaces, built on the same general lines, for a large manufacturer of wooden cars, near Buffalo. The grates (under water-tube boilers) were placed a short distance above the floor level, thus obtaining a very high combustion chamber. An ashpit was excavated about 24 in. below the floor level with a trench along the outer face of the boiler fronts through which air entered. This trench was covered with removable plates in front of each of the large lifting, charging doors to permit easy cleaning of the ashpits.

The refuse from the woodworking shops was delivered to the boiler room through chutes and consisted of large and small pieces, chips, shavings and sawdust. The fireman piled the refuse in front of the upward-sliding doors, which were balanced in order to operate easily. When the doors were opened the fuel was shoved in quickly upon the large flat grate surface and the doors immediately closed. Two boilers, of about 200 hp. each, were operated in this manner most successfully.

In another woodworking shop in the West, manufacturing furniture, I supervised the installation of another form of wood-burning furnace placed under water-tube boilers.

Here the boilers were set very high above the grate surface and the wood refuse was continuously spouted down tube-like pipes, shooting into the furnace directly through the boiler fronts and landing upon the fuel bed below. A supplementary fire of coal was maintained upon the grates, and thus the plant obtained an ample supply of steam.

I do not know who was the designer of this system, but I protested against its installation on account of danger from fire running back along the wood-conveying spouts. About two years afterwards this plant burned and there was some question raised as to whether or not the cause was due to this system of feeding wood refuse to the furnace.

I have designed and supervised the installation of several different forms of extension furnaces for burning wood refuse, which have given satisfaction. Some of these have their fuel charged through top openings in the covering arch, above the

grate bar. The principal defect in this type of furnace is the pyramiding of the fuel on the grates directly below the stoke holes. This can be overcome to a large extent by building up a grate construction under the stoke holes, shaped like a pyramid. This insured a good penetration of air throughout the entire fuel bed and did away largely with the poking necessary to free up the other form of fuel bed.

Grateless Furnace for Wood Burning

One of the most successful forms of wood-burning furnaces for woodworking shops that I have installed is a grateless furnace similar in its general form to the well-known beehive type of coke oven. It is circular in shape, with a semi-spherical, dome-like cover over the top. I owe my first conception of this type of furnace to my friend, the late F. W. Edwards of the Standard Oil Company, who was deeply interested in the study of furnace equipments.

In this furnace the refuse wood is first run through a disintegrator, consisting of a disk having heavy knives inserted near the circumference of one of its faces. This disk is revolved at a high rate of speed inside of a casing, the larger pieces of wood refuse being fed into the disk chamber.

Thus the size of the wood is reduced until it is small enough to be carried by an air blast through conducting tubes. The end of these conveying tubes terminate in a centrifugal separator head, where the greater part of the air used for flotation is discharged. The wood refuse is then dropped through a tube from the bottom of the separator, accompanied by air under sufficient pressure to project the fuel into the furnace.

The wood passes into the furnace in a tangential direction, which causes it to travel around the circular face of the round furnace, and with the very high temperature maintained the wood ignites and burns very rapidly, somewhat after the manner in which pulverized coal is burned.

An opening, running in a normal or radial direction out of one side of the circular furnace, carries the burning gases directly into the firebox chambers of adjoining boiler settings.

A slowly burning fire bed of coal is maintained upon the grate bars of the boiler furnace and the combustible gases burn rapidly above this coal fire bed, without smoke production, and by this means the most efficient results are obtained from the wood refuse.

In case the supply of wood refuse gives out a damper is closed between the wood furnace and the boiler furnace and the boilers are operated in the regular manner with coal.

I have designed several variations in the construction of this type of furnace and in one case I fed wet spent licorice root down through the top of the furnace while operating the furnace proper in the way described above, with wood refuse from a large neighboring box shop.

A. G. Christie. At a recent meeting of the Baltimore Section of the Society, Mr. Henry Adams stated that he had burned wood on several occasions in furnaces designed to use soft coal and had obtained satisfactory results. However, only about 60 per cent of the rated boiler capacity could be obtained under average conditions. Another local member stated that he had found it advisable to lower the bridge walls when using wood in furnaces designed for coal.

9 What Coal Economies Can Be Effected in Residence Heating?

He who could make one ton of coal do the work of two during the past winter, not only conserved the coal for his neighbor and saved his own money but was comfortable when he might have otherwise been cold. How can it be done?

Frank T. Chapman.[1] According to good authority approximately 120,000,000 tons (2000 lb.) of coal is the present rate of use per year for domestic purposes in the United States. No accurate record exists to indicate what proportion of this coal is used for residence-heating purposes, but probably at least two-thirds, or 80,000,000 tons, of this amount is used for what might be broadly stated as residence heating.

The possible saving in coal used for residence heating may be divided into five principal items as follows:

1 Elimination of Heating for Unnecessary Rooms and Buildings:

a Shutting heat off from rooms not actually needed

b Closing of large residences where heating requirement is unreasonable for number of occupants or the rearrangement of heating equipment in order to heat only the portion of house actually needed for occupancy. (This item should represent a saving of at least 10 per cent.)

2 Lower Temperature Maintained in Homes:

a A 5 deg. lower average than past practice would save about 10 per cent of the fuel requirement.

3 Observance of Practical Methods of Reducing Preventable Heat Losses:

a Insulation of cellar piping, heater or other sources of heat loss

b Prevention of undue leakage at windows and doors.

4 Economical Operation of Heating Apparatus:

a The keeping of gas passages of heaters clean. (By far the most vital factor and the most important to emphasize.)

b Proper draft regulation

c Sifting ashes where they contain fuel value

d The study and application of available war coal-saving rules. (This item No. 4 should represent a possible saving of 20 per cent.)

5 The Use Where Available of Substitutes for Coal as Fuel, such as natural gas, kerosene oil, fuel oil, wood, peat.

A summary of these possible savings totals a proportion of about 50 per cent of the coal now used for residence heating. For practical calculation let us assume that one-half this proportion, or 25 per cent of the saving, can actually be effected, provided proper means are used to inspire, educate and require the public to take a more personal interest in conserving coal. Based upon 80,000,000 tons, 25 per cent would mean a

[1] Eastern Manager, American Radiator Company, New York. Mem. Am.Soc.M.E.

saving of 20,000,000 tons in residence-heating work, to which could undoubtedly be added a goodly percentage of coal now used for domestic cooking and hot-water service, by increased economy in its use and by a more extensive substitution of other fuels for cooking.

The practical possible saving on all domestic uses of coal would, therefore, appear to lie somewhere between 20 and 30 million tons. It is important to note that in this 25 per cent saving, only 10 per cent is figured as secured from "economy of operation," the remainder being mainly by elimination and lower maintained temperatures.

Having visualized the first two phases of the subject question, we come to the third phase, viz., the method of procedure that will bring about the greatest conservation. This phase is only indirectly covered by the original subject but is the vital factor which governs the proportion of the possible economies that can be effected.

An active educational program with punch and compulsion in it, as well as an appeal to patriotism, is required, and such a program must necessarily be based upon a plan of regulation and limitation of coal supply calculated upon quantities requiring economy. Only by such means can the average householder be aroused and impressed with the fact that if he does not study and apply the conservation rules, his negligence will react upon the comfort of his own family. He will run short of coal, while his neighbor who has observed the rules will have sufficient for his needs.

Information accumulated leads to the statement that a sufficiently consistent plan of apportioning coal for residence heating, cooking and hot-water service by regulation and limitation, can be secured to make the enforcement practical.

SAVING COAL IN HOT-AIR FURNACES

C. R. MUELLER.[1] In a residence of six rooms an estimated saving of 30 per cent of the coal was made last winter without any radical changes in the heating system. The installation consisted of an ordinary hot-air furnace using recirculated air. The means by which this saving was effected may be applied to practically all types of hot-air furnaces, to obtain as good and even better results.

One way of saving coal was to employ the alternate method of firing for the various poor grades of bituminous coal available. Instead of being spread over the whole surface, fresh charges of coal were thrown on one side of the fire only. The red coals left exposed on the other side ignited the gases distilled from the green coal, thereby saving the heat which ordinarily would have been wasted up the stack, in the form of unburned gas. Smoking was reduced and the usual explosion, which occurred just after firing, was prevented.

The fuel saving was further increased by lowering the room temperature below that required for comfort in ordinary residences. In residences where the humidity averages 20 per cent or less, during the heating season it is not comfortable unless the room temperature is at least 74 deg. By maintaining a relative humidity of 40 per cent a temperature of 68 deg. was found comfortable. In order to obtain this high humidity it was necessary to substitute for the regular water container pans with twice the evaporating surface, and set them close to the firepot. The pans were kept full by means of a float valve connected to the city water service. Since the amount of water evaporated was comparatively small, the coal consumed in this way was neglected in the following example.

[1] Detroit, Mich.

The calculation of the saving which resulted by operating at the lower temperature is based on the fact that the heat loss of a house is directly proportional to the difference in temperature between the inside and outside air. For this city (Detroit) the average outdoor temperature during the heating season is 37 deg. The difference between the inside and outside temperatures is 31 deg. for a house at 68 deg., and 37 deg. for one at 74 deg. The saving, then, by the comfortable house with 40 per cent humidity over the comfortable house with 20 per cent humidity is (37 deg.—31 deg.)/37 deg. or 19 per cent.

In addition to this economy there is, due to the increased humidity, a diminished susceptibility to colds and other pleural ailments.

Recirculating the air in a residence instead of drawing fresh air from outdoors results in a saving of coal, since less heat is expended in warming the inside air through the smaller temperature range. In regard to the healthfulness of recirculation, it can be no more objected to than in the case of steam-heated dwellings, which have no particular fresh-air inlet. Moreover, the air which leaks out of the cracks around the doors and windows is generally sufficient to supply many times more than the amount required for breathing.

The sluggish circulation encountered in the large majority of houses due to the poorly designed air ducts, results in a high stack temperature with its consequent waste of heat. A vigorous flow of air around the firepot and gas passages is necessary to take away this heat and carry it to the rooms above. Good combustion being maintained, the greatest saving of heat occurs when the stack temperature is reduced to the minimum required for draft. The writer made his largest saving during the past winter by using a 12-in. electric desk fan in the recirculating duct leading to the furnace. The fan was operated about fourteen hours daily, forcing twice as much air through the furnace as would have flowed naturally.

Several tests were made under various conditions, in all of which the superiority of forced circulation was obvious. In two consecutive 24-hr. tests, run to determine the economy of forced circulation, the results in Table 10 were obtained.

TABLE 10 TESTS OF HOT-AIR FURNACES

Kind of Circulation		Test No. 1	Test No. 2
		Natural	Forced
Duration, hours		24	24[1]
Average temperatures, deg. fahr.	difference, inside and outside	47	60
	stack	309	205
Total lb. coal fired		106.5	78

[1] The fan was run only 17 hr. of the 24 hr. of the test.

Reducing the coal consumption for the conditions of the first test to those of the second based on the ratio of temperature difference, we have $106.5 \times (60/47) = 136$ lb. The coal saving was then $136 - 78 = 58$ lb., which, at $\frac{1}{2}$ cent per lb., amounts to 29 cents. The cost of fan current at about $\frac{1}{4}$ cent per hour, or 4 cents for the test, makes the net daily saving 25 cents. The saving of coal expressed as a percentage was $100\,(136-78)/136 = 42.6$ per cent.

The few published results available on the performances of hot-air furnaces with forced circulation seem to agree to the extent that the efficiency is increased from 5 to 50 per cent by the use of a fan.

The means of saving coal in hot-air furnaces may be summarized thus:

a Alternate method of firing

b Maintenance of a room temperature of 68 deg. with humidity of 40 per cent

c Recirculation of air

d Reduction of stack temperature by forced circulation.

PHILIP J. SAVAGE.[1] Probably the best method of recommending possible economies in residence heating is to summarize briefly some observations and experiences extending over a period of six years and made in connection with the operation of a warm-air generator of well-known make, installed in a ten-room solid brick residence with average general exposure. Anthracite fuel was used exclusively.

Coal in each of the following forms has been given a full heating season's trial: egg size alone, egg and stove size mixed in equal portions, and stove size alone. Experience indicated that the stove size or smaller coal produces a more compact fire bed, and has the advantage of uniformity of burning rate causing less loss in the ashes. There was no appreciable loss of unburned coal through the grates with the stove size and, in a furnace of proper size, it produces flexibility and burning speed sufficient for severe weather. Incidentally, the cost per ton is lower for the smaller size.

The proper method of operating the grate shakers or revolvers should be carefully studied and the furnace maker's instructions closely followed. Great economies are possible here, in the lack of waste in the ashes. The variation in practice with identical apparatus is remarkable.

The necessity for a check damper in the smoke pipe, for purposes of economy, is obvious. The smoke pipe and its connection to the chimney should be free of air leaks, as the draft-checking effect may necessitate opening, more or less, the damper in the direct draft, which in most furnaces is designed to cause the hot products of combustion to bypass this damper section and flow through heat-absorbing chambers before admission, indirectly, to the smoke pipe. In the residence referred to, the damper in the direct-draft path is left in the closed position at all times of normal operation, except when the fire is being shaken down, and when coal is being added.

The prevention of air leakage at fireplace or grate openings by means of dampers or folding screens, at night and at other times when the ventilating effect is not necessary, is also valuable as a heat saver. Means should be improvised to prevent the all-night loss of heat through the open windows of bedrooms whose doors are left open, for various reasons, to the rest of the house. Stairways can often be more or less completely blocked by the use of a suitable folding screen, for example. In the residence in question, the morning temperature of the downstairs living rooms has been raised from around 60 deg., to 68 or 70 deg. by means of a screen placed nightly on a stairway, which effectively prevents the convection losses.

Relatively large areas of window and door exposure should be checked up very closely, as heat losses of great magnitude are occasioned by this means. The installation of weather strips on one door, and of storm windows on four large windows with severe exposure, in the residence referred to, effected very marked improvement.

The question of humidity does not seem to receive enough attention. The water pan in most of the hot-air installations, when present at all, is placed in the cold-air intake where the moisture absorption is almost negligible; and in installations of the hot-water or steam systems provision is seldom made for humidifying. At a nominal cost an efficient and automatic humidifying system can be installed in a hot-air furnace, with water pan in the dome above the firepot, where the moisture absorption is naturally greatest. Water pans, with some sort of simple wick arrangement to assist evaporation, placed beside the hot-air registers or over steam or hot-water radiators are appreciably helpful. In the installation under observation, a water pan in the air dome of the hot-air furnace and three pans, each with wick arrangement, placed beside floor registers, have increased the relative humidity during normal winter weather from an average of under 30 per cent to an average of about 45 per cent. An evaporation of over five gallons per day was secured.

By means of the changes above enumerated, in equipment and method of operation, the coal consumption in the residence referred to has been reduced from an established average of 16 tons per winter of average severity to 12 tons. The expense involved for the double windows, weather strips on a door, a new indoor air feed to the furnace and the humidifying apparatus was $50, and it has been an exceedingly profitable investment, aside from the added comfort obtained.

[1] The Detroit Edison Company, Detroit, Mich.

ROBERT H. KUSS. The writer has found success, when using bituminous coal of the non-coking variety (Illinois or Indiana, prepared sizes) by employing the following methods:

1 Attempt to operate throughout the heating season with the same height of refuse and live-coal level, this being two or three inches above the level of the bottom of the charging-door opening in the usual equipment.

2 Prepare for a new firing by crowding the live coal to the place nearest the firepot-chamber gas outlet. If the gases rise vertically over the entire firepot area, there is no choice in the matter.

3 Charge the green coal into the depression which should extend down to the refuse, thus permitting no contact with live fuel except on the surface nearest the placement of the live coal.

4 Regulate adjustments in draft for the period of a day's run by means of the check damper; regulate the maximum and minimum heat delivery (depending upon the severity of the season) by means of the chimney damper. In other words, the check damper is the daily, and the chimney damper the seasonal, draft appliance.

5 Admit very little air over the fire.

6 As the demands for greater or less heat delivery occur, vary the thickness of the refuse from 3 in. for greatest requirements to only a small live-coal area about 6 in. deep for mildest weather.

7 To facilitate refuse removal from the place of greatest accumulation, disconnect the bars of the other grate sections from the shaking lever.

8 Shake grates very moderately.

The results have been found to be, when compared with usual practice:

a Decidedly less combustible in the refuse

b Decidedly less clinkering

c Decidedly less soot formation

d More uniform heat delivery

e Substantial economy increases in mild weather.

DONALD B. PRENTICE.[1] The annual domestic coal consumption of the United States is estimated to be 1.1 tons per capita

[1] Assistant Professor of Mechanical Engineering, Lafayette College, Easton, Pa. Jun.Am.Soc.M.E.

of total population, and to be 1.4 tons per capita of those living in buildings heated by coal. These figures place the annual consumption for heating, excluding exhaust-steam installations, at 110,000,000 tons, including all grades of coal. If the average efficiency secured in boilers, furnaces and stoves can be raised from 45 to 55 per cent, for example, the same heating results will be produced with 90,000,000 tons. This reduction of 20,000,000 tons would decrease shipments by nearly 500,000 carloads, with an additional saving of fuel on the railroads. Under the present circumstances, of course, these 20,000,000 tons would be shipped as usual and diverted to industries where the need is severe, making an important contribution to relieve the industrial shortage.

Many residences are equipped with hot-water heating plants. A disadvantage of this system is the cooling of the large body of water during the night, and the consequent losses due to forced combustion in the morning, when an effort is made to raise the water temperature rapidly. The greatest cooling effect is felt in bedrooms, especially in children's rooms where windows are often open for twelve hours or more. All hot-water radiator valves when closed permit enough circulation to prevent freezing, which is necessary, but this circulation, unfortunately, is enough to reduce the temperature of the water in the entire system. The writer has found that closing bedroom radiator valves and then carefully wrapping the radiators with blankets will keep the temperature of the water in the system at least 60 deg. higher than it will be if the radiators are exposed to window drafts. If the water is at 140 deg. instead of at 80 deg. in the morning, fuel is saved and the living rooms are more comfortable.

On new installations with sectional boilers it is possible to have two distinct water systems, one for the living-room floor and one for other floors. This arrangement keeps the living-room circuit warm over night. It involves, however, considerably more piping and therefore adds to the cost.

The coefficient of heat loss from glass is four times that for the ordinary residence wall. If shades are drawn completely down after dark at all windows on the first floor and at all windows except those in bedrooms on other floors, and left down until morning, very valuable dead-air spaces are added to the glass areas, reducing the heat loss perhaps 50 per cent. This procedure also checks window leakage to some extent. Although living-room shades are usually drawn, the number of unshaded windows in most houses is surprising. Window shades are important factors in residence heating in another respect, the shutting out of sunlight. Part of the heating requirements of a residence can be met for many hours on sunny days by allowing the interior furnishings to absorb the radiant heat of the sun to the greatest extent possible.

A means of saving fuel in the furnace itself, which is not mentioned as often as it should be, is the use of small sizes of coal. It is quite practicable to burn anthracite as fine as No. 1 buckwheat on the ordinary shaking and dumping grate by carrying the fire on a bed of ashes, provided there is sufficient draft, which is usually true. This small coal, although higher in ash, can deliver as many heat units per pound as the larger sizes for three reasons: (1) For the same weight the coal has greater surface on which carbon oxidation can take place, which insures complete combustion; (2) the air passes through the fuel bed in fine streams and against enough resistance to keep the excess oxygen in the flue gas at a moderate amount; (3) the fire tends to spread over the whole grate quickly and without manipulation, which eliminates dead spots and prevents air leaks. These statements are not merely expressions of opinion, but conclusions from numerous tests.

Is it too much to expect of householders and amateur firemen that in the winter of 1918-19, by the use of small coal, by anticipating heating requirements and managing their fires accordingly, by eliminating or decreasing heat losses wherever possible, they will save the equivalent of at least one-fifth of the anticipated industrial shortage of 50,000,000 tons?

L. W. Eggleston.[1] The average rate of combustion in house-heating boilers is about 30 per cent of the rated capacity of the boiler. Most boilers develop their highest efficiency at their rated capacity, but to secure the most economical results the boiler should have its greatest efficiency at from 40 to 60 per cent of its load. All boilers designed for ascending gas

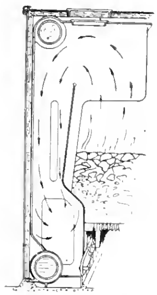

Fig. 15 Principle of Construction of Revertible-Flue House-Heating Boiler

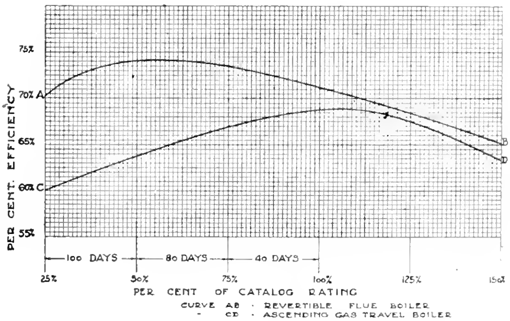

Fig. 16 Comparative Efficiencies of Revertible-Flue and Ascending-Gas-Travel Boilers

travel are most efficient at high rates of combustion; under low rates of combustion there is not sufficient volume of gases to fill all of the flue space. The gases pass to the chimney by the shortest route without giving up all of their available energy.

The most modern boiler construction is designed with a revertible flue travel, forcing the gases from their natural course. This feature properly applied to a boiler leaves no short cut for the gases to escape to the chimney. The floating effect of the gases while trying to resist the power of the chimney on their downward travel causes them to press against the heating surfaces of the boiler and give up their available heat under

[1] Manager, Sales Engineering Dept., American Radiator Co., Chicago, Ill.

all rates of combustion. This principle of construction is shown in Fig. 15.

Fig. 16 shows two efficiency curves. The lower curve shows the efficiency of a boiler with ascending gas travel. Its highest efficiency is at catalog rating. The upper curve indicates the efficiency of the revertible flue boiler, its greatest efficiency occurring at 50 per cent of catalog rating.

An important step in connection with a steam boiler is to free the system from oil and grease. Oily substances on the surface of the water in the boiler offer resistance to the generation of steam, producing an unsteady water line in the boiler and resulting in a wet-steam supply to the heating system. It has been frequently demonstrated that a greasy condition in a boiler has increased the fuel consumption more than 25 per cent and, unless the boiler is thoroughly cleaned after the plant is installed, the grease and oil will remain in the system indefinitely.

The most economical control for house-heating boilers is effected by allowing the greatest possible amount of the draft tension on the boiler at all times. The fire should be regulated by the draft door located in the ashpit. This door should be adjusted so that the maximum results can be obtained with the smallest possible amount of opening. With this control, excess air is prevented and good results are obtained at all rates of combustion. A great many operators imagine that by closing the choke damper in the smoke hood they prevent the heat from escaping up the chimney. This practice, however, decomposes the fuel without giving off its available heat.

It is very important that the boiler should be made airtight so that the air for combustion enters the draft-inlet door. Thermostatic control, properly connected to the draft dampers, effects a great saving in fuel and gives a more uniform heat.

It has been demonstrated by actual practice that this method of operation, compared with the average manner of operation, will result in a great saving of fuel.

P. J. DOUGHERTY.[1] At least 5 tons of coal per year are wasted in the average 10-room residence due to excess air leakage through loose fitting jambs, windows and doors. Assuming a clearance of $\frac{1}{16}$ in. around the windows and doors, the total area of such openings is equal to that of a 24-in. pipe. Allowing one-half of this area for air infiltration, at least 40,000 cu. ft. of cold air per hour enters the building, while 9000 cu. ft. per hour is ample for a family of five. In zero weather it requires about 5 lb. of extra coal per hour to heat this large amount of excess air.

The heat loss through an $8\frac{1}{2}$-in. brick wall and plaster is 1.8 times as much as through a 13-in. brick wall furred and plastered; or twice as much as through a $17\frac{1}{2}$-in. brick wall furred and plastered. In frame construction the heat loss through a wall consisting of clapboard, studded and plastered, is 1.4 times that through clapboard, paper, studding and plaster; or 1.9 times that through clapboard, paper, sheathing, studding and plaster. It is quite evident that a judicious use of building paper and interlocking metal weather strips are gilt-edge investments in reducing coal bills.

The next important leak to be stopped is the excessive escape up the chimney of unconsumed gases such as carbon monoxide, hydrogen, hydrocarbons and carbon. The fuel bed itself acts principally as a gas producer. About one-half of the heat energy of the fuel passes into the combustion space in the form of combustible gases. Unless the combustion conditions within the heater are right, these unconsumed gases carry nearly half the heat value of the coal up the chimney as a dead loss, irrespective of how low the smoke-pipe temperature may be. A high combustion temperature, not less than 1000 deg. fahr., is absolutely essential to produce economic combustion. Invariably a low combustion temperature accompanies a weak draft.

A weak draft, improper firing or faulty heater design are the usual causes of high coal bills because of unfavorable combustion conditions within the heater. The strength of a natural draft depends primarily upon the average temperature of the gases within the chimney, which should range from 300 deg. to 500 deg. fahr., depending upon the height of the chimney. Because of excessive leakage of cold air into the average chimney, and the maximum chilling effect due to the usual 4-in. chimney walls, it is no uncommon condition to have the flue gases chilled from 800 deg. to 200 deg. fahr. in passing from the bottom to the top of the chimney. This condition gives an average stack temperature of 500 deg. fahr., the requirement for the average low outside chimney 35 ft. or less in height. A properly designed heater will therefore permit the gases to escape to the stack at from 400 to 800 deg. fahr. in order to maintain the required temperature in the chimney.

Leaky chimneys are the bane of a heating engineer's existence. A heater cannot deliver heat to the system unless the draft is strong enough to first generate the heat from the fuel. A weak draft changes a heater from a heat producer to a gas producer. The combustible gases escaping up the chimney unburnt are the same gases that are purchased from the gas companies for cooking and lighting. A large saving in fuel and loss by fire could readily be accomplished if the Board of Underwriters as well as city ordinances and architects should demand a smoke test to prove a chimney tight before accepting it, as is the case in testing all plumbing and electrical installations before acceptance.

A strong draft properly controlled is the best fuel economizer on the market. In the average residence the available draft at the smoke damper should be about 0.2 in. of water. A sensitive draft gage of the Ellison type with a 15 to 1 ratio should be part of the equipment of every heater. No house owner can intelligently regulate the draft without a sensitive draft gage.

A strong draft not only saves coal by producing a high combustion temperature to burn the combustion gases, but it materially increases the effectiveness of the heating surface of the heater. The heating surface of the combustion chamber will absorb $2\frac{1}{3}$ times as much heat when the combustion temperature is 1350 deg. fahr. as when at 950 deg., the steam or water against the heating surface being at 212 deg. High combustion temperature is far more important than low stack temperature in burning fuel economically. It is far more economical to permit 20 per cent of the fuel energy to pass into the chimney as high stack temperature in order to produce the necessary draft, than to suffer the loss of 40 per cent of the fuel energy in the form of unconsumed gases due to a low stack temperature.

Excess air passing through the heater is a frequent cause of high coal bills. A thin fire on the grates, 12 in. or less, or a strong draft improperly controlled are the principal causes of heat loss through excess air as indicated by a low percentage of CO_2 (from 5 to 10 per cent) in the flue gases.

A deep bed of fire and ash on the grates at all times, from 16 to 20 in., will materially reduce the heat loss due to excess air. Excess air produces such a chilling and deceiving effect that more actual heat units escape from a heater whose flue gases show a temperature of only 300 deg. fahr. and 5 per cent CO_2, than escape from a heater whose flue gases show a

[1] International Heater Co., Utica, N. Y.

temperature of 800 deg. fahr. and 15 per cent CO_2. The former condition represents 19.6 per cent of the heat of the fuel, while the latter with its high stack temperature and low excess air represents only 18.5 per cent of the heat units passing up the stack as sensible heat.

B. J. Denman. The greatest saving in districts using bituminous coal for residence heating is to be obtained by encouraging the use of coke. In most residence heaters, the volatile matter is distilled off without being consumed, due to the general practice of filling up the furnace in endeavoring to cut down the frequency of firing. This can be avoided by advocating frequent and light firing of coal, or by the use of anthracite coal or coke. The use of thermostats for residence heating is very desirable, and would result in a material saving of fuel in the average house.

Most people do not appreciate the saving which can be effected by having a door or heavy curtain at the top of the stairway, so that the upstairs can be cut off. This makes it possible to heat only as much of the upstairs as is necessary, and prevents disagreeable drafts coming down, if the upstairs is not heated. It also prevents the chilling of the entire house, due to bedroom windows being raised during the night. An enormous saving could be effected if every one would cut off as many sleeping rooms as possible.

C. E. Van Bergen. Fuel may be saved in residence heating by using the smaller sizes of anthracite coal such as pea and No. 1 buckwheat. These can be used by careful handling of grates, taking care at all times to keep some ashes on or over the grates, to prevent the small coal falling through grates.

Do not shake or dump the grates roughly and if coal begins to run through grates, stop it by pushing down enough coal with poker to plug the hole.

Walter E. Bryan. Waste in residence heating is due, to a great extent, to ignorance of proper methods of handling heating apparatus. I have found that when it is not necessary to push the fire hard, the most economical results are obtained by keeping the ashpit door and firing door (including the slide) tightly closed and opening the damper in the smokepipe, which allows air from the outside to enter. The keeping of the fire door tightly closed may result in a little smoking immediately after firing, but it also results in a more even temperature and prevents cold air from being drawn in over the fire.

10 What Coal Economies Can Be Effected in the Small Steam Plants?

Plants which are not sufficiently important departments of their industries to warrant expert supervision and are too small to support real engineers waste a lot of coal and steam in the aggregate. What are the principal sources and methods of waste and how can they be avoided and corrected?

E. H. Kearney.[1] We would be lacking in the gift of foresight if we allowed ourselves to be lulled into the belief that at the present time, by virtue of existing conditions, a form of fuel conservation hysteria were sweeping over the country and that at the termination of a few months or a few years a return would be had to normal conditions—and to normal conditions is meant a relapse to pre-war price, production and consumption. In all probability, not in our day and generation will we again see the time when the commodities which enter into power-plant operation can be secured with the same facility which obtained previous to the present tightening-up-all-round period.

This is a thought which should occupy our minds to the exclusion of lesser things in dealing with present and future power plant conditions—we as engineers are the nation's fuel conservators.

In order to bring about the best possible efficiency in the plant, the operating engineer should, figuratively speaking, "camp" in the boiler room. Not a single detail of its operating conditions should escape his personal attention—methods of firing, condition of fires, leaks in settings, adjustment of draft, temperature of feed water and condition of feed pumps are but a few of the many things which should engross his attention. In short, the engineer does well who keeps constantly in mind the truth of the old adage, "If you want a good job done, take pains to do it yourself."

For several years preceding the war period there was a growing tendency upon the part of owners and engineers of medium-sized plants to install apparatus in the boiler room by which a closer check could be had upon fuel consumed, water evaporated, quality and temperature of gases, etc. Larger plants were equipped with these aids to economy as a matter of course, and the beneficial results which attended the operation of these more modern systems had set a worthy example for less pretentious plants to follow.

If increasing scarcity and cost of fuel had been the only factors to be dealt with, it is easily seen that firms dealing in scientific power-plant apparatus would have been swamped with orders. Had prices and delivery remained a fixed quantity, there would have been a scramble on the part of engineers of smaller plants to obtain apparatus which during the 24-hour period would enact the part of watch dogs of the coal pile. But while war conditions brought about a scarcity and soaring price of fuel, they also affected the apparatus manufacturer in like degree with the result that the modest plant owner found himself between two fires; either to install checking apparatus at a tremendously increased cost, provided he could secure it at all, or to continue under the old order of things by obtaining the best results possible with what he had in hand. Right here is presented a problem for the plant owner who is interested not only in the matter of his own fuel costs, but in the larger scheme of national fuel saving as well.

There is no question but that many plants which are now being operated without adequate provision for bookkeeping and cost checking could make a decided improvement in the appearance of the monthly balance sheet without the expenditure of extravagant sums. It should be the ambition of every power-plant owner and engineer to ascertain beyond reasonable doubt, through the medium of practical expert advice if necessary, whether or not his plant is being operated under conditions which square with good practice.

Reduced to its lowest terms the whole fuel problem as far as we engineers are concerned is just this: *Voluntary* fuel saving there *should be;* if not, *compulsory* conservation there *must be.* We as engineers must accept as a duty our share in the great task which now confronts the nation.

[1] Supt. of Bldgs., John Hancock Mut. Life Ins. Co., Boston, Mass.

D. C. Faber.[1] The possibility of improvement in boiler-room equipment and firing methods in small steam plants was very forcibly impressed upon engineers connected with the fuel-conservation work done in Iowa under the direction of the Fuel Administration last winter. In connection with this work, combustion conditions were investigated in about one thousand small steam plants, for the purpose of determining what could be done to improve boiler-room efficiency. While it is not possible to enumerate here the conditions found, there are a number of faults which are common to most plants of this type. In many of these plants the firemen have other duties which take them away from the boiler room for a great part of the time, so that firing instead of being a principal duty becomes merely an incidental one. Under such conditions the firemen usually do about all that is expected of them, which is to shovel enough coal from the pile into the furnace to keep up steam, regardless of how or when this is done, so that carrying too thick a fire, firing too large quantities at one time, and failure to regulate fire with damper in uptake are common faults. Air leaks in boiler settings, bare steam pipes and failure to remove soot and scale at frequent intervals account for a large percentage of the fuel losses in such plants.

Many of these faults can be done away with only through education of owners and operators. Right now, on account of the general interest in fuel economy, is the time to start such educational work. Supervision under direction of the Fuel Administration could well be a part of such educational work. Results can be secured now in the small steam plants which would be impossible under other circumstances.

Geo. H. Diman. One of the best ways to save coal is to save the heat units. This can be done in many ways. First, be careful not to have the rooms in the manufacturing plants overheated. Do not allow steam on in rooms with windows open. This summer, see that all the window frames are properly pointed so as to admit no cold air. If operating dyehouses, utilize all the available heat units in the dyehouse and finishing departments.

Let me illustrate what I mean. In one of our large mills, some years ago, the dyeing and finishing departments got behind with their work. In order to get the goods into the market we stopped the mill, running nothing but the dyeing and finishing departments. When the mill was running full we used about 6000 hp. and burned 1000 tons of coal per week. This power was generated by two pairs of cross-compound engines, sacrificing on the vacuum, and keeping the discharge water in the condensers at 110 deg. All this water was stored in the finishing department in tanks for washing the goods. A simple engine of 2400 hp. furnished exhaust steam for use in dyeing.

When we ran two weeks with only the dyehouse and finishing room we used direct steam, and ran only one engine. It took 275 hp. to turn the shafting of the dyehouse, and we burned 775 tons of coal per week.

It will be seen that in the first case, where the heat units were utilized as far as possible, we got 6000 hp.: while in the other case, where direct steam was used, we got only 275 hp. and burned three-quarters as much coal as before.

B. J. Denman. It is our belief that even in large plants, insufficient attention is paid to intelligent operation of the various boiler and engine units. Efficiency curves of boilers, engines and turbines should be made, and the units operated at their most efficient point. Great savings are possible in many plants if this is done.

One point frequently overlooked is the temperature of the hotwell in condensing units. The amount of circulating water pumped should be varied with the temperature of the circulating water, and the temperature of the hotwell kept as near that corresponding to the vacuum as possible, to reduce the heat loss to the circulating water.

A. G. Christie. This question was discussed informally at one of the meetings of the Baltimore Section last winter. It was pointed out that inefficiency in small plants was generally due to the following causes:

a Practically all horizontal return tubular boilers in the Baltimore district have been set too close to the grates owing to the fact that a local concern cast boiler fronts from a pattern which allowed only about 20 in. between boiler and grate surface. This had been increased in several cases to 6 ft. with decidedly satisfactory results.

b Air infiltration through cracks in the setting.

c Failure to keep the heating surfaces clean.

d Improper firing methods.

It was pointed out that economies could be secured by:

a Offering a bonus for coal saved.

b Keeping careful records of coal used and posting these.

c Providing a sufficiently large combustion space over the grates.

d Insisting on clean tubes.

e Using prepared mixtures to make the setting airtight. Several are on the market. The settings must be inspected periodically to see that they are kept tight.

f Elimination of steam leaks through joints, faulty traps, etc.

Carl J. Fletcher. The question as to coal economies that can be effected in small steam plants in the aggregate is one of the most important questions asked. The fuel cost in these plants is too small to permit the proper expert supervision and the possibility of saving much greater than in the larger plants. After an examination of a great many small plants, I have two suggestions to offer which would result in a very great saving:

Most plants clean the inside of their boilers fairly well; but it is my observation that when soot is removed by hand blowing (done at night when the pressure is low), it is one of the most neglected jobs around the boiler room. Automatic soot blowers should be installed and should be used several times a day.

One other possible saving is in the use of the damper on the individual boilers. Plenty of advice has been given regarding this feature, but I find in most plants that the dampers are inconveniently placed, and often not in real operating condition. As the first step, the plant management should insist that dampers are in good condition, equipped with levers which are within easy reach of the firemen. The damper should be easily controlled by means of a proper handle, placed where the fireman would not have to walk behind boilers to reach it.

P. W. Thomas. Economies approaching 50 per cent of the requirements in small steam plants of, say, 200 to 500 hp. can often be effected by simply putting the plants in shape. We have a record of one plant using 22 tons daily which now uses 11 tons, and the owners bought no fuel-saving equipment

[1] Consulting Engineer, U. S. Fuel Administration, Des Moines, Iowa.

except firebrick, baffle brick, asbestos and fireclay. The 11 tons were saved by the proper education of the men in the boiler room.

Walter E. Bryan. Probably the greatest loss in such plants is due to dirty boilers, improper firing and handling of dampers. If this fact, together with the remedy, could be placed in the hands of the managers of industries who are operating small plants, considerable saving would result.

C. E. Van Bergen. As long as the war lasts, no plant using coal for generating steam or for heating purposes can be considered too small to require the careful attention of some one within the organization. Fuel must be saved, no matter how small the quantity, and this is just the point which must be emphasized: "Every plant must save some coal." And along with this is another thought that, unless each one of us saves, we may experience a worse coal shortage next winter. And each of us should preach coal saving on all occasions.

11 What Experiences Have You Had with the Storage of Coal?

H. H. Stoek.[1] It is practicable, advisable and advantageous to store bituminous coal not only during war times, but also under normal conditions either at the mines, near the point where it is to be used: or at some intermediate point. It is well to store coal as near the point of consumption as possible to avoid rehandling and for the following reasons:

a To insure the fuel consumer of a supply of coal at all times

b To take advantage of lower freight rates, or of lower prices of the coal at certain seasons of the year

c To permit the railroads to utilize their cars and equipment to the best advantage

d To permit the mines to be operated more steadily.

Kinds and Sizes of Coal that Can be Stored

Although it is undoubtedly true that some coals may be stored with greater safety than others, the danger from spontaneous combustion is due more to improper piling of coal than it is to the kind of coal stored.

Most varieties of bituminous coal can be stored in the air if of proper size and if free from fine coal and dust. The coal must be so handled that dust and small coal are not produced in excessive amounts during the storing, because spontaneous combustion is due mainly to the oxidation of the coal surface.

All varieties of bituminous coal can be stored under water, which excludes the air and prevents spontaneous combustion.

The danger of spontaneous combustion in storing the coal is very greatly reduced if not entirely eliminated by storing only lump coal from which the dust and fine coal have been removed. Of two coals the least friable should be chosen for storage purposes, because less dust and fine coal will be produced in its handling.

Fine coal or slack has sometimes been successfully stored:

a By preventing air currents through the pile by means of a closely sealed wall built around the pile

b By closely packing the fine coal. Such a coal pile must be closely watched for heating. Piles of slack must be very closely watched for heating and means provided for promptly moving the pile if heating develops. The only absolutely safe way to store slack or fine coal is under water

c Many varieties of mine-run coal can not be stored safely because of fine coal and dust mixed with the lumps

d Coal exposed to the air for some time may become "seasoned" and thus may be less liable to spontaneous combustion, due to the oxidation of the surface of the lumps of coal, but opinions are by no means unanimous upon this point

e It is believed by many that damp coal stored on a damp base is peculiarly liable to spontaneous combustion, but the evidence on this point is by no means conclusive. It is safer not to dampen coal as or after it is placed in storage.

Effect of Sulphur on Spontaneous Combustion

It has been shown by experimentation that the sulphur contained in coal in the form of pyrites is not the chief source of spontaneous combustion, as was formerly supposed, but the oxidation of the sulphur in the coal may assist in breaking up the lumps of coal and thus increase the amount of fine coal, which is particularly liable to rapid oxidation. Even this latter opinion is not unanimously endorsed. In spite of experimental data showing that sulphur is not the determining element in spontaneous combustion, the opinion is very widespread that, if possible, it is well to choose a coal with low sulphur content for storage purposes.

Method of Piling Coal

To prevent spontaneous combustion, coal should be so piled that air can circulate through it freely and thus carry off the heat due to oxidation of the carbon, or else it should be so closely piled that air cannot enter the pile and oxidize the fine coal.

Stratification or segregation of fine and lump coal should be avoided since an open stratum or a chimney of coarse lumps of coal gives a passage for air to enter and come in contact with fine coal and thus to oxidize it and start combustion.

If space permits, low piles are preferable, as the coal is thus more exposed to the air and better cooled than in high piles, and in case of heating it can be more readily and quickly moved. A disadvantage in high piles is the greater difficulty of moving the coal quickly, if necessary. The idea that a high pile causes heating at the bottom is erroneous, since as many fires take place near the top as near the bottom and near the outside as near the interior of the pile. If possible, the coal pile should be divided by alleyways so as to facilitate rapid loading out of the coal in case of necessity, so that an entire coal pile may not be endangered by a local fire.

Much of the attempted ventilation of coal piles in the United States has been inadequately done by the use of only an occasional ventilation pipe which has been not much more than a place in which to insert a thermometer for reading temperatures. The practice of placing ventilating pipes close together has been used in Canada and is reported to have been effective.

Water is an effective agent in quenching fire in a coal pile if it can be applied in sufficient quantities, but a small amount is ineffective. Unless there is an ample supply of water to thoroughly quench the fire and cool the pile, it is very dangerous to add any water to a coal pile.

[1] Professor of Mining Engineering, University of Illinois, Urbana, Ill., Chairman of Fuel Conservation Committee, Fuel Administration of Illinois.

Coal of different varieties should not be mixed in storage if this can be helped, for one coal that has a greater susceptibility to spontaneous combustion than the other may jeopardize the safety of other coals that are not so liable to spontaneous combustion.

Effect of Storage on Value of Coal

The heating value of a coal as expressed in B.t.u. is decreased very little by storage, but the opinion is very widespread that storage coal burns less freely when fired in a furnace. Experiments indicate that much of this can be overcome by keeping a thinner bed on the grate than is kept with fresh coal and by regulating the draft.

The coking properties of most coals seem to be decreased as a result of storage.

The value of coal for making illuminating gas is not decreased as a result of storage.

The deterioration of coal stored under water is negligible, and such coal absorbs very little extra moisture. If only part of a coal pile is submerged, the part exposed to the air is still liable to spontaneous combustion.

Additional Precautions

The best preventive of loss in coal storage is to inspect the pile regularly and if heating occurs up to 150 deg. fahr. to keep very close watch on the pile; and if the heating increases to 175 or 180 deg., to remove the coal as promptly as possible from the spot affected, and thoroughly cool it before piling it again.

Storage appliances and arrangements should be so designed as to make it possible to load out the coal quickly if necessary, and the coal should not be stored in large piles unless provision is made for loading it out quickly.

Pieces of wood, greasy waste, or other easily combustible material mixed in a coal pile may form a starting point for a fire, and every effort should be made to keep such material from the coal as it is being put in storage.

It is very important that coal in storage should be kept from such external sources of heating as steam pipes, because the susceptibility of coal to spontaneous combustion increases rapidly with an increase in temperature.

T. N. Wynne.[1] The Indianapolis Light and Heat Company has been storing Indiana coal since 1888. Before 1912 all coal stored was on the ground in open air, with no particular attention paid to sizes, quality, or the method of storing. In 1912 this company investigated the question of storing coal under water to prevent spontaneous combustion and loss of heating value. No. 4 vein Indiana coal contains approximately 2 per cent of sulphur and No. 5 vein from 3½ to 6 per cent, and our experience has been that No. 5 will invariably fire if exposed to the air, while No. 4 will not. While we feel it safe to store No. 4 coal on the ground, it is so difficult to obtain that we feel it necessary to provide storage that will be safe for No. 5. We burn No. 4 on Roney stokers and No. 5 on Green chain grates.

An average of 741 tests shows the freshly mined No. 4 vein coal to contain about 35 per cent of volatile combustible matter. From tests of various samples taken from No. 4 coal stored for three years in open air at our Kentucky Avenue Station the volatile content was found to average 28.34 per cent, indicating a loss of 20 per cent. This coal during its period of storage did not show any signs of heating.

At the same station we have had stored for about eight months 2000 tons of No. 4 vein Indiana mine-run coal. This coal has never shown a tendency to fire, although in places it is 35 ft. deep.

The history of coal storage by our company has been a series of fires and losses. In 1912 we constructed at our Mill Street Station a concrete pit 300 ft. long, 100 ft. wide and 20 ft. deep, designed to contain 13,000 tons of coal submerged. A standard-gage track crosses this pit at ground level from one end to the other on concrete piers. The cars are run upon this track and dumped. After the coal has reached a certain height it must be handled to both sides of the track by means of a Brown hoist. The topography of the ground prevents the elevation of track to facilitate dumping, a condition very desirable if possible. The pit when filled is not disturbed except in case of shortage in daily delivery. Mine-run coal only is stored because screenings under water become a mud-like mass, almost impossible to handle or burn.

Capillary attraction will take care of coal piled above the water level of the pit as much as 8 or 10 ft., thus permitting of additional capacity of about 40 to 50 per cent.

Whenever coal is taken from the pit to be used on the stokers it is loaded into railroad cars and the water allowed to drain off for about six hours before the coal is put into the bunkers; or, when coal is to be taken from the pit the water may be lowered until sufficient coal has been uncovered and drained to meet the requirements.

The result of underwater storage fully met our expectations in that it prevented fires and preserved the heating value of the coal. We have never been troubled with excessive moisture when burning pit coal if mine run is used. Screenings which have been stored under water burn with difficulty.

A loss of heating value is very evident in the case of coal stored in air. In fact, when burning air-stored coal it is necessary to have additional boiler capacity to carry the same load.

Results of 181 tests of No. 4 vein coal which has been submerged for one year as compared with those of the 741 tests of freshly mined coal previously referred to, show a reduction of 1.7 per cent in available B.t.u. in the case of the submerged coal. This loss is so small that it might very well exist between two lots of freshly mined coal.

Recently we constructed a reinforced-concrete coal pit at our Kentucky Avenue Station, 145 ft. long, 65 ft. wide and 32 ft. deep, built on the same general lines as that at the Mill Street Station and holding 8000 tons.

The Indianapolis Light and Heat Company burns 500 tons of coal per day, and as the two pits have a total capacity of 20,000 tons of coal submerged and 10,000 tons above the water line, this means a sixty days' supply on hand if both pits are filled. The total cost of the two pits was \$60,000 or \$2 per ton of storage.

Albert A. Cary. Another phase of the coal-wasting proposition is that of spontaneous combustion.

With the clean coal formerly received by a certain large power plant, running low in percentage of non-combustible matter, trouble from spontaneous combustion was almost unknown even after the coal had been stored for six or seven years in dense piles.

With the coal now received they find that they cannot store it for two weeks without spontaneous firing; in fact, they have such fires burning in their coal bins almost continuously, with

[1] Indianapolis Light & Heat Co., Indianapolis, Ind.

the result that when this supply is drawn upon for use they have coke to burn instead of coal.

With the valuable heat-producing volatile matter thus distilled out of our eastern bituminous coal, the loss in steam-making capacity is from 10 to 15 per cent.

Should coals from the Central West be used (which coals contain a considerably higher percentage of volatile matter), the amount of such loss is materially increased.

Loss from spontaneous combustion simply means that a correspondingly *greater amount of coal* must be carried over our transportation systems from the mines to make up for the deficiency thus created.

The spontaneous combustion of coal is occasioned by the combination of some of its constituents (including impurities) with atmospheric oxygen, which reactions raise the temperature of the surrounding coal to its ignition point.

Whether this firing is due to the presence of that easily decomposed form of iron pyrites known as marcasite or to the presence of other impurities, it is difficult to say, but we have the strongest evidence—at the large power station referred to—that with the clean coal formerly received, no loss due to spontaneous combustion occurred, but with the dirty coal that is now being received, such firing is almost continuously occurring. Generally speaking, the coals running the highest in non-combustible matter give the greatest trouble due to spontaneous combustion.

As regards the statement that coal containing 40 per cent of refuse is valueless as a fuel, I would say that there is no doubt coal with such a high percentage of refuse will be found to be a very undesirable fuel, but whether it can be burned to produce useful results depends largely upon the rate of combustion, the facilities available to give the fuel bed the requisite air supply, and the skill of the fireman.

It is desirable to know just what is meant by the term "refuse." The word is commonly used to denote the total matter rejected from the furnace, which includes the combustible matter contained in the so-called ash. If it is intended to mean pure ash, or wholly incombustible matter, it is doubtful whether a steam boiler could be operated with such fuel. On the other hand, if it is intended to define the pure ash with accompanying combustible matter, such as is commonly rejected from boiler furnaces, I know that the remaining 60 per cent of fuel has been used successfully for purposes of steam generation.

In the office building in which my office is located they received the so-called steam sizes of anthracite coal last winter and managed to carry their load and maintain the regular steam pressure, burning this coal when taking 42 per cent of refuse out of the ashpit and furnace.

This plant is equipped with five 400-hp. boilers and the ratio of heating to grate surface is 49 to 1. The furnaces are hand-fired, and when burning this dirty coal they maintained a blast pressure of 1¼ in. water pressure under the grates and developed from 70 to 75 per cent of the boilers' rating, as shown by the steam-flow meter.

Much credit is due to the chief engineer of this plant, whose instructions to the firemen made it possible to obtain such remarkable results under adverse conditions.

P. W. Thomas. Our personal experiences with storage coal may be of great interest. All of our coal is of a nature that heats very quickly. Where we are unable to procure underwater storage, we adopt the following plan:

The storage place is first absolutely cleaned of all rubbish in the way of deadwood and vegetation. We then cover the entire area with coal to the depth of about one foot. After this coal has been exposed to the air for one or two days, we place another layer above it. We continue this to a depth of 8 to 10 ft., being careful to store only coal from one given mine. We have carried raw screenings over a period of a year without smolder, where under ordinary circumstances they would have fired in from one to three weeks. A scientific explanation would be rather difficult, but in all likelihood would center around the undoubted fact that each layer so put down has time to lose the majority of its occluded gases and becomes more or less inert. The pyrite also has time to become partially or wholly oxidized.

I note that in Question No. 1 there is a statement regarding the amount of refuse which renders a fuel valueless. I might make the absolute statement that it is not the amount of refuse, but its character. I have successfully burned fuel running 45 per cent ash, but this ash was inert and absorbed no heat from the coal to exceed 3 or 4 per cent. On the other hand, a fuel containing 31 per cent ash, which ash was 90 per cent metallic, failed to carry boiler ratings, although its heating value was over 10,000 B.t.u. per lb. This was due to the fact that approximately 11 per cent of the initial heat in the coal was absorbed by the ash, whereupon it became impossible to maintain a combustion rate that would give sufficient heat to the boiler.

Walter E. Bryan. Where coal is not too small in size and contains few impurities, it can be stored either under roof or in the open for long periods with little danger from combustion and, I believe, little deterioration. We have found it necessary in storing screenings, of rather poor quality, under roof, to allow them to stand not longer than three to four weeks in warm weather. In the open it is almost impossible to store such screenings during the summer months without firing, and with the comparatively poor coal supplied last year it was impossible to store the coal for any great length of time, even in the winter months, without its catching on fire. In my opinion, the question of ventilating storage piles is of questionable value, the important points being not to store too fine coal or dirty coal, and not to store it in large piles.

In case the coal actually does fire, I know of no effective way to put the fire out; it is our practice to pick up the coal as rapidly as possible and use it. I realize, however, that there are several methods of chemically treating the coal after it has fired which are supposed to put the fire out. In the case of coal stored in buildings, care should be taken after emptying a bin that all pockets are brushed out before the new coal is put in.

B. J. Denman. Up to a few years ago I was in charge of plants burning Pennsylvania and West Virginia coking coals which required storage of approximately 100,000 tons. Mine-run coal was stored in continuous piles as high as could be handled by locomotive cranes. No attempt was made to ventilate the piles, and no fires ever occurred. There was no loss in heating value of coal which had been in storage as much as three years.

I am at present storing eastern Kentucky "Elkhorn" gas coal for nine gas plants. Most of this is under cover, but some is unprotected. This coal is stored in piles as high as 25 ft., and no precautions are taken, but no fires have resulted. Most of this coal is ¾-in. lump, but some of it is screenings. Some of the lump coal has been in storage for five years or more.

For electric plants, I am at present storing each winter in various localities from 3000 to 20,000 tons of Illinois and Iowa coal. It is our experience that washed central Illinois coal screenings can be put in stock during the summer and used the following winter with very little danger of firing. Springfield, Ill., district $1\frac{1}{4}$-in. screenings cannot be put in stock in summer without great danger of firing. If this coal is put in stock during the winter time, when the coal is very cold or mixed with snow, it will ordinarily carry through the following summer. Fulton County, Ill., screenings will ordinarily fire before fall if put in stock during the summer months, although we have one plant in northern Iowa where we put about 3000 tons of this coal in stock each year and have very little trouble; in a number of plants in the central part of the state, however, trouble invariably results. This may be due to some climatic condition, but we have not been able to account for it.

We have had very satisfactory results in storing southern Illinois screenings and experience very little trouble. The lump coal from any of the Illinois districts can be carried through the summer without trouble.

Iowa screenings cannot be stored at all during the summer time, and frequently the coal fires in transit. I have had no experience in storing Iowa lump, but am of the opinion that it would disintegrate and fire.

I have had little faith in the usual schemes for ventilating coal piles, and have observed several experiments which have not been satisfactory. It is our practice not to store the coal over 12 ft. high, and if it begins to heat, to move it as quickly as possible.

A. G. Christie. I have found it impossible to store certain grades of western lignite if wet even in as shallow piles as 6 ft. without having spontaneous combustion. Alberta bituminous coal could be stored in piles 12 ft. deep if kept dry. Wet weather may start combustion. We have had no difficulty storing semi-bituminous coal in piles of 12 ft. deep in Baltimore, but care is taken to keep it dry.

Carl Smerling. It is comparatively safe to store bituminous coal containing up to $1\frac{1}{2}$ per cent sulphur in piles not exceeding a depth of 7 to 8 ft. and not be troubled with spontaneous combustion. The same kind of coal can be stored at any depth if supplied with sufficient air pipes penetrating the storage at proper intervals, although we find that in 50 per cent of the cases where bituminous coal is stored, especially through the Middle West, hundreds of tons of coal are lying in the open for years 20 to 30 ft. in depth and containing from 2 to $2\frac{1}{2}$ per cent sulphur. It must be noted, nevertheless, that in all cases spontaneous-combustion fires are found at the bottom of the pile or at the floor level, and it therefore seems advantageous to have from a foot to eighteen inches of water at the bottom of the pile to insure safety.

C. E. Van Bergen. We do not recall any interesting experiences in connection with coal storage, having never had any large quantities to deal with, nor have we had any fires in storage piles. We do not store until fall, and about 1000 tons well spread in piles not over 15 ft. high is the most we ever have on hand.

W. L. Abbott. We have stored hundreds of thousands of tons of bituminous coal every year at a cost not to exceed 10 cents per ton into and out of storage. We have had no trouble whatever in many years with spontaneous combustion in the coal piles. It has been our experience that we can prevent spontaneous combustion by storing grades of coal that do not contain the small sizes, using preferably a 3-in. by 6-in. egg or lump size of coal which has gone over a $1\frac{1}{2}$-in. screen.

12 (a) To What Extent and Where Will the Gas Producer Be Used to Produce Economies?

Robert H. Fernald.[1] There seem to be three obvious fields for producer gas development:

1 For extensive power production at the mines
2 As a substitute for natural gas for general heating purposes
3 In conjunction with by-product coke ovens.

1 In the field of power production through the internal-combustion engine the application of the gas producer seems limited to plants of relatively small capacity. This is due to the fact that the practical size limit for gas engines seems to be not over 5000 hp., and very few engines of this size are built. The gas-engine-gas-producer combination can hardly be considered for central station service. For large power installations the natural development is the by-product producer-gas plant located at the mines in conjunction with steam boilers and steam turbines. The low efficiencies due to the two-step conversion—first, gas generation from the coal and, second, burning of the gas under steam boilers—may be counterbalanced by the development of highly efficient boilers equipped for gas burning, and by the return from the valuable by-products secured from the coal. Should the development of the gas turbine result in commercial units that compare favorably with the present large steam turbine units, additional marked economies may of course be looked for.

2 The depletion of the supply of natural gas in many regions is leading to the gradual substitution of producer gas in place of natural gas,—using producers of either the by-product or non-by-product type.

3 This field embraces two divisions; (*a*) one in which there is an unlimited demand for the coke from the ovens as well as for the gas and by-products; (*b*) one in which there is no market for the coke but a ready market for the gas and by-products.

a This type of plant is composed essentially of two distinct installations, a by-product coke plant and a by-product producer gas plant. The entire gas output of the coke plant may thus be made available for the market, as the lower heat value producer gas may be used for heating the coke ovens. One of the advantages of this system lies in the fact that coke breeze and low-grade fuels may be used in the producers. In a large European plant of this type the coke oven gas is the main product and the coke, which finds a ready market, is regarded as one of the by-products. The by-products from the producer-gas plant, sulphate of ammonia and pitch, practically pay the cost of operation of this portion of the installation.

[1] Professor of Dynamical Engineering, University of Pennsylvania, Philadelphia. Mem.Am.Soc.M.E.

b In case there is a demand for the by-product coke oven gas but no convenient market for the coke, the natural step involves placing gas producers in close contact with the by-product coke plant, feeding the coke directly into these producers. Such portion of the producer gas as is not used for heating the coke can be mixed with the by-product coke oven gas for general distribution.

Developments along the three lines indicated seem to offer attractive possibilities, and their adoption on an extensive scale would lead to economy in fuel consumption.

12 (b) To What Extent Is Natural Gas Being Used as a Fuel for Power Purposes?

SAMUEL S. WYER.[1] The natural gas industry is in a transition stage, changing from the large-volume, low-price-per-unit basis, to the relatively small-volume and larger-price-per-unit basis. The reasons why natural gas cannot and ought not to have an extensive use for steam-boiler work in the future may be enumerated as follows:

a The number of domestic consumers, now over 2,363,000, is increasing much faster than the number of producing wells

b The initial production and the routine available production coming in are much lower than for wells that came in five years ago. This is due to the general depletion of existing fields, and the extensive underground drainage from past production

c New fields are not being discovered fast enough to replace the rapidly declining present supplies

d The general shortage of coal for domestic heating in the past and the inevitable continuance of this condition for some time in the future, at least during the period of the war, has placed enormous additional demands for domestic heating on the natural-gas resources where natural gas is now and will be used in lieu of solid fuels for heating homes.

Natural gas is preëminently a domestic fuel. Its high heating value, practically twice that of any manufactured gas available, its purity, and ease in handling make it the premier fuel for home use. While low-grade solid fuels can be efficiently used under steam boilers with proper stoking equipment, they cannot be satisfactorily or efficiently used for house heating. For this reason it is a matter of conservation to use the fuel for domestic service that in the long run will yield the greatest good to the greatest number.

The tests recently made in the Home Economics Department of the Ohio State University on cooking various meals with natural gas, soft coal, coal oil, gasoline and electricity, show conclusively that natural gas is by far the cheapest fuel for the domestic consumer's use for cooking. Thus, in cooking a dinner for six people, the total fuel costs, with natural gas at 40 cents per 1000 cu. ft., soft coal at $6.50 per ton, coal oil at 15 cents per gallon, gasoline at 27 cents per gallon, and electricity at 3 cents per kw-hr., were substantially as follows:

Natural gas	0.88 cents	Electricity	5.0 cents
Soft coal	2.5 cents	Coal oil	5.4 cents
Gasoline	4.6 cents		

The rendering of domestic natural-gas service is a public-utility business. Practically all of the states where natural gas is now produced and sold have public-utility commissions with broad powers in matters of rate regulation and quality of service. The general tendency, and the one that is in accordance with sound public policy, is to give the domestic consumer first preference and curtail the consumption of natural gas for industrial purposes. For the reasons given in the preceding paragraphs, it may be reasonably expected that this tendency will become more marked in the future and public-utility regulations regarding the use of this best of all of nature's fuels for domestic service will become more exacting and ultimately will result in the very great curtailment of the use of natural gas for steam-boiler work and for other industrial purposes.

12 (c) What Is the Relative Economy of the Locomotive of 1900 and Today?

JOHN E. MUHLFELD. The general development of the steam locomotives in use in the United States since 1900 can be best shown by the data in Table 11, which are approximately correct.

SUMMARY OF ECONOMIC FEATURES

Prior to 1900 considerable development work had been done on two-, three- and four-cylinder types of compound locomotives by Mallet, Webb, Pitkin, Mellin, Vauclain and others. Pitkin's two-cylinder system was applied to a Michigan Central 10-wheel locomotive in 1889, and Vauclain's four-cylinder system was first introduced on a Baltimore and Ohio 8-wheel locomotive—No. 848—in October of the same year. These and other developments caused the adoption of both the two- and four-cylinder systems in new locomotives, the maximum application being reached during 1904, when approximately 1,000 two-cylinder, and 2,000 four-cylinder compound locomotives were in existence.

Previous to 1900 Schmidt, Pielock and others had done considerable experimenting with superheated steam, the former having succeeded in 1894 in producing a boiler and motor in which superheated steam of relatively low pressure was used at about 700 deg. fahr.

The failure of the compound locomotive to produce the economy predicted—due largely to the factors of indifferent design, lack of proper maintenance and operation, cheap fuel and road failures—resulted in the general return to the single-expansion cylinder locomotive, and this, with the demand for greater steaming capacity per sq. ft. of boiler heating surface, naturally brought about consideration of the use of superheated steam. The results of further experiments by Vauclain,

[1] Consulting Engineer, Columbus, O. Mem.Am.Soc.M.E.

Vaughn, Horsey, Cole, Emerson, Jacobs and others, along the lines of high and low degrees of superheat, in combination with either high or low steam pressures, by means of smoke-box, fire tube, or a combination of both types of superheaters.

TABLE 11 STEAM LOCOMOTIVES IN THE UNITED STATES SINCE 1900

Year	Item	Single-expansion cylinder	Two-cylinder compound	Four-cylinder compound	Mallet articulated compound	Total locomotives
1900	Number	36,600	1,000	900	..	38,500
	Average tractive power, lb	19,000	28,000	29,000	.	..
	Average wt. on drivers, lb.	85,000	125,000	130,000	..	..
1905	Number[1]	48,949	900	1,800	1	51,650
	Average tractive power, lb.	23,000	31,000	32,000	75,000	..
	Average wt. on drivers, lb.	100,000	140,000	145,000	335,000	..
1910	Number[2]	56,425	875	1,500	200	59,000
	Average tractive power, lb.	27,000	31,500	40,000	72,000	..
	Average wt. on drivers, lb.	120,000	142,000	175,000	320,000	.
1915	Number[3]	62,000	650	1,300	800	64,750
	Average tractive power, lb.	30,500	32,000	33,000	79,000	.
	Average wt. on drivers, lb.	135,000	145,000	148,000	350,000

[2] Includes 300 superheater and 3000 oil-burning locomotives.
[3] Includes 14,000 superheater aod 4250 oil-burning locomotives.

resulted in the fire-tube type being now practically a standard part of all new equipment, and it is further being rapidly applied to existing saturated-steam locomotives in the United States.

While the Cole and Vauclain balanced compound types of locomotives as brought out since 1900—along the lines of the French De Glehn system—have not made much progress, the Mallet Articulated Compound system, introduced on the Baltimore and Ohio in 1904, is now in use on over fifty railways in the United States, and aggregates more than 1,500 locomotives. This latter type of locomotive not only permits extreme concentration of great power over a flexible wheel base within axle-load limits, but also reduces the stresses by greater distribution and lightness of parts, and through the combination of high-pressure superheating, compounding, simpling and reduction of unbalanced pressure gives the maximum direct and reserve tractive power for from 25 to 35 per cent less fuel and water consumption per ton-mile than a superheated single-expansion locomotive.

Comparison of Steam and Electric Equipment for Railways

With regard to the present status of the relative economy of steam and electric locomotives in the United States, as compared with the results obtained in 1900, general conditions have very substantially changed and the predominating factors today are manual labor and fuel for operation. While the inauguration of the use of fuel oil on almost 4500 steam locomotives has somewhat improved the firing and steam-generation conditions, the increasing cost and demand for oil for more essential purposes and the reducing supply will soon make its use for locomotive fuel prohibitive. However, the use of oil as a locomotive fuel has long since demonstrated that the mechanical feeding and burning of fuel in suspension, whether gaseous, liquid or solid, for the production of steam in a self-contained motive-power unit, is the most logical, successful, effective and economical method for generating power and moving long-haul heavy-tonnage traffic on railways.

Even where hydroelectric power is available the self-contained steam-power-plant locomotive will show a much lower cost for fixed charge, maintenance and operation than the electric unit, as the transmission and conversion of electric current into drawbar hauling capacity is a very wasteful and expensive process in the present state of the electrical art. In fact, the principal economies brought about in the electrical field during the past quarter century have been in the production and use of steam for the generation of current and not in the electrical apparatus.

As applied to a long-haul railway, the metering and conveying of extremely high-voltage current from various power-plant sources into transmission mains, through switching sub-stations, transforming and converting, conveying to contact lines and converting into great hauling capacity at the drawbar results in enormous line and bonding dead losses, which will bring the cost of even hydroelectric current per drawbar horsepower hour to from 6 to 7 mills. This cost, which, in combination with copper limitations, fixed train speeds up and down grades, general tie-up of operation in case of failure, and like factors, will hardly admit of comparison with steam-locomotive boilers operating at equivalent to 700 per cent of the rated capacity of stationary boilers, with a 75 per cent combined furnace, boiler and superheater efficiency, and furnishing a boiler horsepower for each $1\frac{1}{2}$ sq. ft. of evaporating surface and producing a drawbar horsepower-hour for $2\frac{1}{4}$ lb. of coal.

Improvements to be Expected in Steam Locomotives

Nevertheless, the steam locomotive is still in its infancy so far as economy per ton-mile is concerned. The atomization and burning of liquid or solid fuels in suspension will enable the elimination of grates and other metal work from the combustion zone and permit of higher furnace temperatures and more complete and effective combustion, which, in combination with higher steam pressures; compounding; higher superheating of both high- and low-pressure steam; utilization of waste gases and steam for feedwater heating and purification; better boiler-water circulation; reduced cylinder clearances and back pressure; improved steam distribution; lower factor of adhesion; higher percentage of propelling to total weight; less radiation; elimination of unbalanced pressures and weights; application of safety and labor-saving devices, and the greater refinement and perfection of general and detailed design, equipment and control throughout, will yet enable it to produce a drawbar horsepower-hour for one pound of coal.

Steam-Electric Locomotives

Furthermore, it is not inconsistent to now predict that a self-contained steam-electric articulated compound locomotive, combining the advantages of both steam and electric motive power, will shortly find a useful field in services where maximum power and efficiency at high speeds; greater utilization of existing waste heat; high starting and low speed torque and rapid acceleration are required and where an exclusive electrification system would not be permissible from the standpoint of first cost or justified on account of the combined expense for operation and maintenance.

12 (d) What Is the Proportion of Coke Made in By-Product Ovens in the United States?

C. E. Lesher.[1] The proportion of coke (excluding gas-house coke), made in by-product ovens in the United States has increased from 17.1 per cent in 1910 to 40 per cent in 1917. The figures, by years, are as follows:

Year	1910	1911	1912	1913	1914	1915	1916	1917
Per cent	17.1	22.1	25.3	27.5	32.5	33.8	35.0	40.0 (Est.)

The development of the by-product coke industry in the United States up to the close of 1914 was largely the result of the recognition by iron and steel companies of the economies possible by the recovery of by-products and of the flexibility of operation, as well as the assurance of a regular and continual supply of suitable blast-furnace fuel.

Beginning in 1915, and most strikingly so today, the necessity for benzol and toluol for explosives and chemical manufacture has given this industry marked impetus. So urgent are the demands for explosives that the Federal Government is expected to finance the erection of additional by-product ovens this year.

These new by-product plants will continue to be operated after the demand for coke—now abnormal—decreases, with the result that the percentage of by-product coke to the total output in the United States will continue steadily to increase.

W. H. Blauvelt.[1] Preliminary Government estimates place the total coke production for 1917 at 56,600,000 tons, the largest tonnage in the history of the industry. Of this production, 34,000,000 tons, or 60 per cent, was beehive coke, and 22,600,000 tons, or 40 per cent, was by-product coke.

The by-product plants now under construction in the United States will have a capacity of 13,800,000 tons. Not all of these plants now building will be put in operation this year, but the majority of them will, so it seems safe to prophesy that at some time the latter part of this year the production of by-product coke will pass the beehive production. The total capacity of the by-product ovens in the United States now in operation or under construction will be about 40,600,000 tons per annum. This is more than 5,000,000 tons above the maximum production of the beehive industry in 1916, when all of the conditions were favorable to bringing out the greatest possible production from the beehive plants.

12 (e) What Are New and Important Developments in Methods of Burning Coal?

W. W. Jourdin.[2] Aside from cost, the advantages of fuel oil in steam-boiler practice over rough-crushed coal are so manifest that a particularly strong inducement exists at this time of increasing power costs to apply the economic test to coal in this form.

The superior thermal efficiency of gaseous fuels is unquestionable, but commercial success in the manufacture of gas for firing under boilers has not been realized. Coal, when ground so fine that 95 per cent will pass 100 mesh, can be conveyed through pipes over considerable distances as readily, almost, as oil, and combustion will occur in a manner quite analogous to that of gas, provided air be supplied in proper proportion and in intimate contact with the particles of the coal.

That desirable characteristic of oil—easy and complete control of the heating medium to meet variations in steam demand—is inherent to coal in this finely divided state. Better economy is attainable than with coal as commonly fired, since excess air may be kept within narrow limits, and, furthermore, the boiler room is free from heavy storage and handling equipment.

This feature of quick response to variable load conditions cannot be fully appreciated by one whose experience has been confined to stoker equipment. In the plant with which the writer is connected, the excess air is usually maintained within 10 or 12 per cent of theoretical requirements, and with a 50 per cent variation either way from normal load the automatic regulating system will respond so quickly that the extreme variation in steam pressure will be not more than 2 lb. per sq. in., equivalent to 1 per cent of normal. When properly adjusted the damper regulator opens the dampers in time to prevent smoking, in the case of an increase in the rate of firing, or a "clear stack" with a sharp reduction of load.

Steam is the best atomizing agent for oil, but compressed air appears to be most satisfactory for use with powdered coal. All air required for combustion may be compressed by turbo-blowers to a comparatively low pressure, heated by the waste gases, then released in a mixing chamber or burner designed to distribute the charge evenly in the furnace.

The methods used to atomize pulverized coal fall short of requirements since the evaporative efficiency is generally lower, often up to 10 per cent, than obtained with gas or oil. With well-designed apparatus, however, nearly constant oxygen-carbon ratio should obtain over a wide range, and evaporative efficiency need not be less than is developed in the best oil-burning practice.

The grinding and drying equipment should be placed between the boiler plant and coal in storage. The quantity of waste gases to be diverted to the drying plant will depend upon their temperature and the moisture content of the coal. The best performance known to the writer is 4 to 5 lb. of water evaporated per pound of coal used in the dryer; in certain plants the ratio is nearer unity. Therefore, with coals running high in moisture a material saving will be possible by the use of waste gases in the dryer.

A large pulverized-coal plant is being installed in Seattle, where oil is cheap compared to places more remote from the oil fields. If we cannot afford to burn oil, let us weigh carefully the possibility of utilizing this fine substitute.

12 (f) What Economies Have Resulted from Recent Practice in Making Brick Settings Leakless?

Albert A. Cary. The remarkably low flue-gas temperatures frequently reported from boiler tests are generally due to air leakage through boiler settings or at flue connections. A number of boiler tests which I have made were conducted in such a manner as to determine these losses and I will therefore give the results of three or four of these tests from which can be appreciated the gain in efficiency that would result if the air leakage were suppressed.

1 Two horizontal tubular boilers of the same size and located in the same plant, with settings supposed to be identical, gave the following results by taking samples of gas simultaneously from the rear end of the furnace chamber and just inside the flue outlet:

	Boiler *A*	Boiler *B*
Excess of air found in the furnace..	70 per cent	49 per cent
Excess of air found at the flue outlet.	103 per cent	71 per cent

These results clearly show how worthless the gas analysis taken at the flue outlet really is, as an indication of the conditions of combustion in the furnace.

Turning now to temperature readings taken just inside of the flue outlet, a nitrogen-filled thermometer, with proper corrections applied, showed that the temperatures of gases escaping from the boiler settings were as follows:

Boiler *A*	Boiler *B*
543 deg. fahr.	482 deg. fahr.

By making corrections for the chilling effect of the infiltrating air, we find that had there been no air leakage through the boiler settings, the temperature of these escaping gases would have shown, with Boiler *A*, 607 deg. fahr., and with Boiler *B*, 562 deg. fahr.

The actual loss in efficiency due to air leakage in these two boilers was as follows: Boiler *A*, 1.73 per cent; Boiler *B*, 2.13 per cent.

The losses occurring in these cases principally were due to the chilling effect of the cold entering air alone, as it was found that practically all of the air leakage occurred beyond the furnace and combustion chambers. A correction of the gas analysis taken at the flue outlet, making allowance for the increased air supply, shows practically the same results as were obtained in the samples of gas taken from the combustion chamber.

2 I will next refer to two interesting tests made with a water-tube boiler having its heating surface widely distributed, and requiring a setting about double the size of a normal setting. It was equipped with stationary grates and hand-fired. One test was conducted at the rated capacity of the boiler, while the second was a forcing test.

During the non-forcing test, I found that the average excess air in the *furnace* was 45.05 per cent, while the excess air found in the escaping gases, just inside of the flue outlet, was 95.79 per cent. There was an unusually high loss in the combined efficiency of the boiler and furnace operation due to air leakage through the masonry; namely, 4.63 per cent.

The average combustion, during this test, was 20.87 lb. of dry coal per sq. ft. of grate.

During a subsequent forcing test, when 40.15 lb. of dry coal was burned per sq. ft. of grate under forced blast, the entire chamber enclosing the boiler was under pressure so that the furnace gases actually blew out through cracks in the masonry and thus we had a case of gas leakage outward.

There is no necessity for employing extraordinary means to obtain tight boiler settings. Long experience has taught me that the material we have been employing for years, if properly selected and properly erected in place, will produce a setting that for all practical purposes is tight and can easily be made to remain tight for years.

It is the duty of every engineer who is called upon to install boiler settings to study the stresses and strains that occur in boiler masonry the same as he is supposed to do in other designing work and he must also study the widely varying qualities of the various materials used so as to make and secure a proper selection. Extreme expansion and contraction are constantly occurring in nearly every part of a boiler setting and they must be properly provided for. The interior of a furnace wall may be subjected to a temperature of 2000 deg. and running upwards to nearly 3000 deg. fahr., while its exterior is sometimes subjected to a freezing temperature.

What can we expect but disintegration, cracking or distortion, if provision is not made to meet these conditions? With bridge walls or arches heated to very high temperatures and expanding against the side walls, how can we expect such walls to withstand such pressures without cracking unless provision is made to relieve or prevent such thrusts by proper arrangement of supporting beams, buck stays, pockets in masonry, or other means properly applied?

The average mason knows little or nothing about laying up firebrick work and bonding it properly into the red-brick exterior, and yet this most important matter is often left to such men. I always make it a practice to specify exactly how this work should be done.

The market is filled with most undesirable material for boiler setting and if proper refractory material, red brick, mortar, fireclay or high temperature cement is not distinctly specified, the poor client simply buys his trouble and adds to his maintenance account, when he has such unsuitable material dumped into his boiler setting.

Proper provisions must be made for relining furnace interiors without damaging other parts of the setting. Provision must be made for supporting the boiler securely and for taking care of the expansion and contraction of the boiler itself and the greatest care must be exercised to provide ample foundations which will not settle.

12 (h) Is Automatic Air Supply Correctly Proportioned to Coal Supply Possible?

M. C. M. Hatch. Theoretically, such control of the supply of air necessary for combustion would seem to be desirable. There is a certain amount of excess air which, for a given furnace design, method of firing and nature of fuel, will give

the best results, and this excess, expressed as *percentage*, will be constant throughout the entire range of fuel rates, from lowest to highest.

Accurate control of the air for any method of burning coal on grates, either by hand or by stoker firing, is more or less difficult and may be, and probably is, impossible under many conditions. The comparative sluggishness of furnace action with coal thus fired to respond to rapid variation in load on the boiler and the fact that grates will clinker or ash over, changing the air-inlet area under the fire, account in large measure for the difficulties encountered, and these faults would seem to be inherent in grate firing.

Coal burned in pulverized form offers a chance for development work along the line of positive air control. There is no change of air-inlet area to the furnace caused, automatically, by slagging or ash deposits. The excess air necessary can be readily determined and is materially less, on account of intimate mixture, than in other methods of burning coal, hence, for a given fuel rate, the total amount of air to be controlled is reduced. The flexibility of the furnace, by which is meant its ability to respond almost instantaneously to varying demands upon the boiler, is very pronounced, and this again simplifies the problem.

Pulverized coal, fed by carefully-designed screws which give practically constant delivery per unit revolution for all feeds, affords ideal conditions for standardization work in furnace operation. It is entirely possible, although there has as yet been no attempt made to place such an arrangement on a commercial basis, that the position of the main boiler damper and of the dampers in the induced-air pipes may be synchronized with the feed-screw revolutions in such a way as to insure constant air-excess percentage at all furnace outputs.

12 (l) Miscellaneous—School Heating, Insulation, Smoke Prevention

J. H. Brady[1] contributes a report made by him to the Board of Directors of the School District of Kansas City, Mo. This report is given in great detail and is extremely valuable. It contains a tabulated statement for 1916-17, showing the cost per cubic foot for heating the buildings of the school district.

There are 88 public buildings having a total cubic contents of 32,300,000 cu. ft. and an average per building of 367,000 cu. ft. More than half the buildings contain over 250,000 cu. ft. of space and several are much larger. The cost of fuel for all the buildings averaged 3.1 mills per cu. ft. The figures given in the report include the fuel furnished the custodians of the buildings for their residences, except in the case of seven buildings. In what follows is a brief summary of the conclusions:

Grouping the buildings according to the type of heating plant used gives the following results:

Group No. 1, steam hot blast, using fuel oil, average cost 3.5 mills per cu. ft.

Group No. 2, direct radiation, using fuel oil, average cost 3.6 mills per cu. ft.

Group No. 3, steam hot blast, using coal for fuel, average cost 2.8 mills per cu. ft.

Group No. 4, direct radiation, using coal, average cost 2.9 mills per cu. ft.

Group No. 5, frame and brick buildings heated by stoves, average cost 4.1 mills per cu. ft.

Group No. 6, schools heated by hot-air furnaces, using coal, average cost 3.6 mills per cu. ft.

Contrasting two of the buildings, the writer states:

"Central High School shows a cost of 2.7 mills per cu. ft. while Northeast shows a cost of 2.5 mills per cu. ft. The cubic contents of Northeast High is greater than Central High, and the difference in the cost per cu. ft. for heating the two buildings is, in my opinion, due to the fact that Central High has metal frames and sash while Northeast has wooden frames and sash, and the leakage of air or wind around metal sash is greater than with wooden sash. Both these buildings use coal for fuel. As a rule the high cost of heating certain buildings is caused by metal frames and sash, while in other buildings it is due to poor construction, taking into account their age, etc."

Another point is the fact that where mechanical ventilation, or what is known as hot blast fan system, using coal for fuel, is installed, the cost for heating per cu. ft., is less on an average than the others, being 2.8 mills.

The fact that the figures for schools equipped with mechanical ventilation run less than for those not so equipped may be attributed to automatic temperature control. The highest cost per cu. ft. is shown where stoves are used for heating, being 4.1 mills.

[1] Chief Engineer and Supt. of Buildings, The School District of Kansas City, Mo. Mem. Am.Soc.M.E.

G. D. Bagley.[1] The insulation of heated surfaces to conserve radiation and convection losses often does not receive the attention which it deserves. Such insulation is necessary regardless of the purpose of the installation or the method of heating. Coverings of the proper thickness and material applied to power plants, chemical plants, heating systems, etc., result in a large saving in coal and a high rate of return on the investment.

The losses from such surfaces range from 2 to 10 B.t.u. per sq. ft. per hour per deg. fahr. temperature difference, at the temperatures at which steam is used and amount to 300 tons of coal per year for every 1000 sq. ft. of exposed surface at 100 lb. steam pressure.

The Mellon Institute of Industrial Research has been engaged for some time in making a study of heat insulating materials for the Magnesia Association of America, and in order to check up the results of the laboratory work under practical conditions a set of tests was made on a boiler before and after covering with magnesia.

The tests were made at a mine at Bruceton, Pa., in conjunction with the Bureau of Smoke Regulation of the City of Pittsburgh. The two boilers used in the tests were of the locomotive type, 60 and 80 hp., fire tubes and single pass. They were installed on concrete piers without coverings. The total uncovered surface was 675 sq. ft. and the average pressure 80 lb. per sq. in.

Each test covered a period of 24 hours. The firing was under the supervision of the Bureau of Smoke Regulation in order to have it as consistent and regular as possible. The coking method was used, firing the coal in the front of the furnace, leaving the fire door open for a short time after each firing, and breaking the coal back as it coked. This method of

[1] Mellon Institute, Pittsburgh, Pa.

procedure resulted in nearly smokeless combustion of the fuel.

During the first test, 10,784 lb. of coal were used and 58,000 lb. of water were evaporated. This corresponds to a rate of 6.35 lb. of water from and at 212 deg. fahr. per lb. of coal as fired.

After the first test was completed, the boiler was covered with 1½ in. of magnesia blocks, and plastered with magnesia cement and a coat of hard-finish cement for protection, making a total thickness of about 2 in. The boiler test was then repeated, taking great care to hold the load at the same values as during the first test, and to keep all other conditions the same.

In the second test, 59,500 lb. of water were evaporated and 9296 lb. of coal consumed, giving a rate of 7.55 lb. of water from and at 212 deg. fahr. per lb. of coal as fired and a saving of 1488 lb. of coal per day.

If calculated for an equal water evaporation, the saving would be 1700 lb. of coal. It seemed much easier to hold a nearly uniform pressure after the boilers were covered and this probably accounts for the excess of the measured saving over that calculated, as the coal was burned more uniformly and the boiler efficiency was higher.

The saving in coal as shown by this test amounted to about 15 per cent of the coal originally burned. The per cent saving will vary with the amount of exposed surfaces in proportion to the capacity of the boilers. The losses shown by the test are those due to heat loss from the boiler alone and do not take into account the losses from the pipe lines which cause condensation and wet steam in addition to wasting coal.

The tests show that the losses from uninsulated surfaces are large enough to amount to a very considerable factor in the total coal consumption of the country, and to warrant every one who is interested in the conservation of fuel in seeing that all surfaces, however small, are properly insulated.

Victor J. Azbe. In regard to smoke prevention, if we would base our studies upon furnace volume, gas velocity, composition of volatile matter, and take into consideration eddies and whirls, dead space, etc., we soon would have information enough collected to design furnaces for any type boiler and any fuel so smoke would not be produced. That most furnaces are built upon unscientific principles can be shown by a study of gas flow with a fairly accurate anemometer in a cold boiler when the damper is open.

PROGRESS REPORT OF COMMITTEE ON LIMITS AND TOLERANCES IN SCREW THREAD FITS

To the Council of The American Society of Mechanical Engineers:

The Committee on Limits and Tolerances in Screw Thread Fits was assigned by the Council of The American Society of Mechanical Engineers the task "to prescribe the permissible tolerances in the commercial manufacture of taps, dies, bolts, nuts, and screws, including the method of measuring of the same."

During the years following the appointment of this committee, many meetings have been held, and work has been done through sub-committees, involving a great amount of investigation and study.

Methods of Investigation

Careful study has been given to data already published and assistance has been secured from the U. S. Bureau of Standards, The Franklin Institute, the Navy Department, and from other sources.

A request sent to many tap makers for confidential information showing the limits allowed for their commercial work, led to a response by a number of leading manufacturers, giving such information. This was tabulated and compared. Later, some of the tap makers assisted by having over 4000 taps of commercial sizes from $\frac{1}{4}$ in. to 2 in., secured from a number of different makers, measured for errors in lead, in order to obtain the average variation of commercial taps which are in use today.

Early in the investigation, a meeting of screw manufacturers and users was called at the headquarters of The American Society of Mechanical Engineers in New York, at which about forty representatives were present, and the matter of tolerances and limits in screws was thoroughly discussed in the light of a tentative report which this committee had prepared. This meeting resulted in the appointment of a sub-committee, consisting of Messrs. E. H. Ehrman of the Chicago Screw Company, E. A. Darling of the Draper Company, and C. B. Young, engineer of tests of the Pennsylvania Railroad Company, to coöperate with the general committee by obtaining data from the screw manufacturers.

Through this committee, and the officers of the A.S.M.E., over 5000 screws were obtained from the regular commercial stock of many different manufacturers, these representing work of various grades and sizes, and with cut and rolled threads. These screws were measured and the results tabulated.

Sample screws and nuts were prepared having varying degrees of error in diameter and lead, and from these it was determined what would be the maximum error allowable, and charts were made to show the relation of taps and screws measured to these allowable limits.

Sample gages were also made to a closer limit than those now proposed by the committee, in order to learn how close it was practicable to make commercial work. These gages were distributed without stating what the allowance was in order that the users might not be prejudiced by thinking the limits were closer than they could work to.

Comparisons have also been made with the allowances and tolerances recommended by the British Engineering Standards Committee.

The recommendations of the report are the outcome of all this study and investigation.

While separate diagrams have not been provided for manufacturers' standards and users' or consumers' standards, it is expected that manufacturers will aim to work within the zones established by the diagrams so as to produce work that will come within these limits; and that gages will be so made as to insure this result.

Allowances to be provided for are wear of tools and unavoidable imperfection of workmanship.

Gaging Systems

The gaging tools required *for the threaded hole* are:

- *a* Threaded "go" plug of a length equal to the longest engagement of work
- *b* Threaded "not go" plug, made short and with clearance for full and root diameters;

and *for bolt or screw:*

- *a* Threaded "go" ring of a length equal to the longest engagement of work
- *b* Threaded "not go" ring made short and with clearance for full and root diameters.

The study given to gaging systems has led to the conclusion that no one system is best adapted to all needs; and that for a variety of work made in moderate quantities a gage for measuring errors of diameter and lead combined in the same instrument may give the best results, while for manufacturing in large quantities a fixed gage for one size only and having separate means for measuring errors in diameter and lead may be best.

There is also the need in many cases of master gages, inspection gages and workman's gages, each so made as to suit the particular needs.

A number of designs of gages for these various purposes have been submitted to 40 prominent manufacturers and users, and following their recommendations selections have been made which are illustrated and described in this report.[1]

The illustrations, Figs. 9 to 17, give general suggestions only of what it is recommended to use as it would require too voluminous a report to fully cover the ground.

Tables for Limits and Tolerances

It is believed that eventually three grades should be established, to cover not only general work, such as is here provided, but also that of more restricted and more liberal tolerances. This report deals with limits and tolerances for general work only.

Tables covering medium-grade work for general use have been prepared for diameters from $\frac{1}{4}$ in. to 2 in. but the formulæ can be used for sizes beyond this range. They can also be used for different numbers of threads for a given diameter within ordinary range, provided the thread is of the U. S. S. form.

The variations which affect the fit between screw and nut

Received by the Council, February 15, 1918, and ordered printed. Presented at the Spring Meeting, Worcester, Mass., June 1918, of The American Society of Mechanical Engineers. All papers are subject to revision.

[1] Reference can also be made to Report No. 38 on British Standards for Limit Gages for Screw Threads.

are those of diameter, lead, including length of engaged thread, and angle of thread, besides others of a minor character, such as the crookedness of tap, the condition of its cutting edge, the kind of metal being tapped, etc. The first three of these variations have been definitely taken into consideration in the tables included in this report, and it is believed that the allowance is sufficient to provide also for the other variations mentioned, unless they are extreme.

The effect of errors of lead on the quality of fit is proportional to the length of fit; but the effect of this is modified by the error in pitch diameter. Thus, if a tap, for example, is materially oversize, it can have a greater error of lead than would be the case if it were nearer to the standard size, and

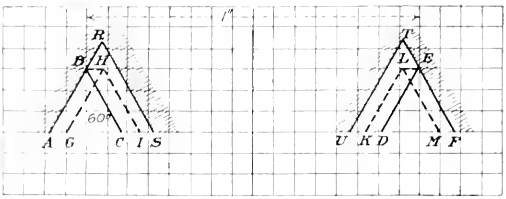

FIG. 1 EFFECT OF VARIATION IN LEAD

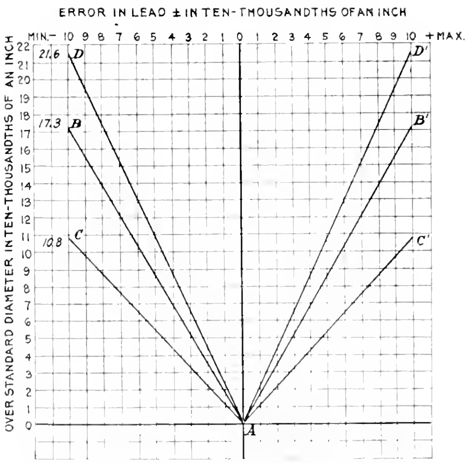

FIG. 2 EFFECT OF VARIATION IN LENGTH OF FIT BETWEEN SCREW AND NUT

still give satisfactory results in use, because the error in lead counteracts the increased diameter of the tapped hole to an extent dependent on the length of fit in the tapped hole.

The available variations, when the length of fit is not in excess of one diameter, are shown by the triangular zones of Tables 1 to 18. They are such that any screw having a diameter and error of lead which would come within such zones would enter any tapped hole which would also pass like inspection in the zone established for holes; and the extremes which would pass inspection as to looseness would not be so loose but that they would be considered mechanically satisfactory for general work.

The zones in Tables 1 to 18, as has been stated, are based on the engagement between screw and tapped hole with a length of fit equal to one diameter. If the length of fit is greater than one diameter there is a possibility of interference in *extreme cases* such as where a screw having the longest allowable lead is screwed into a hole of a depth greater than one diameter of screw, which has been tapped with a tap having the shortest allowable lead.

Under these conditions, however, unless the length considerably exceeds $1\frac{1}{2}$ diameters of the screw, the flow or distortion of metal when forced by the wrench will allow the parts to be screwed together. Actual tests made under the direction of the committee show this to be so. After the first engagement, where the fit might seem unduly tight it would be materially easier,—in fact, for many uses it would be better than a shaky fit even if within the prescribed limits.

For this reason it is believed that taps, nuts and screws passing inspection within these limits, even where it is not known what length of thread may be required in actual use, can be used with the expectation that the work will be interchangeable even when the length of engagement is greater than one diameter, although theoretically there might be the interference in lead above pointed out. The keeping within the prescribed limits would be a radical improvement over the variations of taps and screws in general use today, because of a common standard serving as a "bull's-eye" at which all would aim.

If in any case it should be important to entirely avoid interference in lead, the narrower zones shown by the triangles for the larger-sized screws having a length equal to the length of fit between screw and nut to be used, will show the limiting zone. This method can be used in any case where greater accuracy is desired, and is further explained in the last three paragraphs under the heading How to Use the Tables. The plan here submitted is based on having the maximum screws basic in pitch, outside and root diameters.

Generally stated, all tapped holes should be above basic standard and all screws, below; the more above or below in pitch diameter the greater the allowance possible in error of lead, while still maintaining a satisfactory fit.

In Tables 1 to 18 the figures for taps are held to a limit slightly above the largest allowable screws to provide for wear of the tap, the greatest allowance being made at perfect lead where a reduction in diameter due to wear would be most objectionable. In applying the tables and diagrams to the use of fixed gages, a rectangle representing a given maximum and minimum in pitch diameter and a given error in lead within the triangular zone can be established. Work failing to pass inspection with such gages can be then measured for diameter and lead, and if coming within the triangular zone even though outside the limits of the gages need not be thrown out but can be accepted for use.

CHARTS AND TABLES FOR LIMITS AND TOLERANCES SHOWN IN TABLES 1 TO 18, INCLUSIVE

When a screw or nut has an error in lead, the amount of that error varies directly as the length of thread on screw or depth of threaded hole, i.e., the longer the screw or the deeper the hole, the greater the total error in lead; and where a definite quality of fit between a screw and nut is desired, less error in lead per inch can be allowed for a long thread than for a short one.

In these tables and charts, therefore, the length of thread is made the governing feature and any chart applies equally well to a screw or nut of any diameter or pitch, for the length of thread specified.

The limits for the lengths of threads as adopted and shown

by the charts are 0 for the minimum limit and once the nominal diameter of U. S. S. thread for the maximum limit. In this way each chart is especially applicable to a definite size and becomes a standard for that size between the lengths of thread specified.

Another factor in the fit between a screw and nut is the pitch diameter measured on the "V" of the thread. For a 60-deg. thread of a *given length* the error in pitch diameter bears a definite relation to the error in lead.

This is illustrated in Fig. 1 where *ABC* and *DEF* represent two threads 1 in. apart on a standard thread gage. Let *GHI* and *KLM* represent two actual spaces cut by a tap of the same pitch diameter with an error in lead equal to *BH* and *LE*. Then the stock *ABHG* and *LMEF* would interfere with the entrance of the threaded gage. But if the tap was increased in radius by the amount *RH*, its lead remaining the same, then it would cut the spaces *ARS* and *UTF* and the thread gage would enter full length and bear along the surfaces *AB* and *FE*.

From this it follows that to obtain a fit for a definite length of thread the pitch diameter can be made to compensate for any error in lead within reasonable limits.

This relation between the pitch diameter and lead, when *plotted* on the chart, becomes a straight line.

In Fig. 2 a tap or screw with perfect lead and pitch diameter would fall at the intersection of the two zero lines at *A* and, we will assume, would cut a perfect thread for a threaded hole 1 in. deep, i.e., a hole in which a standard threaded plug gage would fit.

Another tap having an error in lead of 0.0010 in. per inch

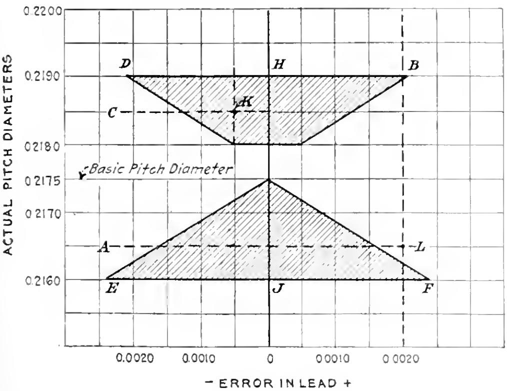

Fig. 3 Diagram Illustrating Method of Using Charts Shown in Tables 1 to 18

but having an increased pitch diameter of 0.00173 in. would fall at *B'* and for a hole 1 in. deep would be the equivalent of the first tap. If two nuts 1 in. thick were tapped one with each of these taps, a standard threaded plug gage when clear through the nut would fit with equal shake in both nuts.

The line *AB'* passing through zero represents *all* oversize threads 1 in. long with a long or plus lead that are equivalent to a standard or perfect thread. The line *AB* similarly represents *all* oversize threads 1 in. long with a short or minus lead.[1]

The lines *AC* and *AC'* represent taps equivalent to standard for threads 5/8 in. long and *AD* and *AD'* for threads 1.25 in. long, the amounts over standard for *CC'* and *DD'* being respectively 5/8 and $1\frac{1}{4}$ times *B* (17.3) for a lead error of 0.001 in.

The oblique lines on the charts, Tables 1 to 18, are similar lines for the maximum length of thread specified in the table

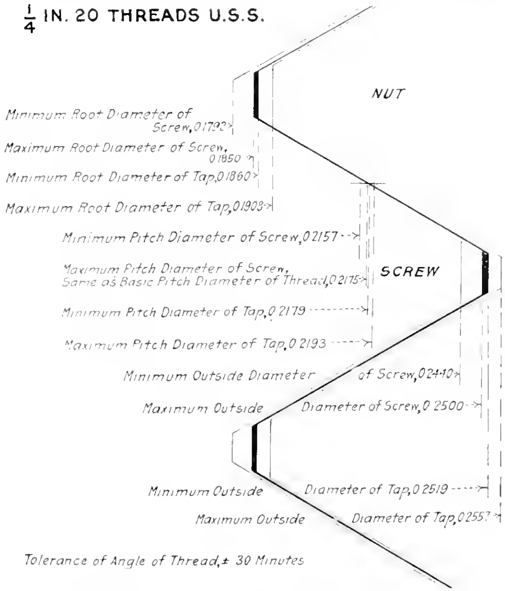

Fig. 4 Relation of Screw and Nut, Showing Maximum and Minimum Allowances

alongside of each chart. For screws these lines pass through zero and represent equivalents of perfect screws. For taps and nuts these lines pass through a point slightly above the zero point in order to keep all taps and nuts slightly over standard.

In Fig. 3, the points *HJ* where the upper and lower lines intersect the perfect lead line, represent the extreme limits for the pitch diameters of a nut and screw with perfect lead, and the distance between these two points represents the maximum diametrical shake between any nut and screw falling within the shaded areas or zones of the chart, while the average shake would be about one-half of this maximum shake.

It is assumed that a tap makes a hole the exact counterpart of itself, therefore taps and nuts are referred to as having identically the same pitch diameter and lead.

How to Use the Tables

For a Tap:

a Find the actual pitch diameter of the tap with a "V"-thread micrometer. Look in left-hand column at the bottom of the table for taps for the required size (Tables 1 to 18) for this diameter. If the diameter is less than the first figure or greater than the last figure of the column, the tap is not within the limits required.

b When the diameter is found in the table, read to the right in the next column the amount it is *over basic* pitch diameter. Read again to the right in the third column the allowable "errors in lead" for this pitch diameter.

[1] The shorter the length of thread the more nearly horizontal this line becomes, and for a zero length of thread it becomes horizontal, coinciding with the horizontal zero line *OA*. Similarly the greater the length of thread the more nearly vertical this line becomes.

OCT 29, 1917

TABLE 16

c Next find the actual error in lead per inch with some lead-measuring instrument. If the actual error is within the limits given in the third column, then the tap is correct for both pitch diameter and lead.

Example: For 1/4 in., 20 thread tap, for threads from 0 to 1/4 in. long, refer to Table 1 and under "For a Tap or Nut." Suppose the pitch diameter of a tap is 0.2185 in. Find this figure in the first column; to the right the next column shows the tap as 0.0010 in. over basic pitch diameter, and the third column shows that its lead must be between 0.0018 in. fine (minus) to 0.0018 in. coarse (plus) per inch to be within the limits of this table.

For a Screw:

d Find the actual pitch diameter of the screw with a "V"-thread micrometer. Look in the last column at the bottom of the table for screws for the required size (Tables 1 to 18) for this diameter. If the diameter is less than the first figure or greater than the last figure in the column, the screw is not within the limits required.

e When the diameter is found, read to the left in the next column to the left the amount that it is *under basic* pitch diameter. Read again in the third column to the left the allowable error in lead for this pitch diameter.

f Next find the actual error in lead per inch with some lead-measuring instrument. If the actual error is within the limits given in the third column to the left, then the screw is correct for both pitch diameter and lead.

Example: For 1/4 in., 20 thread screw, for threads from 0 to 1/4 in. long refer to Table 1, and under "For a Screw or Bolt." Suppose the pitch diameter of a screw is 0.2160 in. Find this figure in the last column; the next column to the left shows the screw as 0.0015 in. under basic pitch diameter, and the third column to the left shows that its lead must be between 0.0023 in. fine (minus) and 0.0023 in. coarse (plus) to be within the limits of the table.

For Screws and Taps:

g If the actual pitch diameter for either tap or screw is within the range of the tables, but the exact diameter is not given in the proper column, it can be interpolated, or reckoned as between the two nearest values given, and a proportionate and corresponding limit can be likewise interpolated in order to find the error in lead allowable for the actual pitch diameter in hand.

Example: Same table. Suppose the pitch diameter of a tap is 0.2188 in. In the first column for taps it would come between 0.2185 in. and 0.2190 in. and the value for the next column would be 3/5 of the way between 0.0010 and 0.0015 in. or 0.0013 in., and the value for the third column would be 3/5 of the way between 0.0018 in. and 0.0029 in., or 0.0025 in.

If the length of engagement is greater than that provided for in the tables, reference can be made to the table for a larger size having the required length, and the allowable variations in lead thus found.

Example: Suppose a 1/4-in. 20 screw is to extend into a tapped hole for a depth of 1/2 in., or two diameters. Refer to the diagram Table 5 for a hole 1/2 in. deep, this being for 1/2 in. 13, which allows for a fit 1/2 in. long. This will show by the angular lines what variations in lead are allowable, bearing in mind that the variations in pitch diameter must still be kept within the limits given in Table 1 for 1/4 in.

Example: Suppose a 1-in. 8 bolt is to be used with a nut 3/4 in. thick. Refer to the diagram Table 8, which allows for a fit 3/4 in. long. This allows for a greater variation in lead than the diagram for 1 in., Table 10. The greater limits in pitch diameter allowed for 1 in. can also be used, however.

TABLE 18

Formulæ for Medium-Fit Screws, Nuts, Taps, Etc., Suited for General Use

SYMBOLS USED IN FORMULÆ

Basic full or external diameter	$= D$
Basic pitch diameter	$= E$
Basic root diameter	$= K$
Number of threads per inch	$= n$
Normal lead	$= L$

SCREWS

Max. external diam. $= D$

Max. pitch diam. $= E$

Max. root diam. $= K$

Min external diam. $= D - \left(\frac{0.102}{n} + \frac{0.054}{n+40}\right)$

Min pitch diam. $= E - (0.0045 \times \sqrt{D} - 0.0005)$

Min. root diam. $= K - \left(\frac{0.033}{n} + \frac{25}{n+40}\right)$

Max. error (± normal) allowable in lead per inch. Length of engagement up to one diam. $= \frac{0.57735\,(0.0045 \times \sqrt{D} - 0.0005)}{D}$

(This formula also applies to tapped holes.)

TAPS AND TAPPED HOLES

Max. external diam. $= D + \frac{0.04}{n} + \frac{0.224}{n+40}$

Max. pitch diam. $= E + 0.0045 \times \sqrt{D} - 0.0005$

Max. root diam. $= K + \frac{0.033}{n} + \frac{0.25}{n+40}$

Min. external diam. $= D + \frac{0.112}{n+40}$

Min pitch diam. $= E + \frac{0.0045 \times \sqrt{D} - 0.0005}{4}$

Min. root diam. $= K + \frac{0.02}{n}$

TAPS ONLY

Max. error (± normal) allowable in lead =

$$\text{Max. error } (\pm \text{ normal}) \text{ allowable in lead of screw} - \frac{\left(\begin{array}{c}\text{Max. error } (\pm \text{ normal})\\ \text{allowable in lead of screw}\end{array}\right)}{0.03}$$

Applying Formulæ and Tables for Pitches Other Than U. S. S.

The diagram, Fig. 4, illustrates the relation of the screw to the tapped hole, showing maximum and minimum allowances.

As the formulæ given above for external and root diameters are based on the number of threads per inch, the maximum and minimum limits are not changed by a change in diameter and the allowances given in the formulæ for the U. S. Standard diameter and pitch can be used.[1]

Example: 1 in. diameter, 20 threads to the inch. For external diameter for ¼ in. 20 it will be found from the formula (or by reference to Fig. 7) that the maximum for screws is basic while the minimum is 0.0060 under. The maximum for tap or nut is +0.0057 in., while the minimum is +0.0019 in., these allowances being always the same for 20 threads to the inch for any diameter. The allowances for pitch diameter and lead, however, are based on formulæ having the diameter as a factor.

Example: 1 in. diameter, 20 threads to the inch. It will be found by the formula (or by reference to Figs. 5 and 6) that the maximum pitch diameter of screw is basic. Minimum pitch diameter $= 1 - (0.0045 \times \sqrt{1} - 0.0005) = 1 - 0.004 = 0.996$ min. pitch diam. of screw.

Maximum pitch diameter of tap $= 1 + 0.004 = 1.004$ in.

Minimum pitch diameter of tap $= 1 + (0.004\ \ 4) = 1.001$ in.

Maximum error (± normal) allowable in lead of screws if the length of engagement = 1 diameter (in this example 1 in.) =

$$\frac{0.57735\ (0.0045 \times \sqrt{1} - 0.005)}{1} = 0.0023 \text{ max. error in lead.}$$

If, however, the length of engagement is only ½ in. instead of 1 in., a proportionately greater error in lead can be allowed.

0.0023 ÷ ½ = 0.0046 in. maximum error in lead for 1 in. 20 threads with ½ in. length of engagement.

Maximum error in lead for tap for 1 in. length of engagement

$$0.0023 - \frac{0.0023}{0.03} - 0.0017 \text{ max. error in lead.}$$

For ½ length of engagement, 0.0017 ÷ ½ = 0.0034.

To Find Position of a Tap or Screw in the Chart, Fig. 3

First, find its actual pitch or angular diameter as measured with a "V"-thread micrometer. Subtract from this diameter the basic pitch diameter as given in the table. The difference will be its deviation from basic pitch diameter. If plus, lay off its value to scale above the horizontal coördinate line; and if minus, below the horizontal line.

Second, find the "error in lead per inch" with a lead measuring instrument. If the lead is coarse, equal plus, lay off its value to scale to the right of the vertical coördinate line, or if fine, equal minus, lay it off to the left of the vertical line.

The point where these first and second values intersect is the position of the tap or screw on the chart. If it is within the shaded area, the tap or screw is within the prescribed limits, and if outside of the shaded area it is not up to the standard represented by the chart and table. Taps and nuts must fall within the shaded area above the horizontal line; while screws and bolts must fall within the shaded area below the horizontal line.

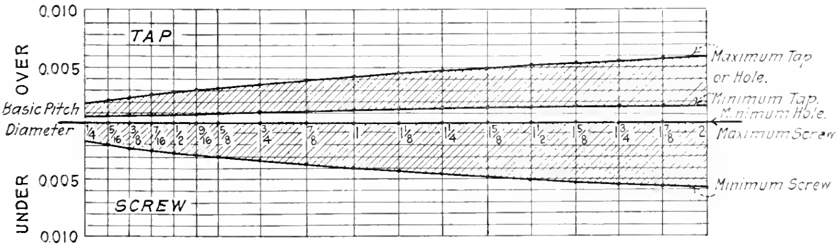

Fig. 5 Maximum and Minimum Clearance, Pitch Diameter

Example for a Tap: Suppose a tap measured 0.001 in. over basic pitch diameter; this value would fall on the horizontal line CK (Fig. 3), and if its lead should be 0.0005 in. fine or minus in 1 in., this value would fall on the vertical dotted line passing through K, and the tap falls within the area of the chart.

Example for a Screw: Suppose a screw measured 0.0010 in. under basic pitch diameter, it would then fall on the horizontal line AL (Fig. 3), and if its lead were 0.0020 in. coarse or plus it would fall on the vertical dotted line passing through L, and the s rew falls outside the area of the chart.

[1] These limits can also be obtained by reference to Figs. 7 and 8.

GAGING DEVICES

In order to ascertain whether the work comes within the required limits as represented by the triangular zones of the tables, it is desirable to measure simultaneously both the pitch diameter and the lead.

Among the tools suggested for accomplishing this purpose allow for variations in lead. This roll is set to the standard pitch diameter of the work and is adjusted by the micrometer thimble. The floating point is so connected that the longer lever shows the variation in lead and the shorter lever variations in pitch diameter, each pivoting about its own center. The work is placed between the points as shown by the dotted

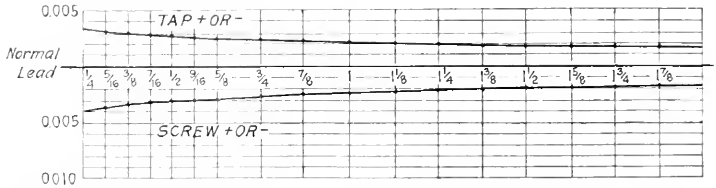

Fig. 6 Allowable Variation in Lead Over or Under Normal for Maximum Error in Diameter

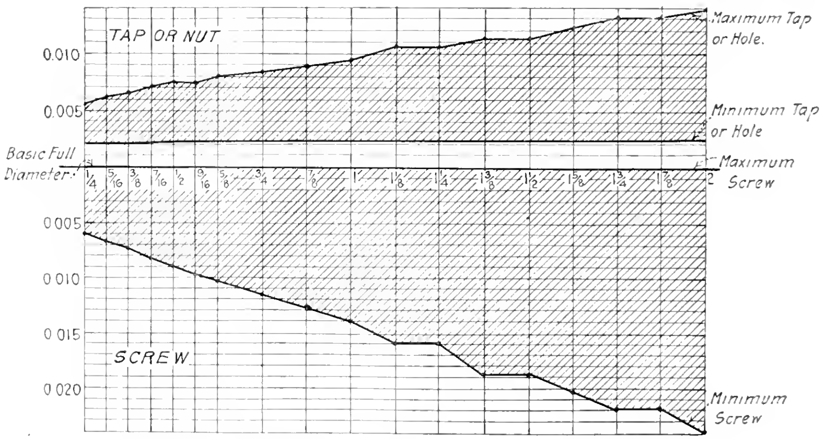

Fig. 7 Maximum and Minimum Clearance, Full or External Diameter

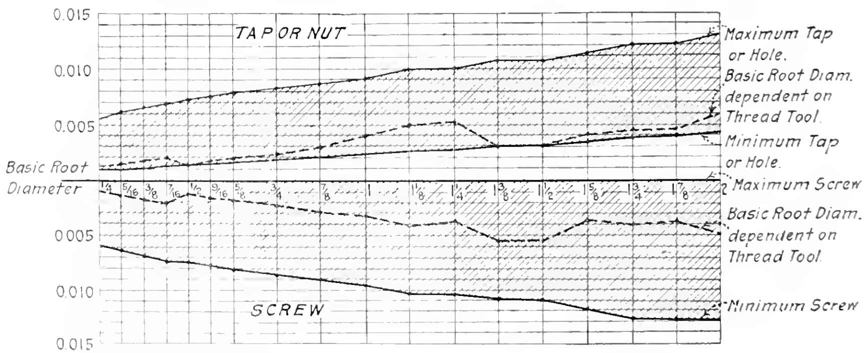

Fig. 8 Maximum and Minimum Clearance, Root Diameter

are the following: In Fig. 9 is shown a gage which is adjustable for a range of diameters, the micrometer thimble being used to obtain the readings for the diameter. An adjustable block supports the work so that it will be held parallel to the center line and can be set to be measured on the center line. The grooved roll fits over the thread and is free sideways to section, and the variations from standard or pitch diameter and lead are read directly in thousandths of an inch.

In Fig. 10 is a combination gage for diameter and lead. Point A is adjustable longitudinally by means of a micrometer screw so that it can be placed in proper relation to B, which is adjustable for different diameters, the pitch diameter of work

being read directly by means of its micrometer. The point C is connected to the indicator, variations being read directly on the scale in thousandths of an inch. A block supports the work in proper relation to the gage points, and is set by means of the micrometer D.

A combination gage for pitch diameter and lead, having a fixed point and two adjustable points, is shown in Fig. 11.

between the screw and nut or tapped hole, work which will pass inspection by the gages will interchange in use, and thus the desired result will be attained.

Where expensive special tools are not available good results can be obtained by measuring the diameter with an ordinary *screw-thread micrometer* shown in Fig. 14, and the lead, with the *lead-measuring indicator*, shown in Fig. 15. By the combined use of gages shown in Figs. 14 and 15, it can readily be determined whether the work will come within the triangular zones on the tables, and thus pass inspection.

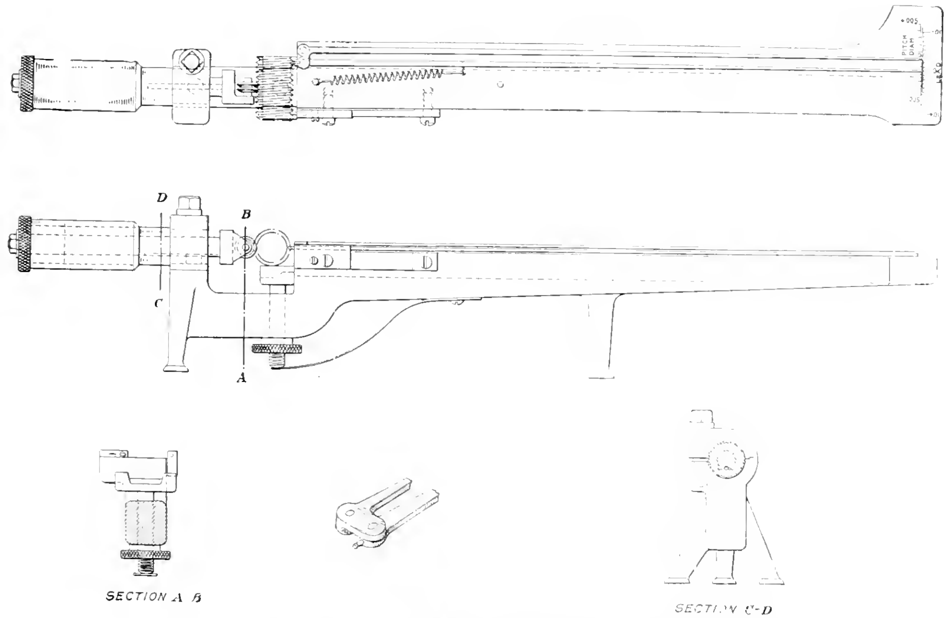

Fig. 9 Combined Lead- and Diameter-Measuring Gage, with Compound Levers

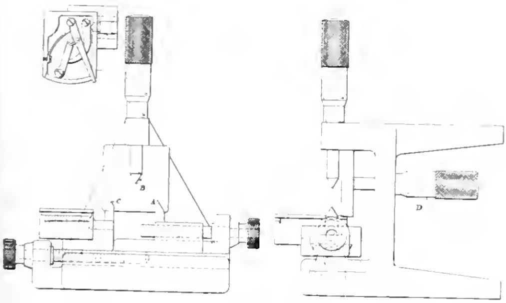

Fig. 10 Combined Lead- and Diameter-Measuring Gage, with Micrometer and Lever Indicator Readings

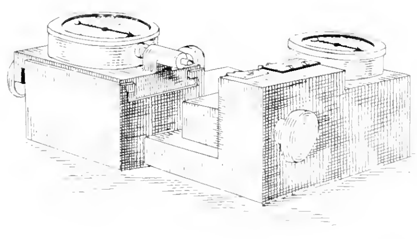

Fig. 11 Gage with Dial Indicator Readings

The variations in both cases are read on the dial indicators in thousandths of an inch. Indicators must be set to a standard before testing the work. An adjustable block may be set by a vernier or micrometer so that work resting on it will have its center line in line with the gage points.

In Figs. 12 and 13 is shown the type of gages now generally in use for measuring screw threads. Gages of this type do not determine the combined error of lead and diameter, but are satisfactory for many classes of work. If the thickness or length of gage is made to correspond with the length of fit

Another lead-measuring instrument is shown in Fig. 16. This uses a commercial test indicator for noting the variations from correct lead.

Fig. 17 shows a simple gage which might be provided at small expense where a block of a thickness of about one or one and one-half diameters is tapped at one end for approximately standard pitch diameter and correct lead, while the other end is made thin and tapped under standard pitch diameter so as to be used as a minimum-diameter gage. A screw which will pass through the standard or thicker gage but will not pass through the thin gage may be presumed to be within

the required limits of tolerances for variation in both lead and pitch diameter.

Many other designs of measuring instruments have been submitted to the committee, having points of excellence, but

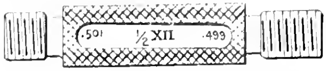

FIG. 12 PLUG GAGE

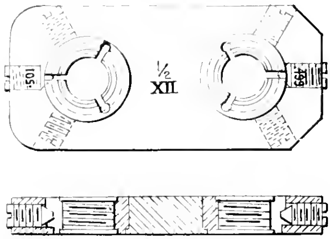

FIG. 13 RING GAGE

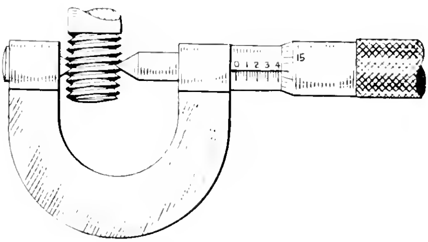

FIG. 14 SCREW-THREAD MICROMETER

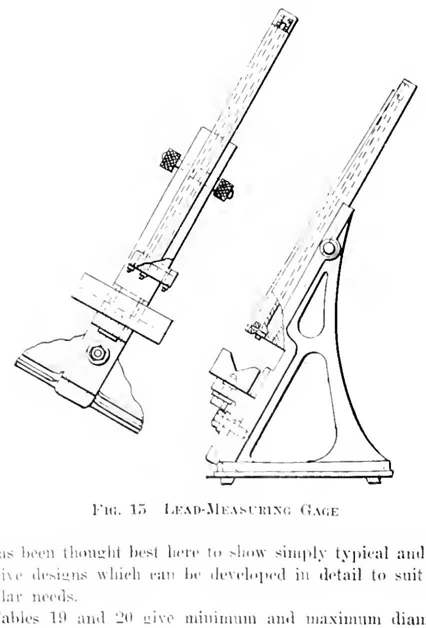

FIG. 15 LEAD-MEASURING GAGE

it has been thought best here to show simply typical and suggestive designs which can be developed in detail to suit particular needs.

Tables 19 and 20 give minimum and maximum diameters for U. S. S. taps, nuts and screws; while Tables 21 and 22 give inspection limits for taps and screws, with the varying allowance in lead for different diameters within the limits specified.

DEFINITIONS AND SYMBOLS

The letter symbols given below are those recommended by the U. S. Bureau of Standards:

Allowance. Variation in dimensions to allow for different qualities of fit.

Angle Diameter. Same as pitch or effective diameter.

Angle of Thread, "A." The total or included angle between the sides or slopes of a thread, in a plane passing through the axis of the screw or nut.

Clearance. The space between a screw and a threaded hole.

Clearance Angle. Allowance on the angles or slopes of the thread for screw threads to fit together.

Clearance, Bottom. Allowance or space at bottom of a thread to prevent a bearing at this point and to provide space for dirt.

Clearance, Outside. Allowance between outside diameter of screw and bottom of tapped hole.

Core Diameter, "K." English term for the root or bottom diameter of a screw and the small diameter of a nut. In the case of the nut it is measured between the crests of the thread. See Root Diameter.

Crest. English term for the top or most prominent part of a thread, whether on the screw or in the nut.

Effective Diameter, "E." English term for pitch diameter and defined as the length of a line drawn through the axis and at right angles to it, measured between the points where the line cuts the slopes of the thread.

External Diameter, "D." Same as full diameter or outside diameter.

Finger Fit. Where the screw fits the tapped hole so as to just be screwed in with the fingers.

Flow of Thread. The movement of metal in a screw or nut, or both, when screwed together by force, to fit in spite of an error in lead.

Flute. The groove cut in taps and reamers to form cutting edges and to allow room for chips.

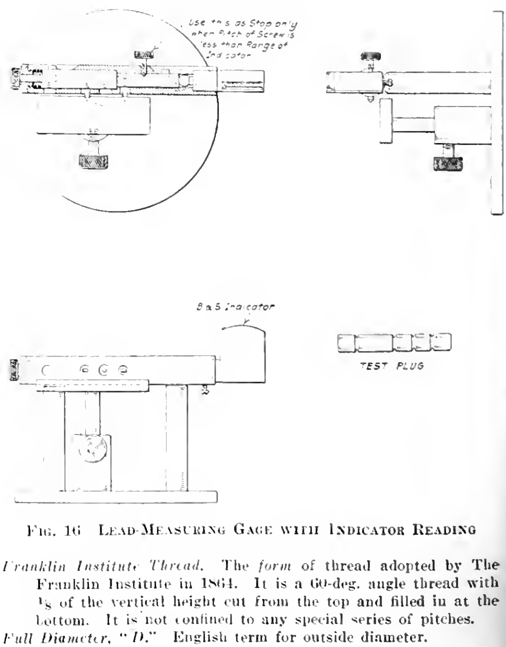

FIG. 16 LEAD-MEASURING GAGE WITH INDICATOR READING

Franklin Institute Thread. The *form* of thread adopted by The Franklin Institute in 1864. It is a 60-deg. angle thread with ⅛ of the vertical height cut from the top and filled in at the bottom. It is not confined to any special series of pitches.

Full Diameter, "D." English term for outside diameter.

Gage, Check or Checking. Gage for checking or testing other gages.

Gage, Limit. A gage for insuring that any given dimension is within the tolerance laid down for the class of work to be produced.

Gage, Master. A gage which is kept as a standard, solely for comparing reference gages.

Gage, Reference. A gage used by the manufacturer and by which the workman's gage is tested. A copy of the Master Gage.

Gage, Shop or Workman's. A gage used by the workman in everyday practice. It is tested by or with the Reference Gage.

Gage, Standard. English term for Master Gage.

Land. The space between flutes on a tap or reamer. It includes the cutting edge and the supporting metal behind it.

Lead, "L." The distance a screw advances in one turn. In a single-thread screw this is the same as pitch.

Lead, Normal. "L." Correct lead.

Lead per Inch. The lead multiplied by its reciprocal. For a perfect thread this equals one inch.

Limits. Two sizes expressed by positive dimensions, the larger being termed the maximum, and the smaller the minimum, limit.

Limit Gage. See Gage, Limit.

Outside Diameter, "D." Diameter on the outside of the thread. External or full diameter.

Pitch. The distance from a given point on one thread to a similar point on the next thread, along the axis of the screw. The same as lead for a single thread. The reciprocal of threads per inch.

Pitch Diameter, "E." Same as effective diameter. Also defined as the diameter of a screw at a point midway of the depth of the thread. Equal to the outside diameter less the depth of one thread. This depth equals:

For "V"-threads $= \dfrac{0.866}{\text{Thds. per inch}}$ For U. S. S. $= \dfrac{0.6495}{\text{Thds. per inch}}$

Relief. The reduced diameter behind the cutting edge of a tap.

Root. Bottom or smallest diameter of thread, whether in screw or nut.

Root Diameter, "K." The smallest diameter, whether for a screw or in a nut.

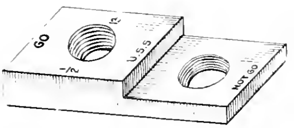

Fig. 17 Cheap Gage for Temporary Use

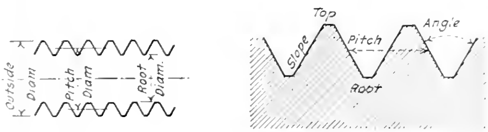

Fig. 18 Diagrams Showing Elements of Thread

Slope of Thread. The angular part which connects the large and small diameters of a thread.

Standard Gage. English term for Master Gage. (See Gage, Master.)

Thread, Modified "V." A form of thread having a 60-deg. angle and such that if carried to a sharp point it would measure to the nominal size, but with the top or bottom, or both, modified usually by being flattened according to conditions or individual ideas.

Thread, U. S. S. The standard adopted by the United States Government, which uses the Franklin Institute form of thread with a definite pitch for each diameter. (See Franklin Institute Thread.)

Thread, "V." A form of thread having a 60-deg. angle and sharp at top and bottom. Impossible in practice and always more or less modified, whether intentionally or not.

Thread, Whitworth. A thread having a 55-deg. angle and a rounded top and bottom. The proportions are:

Depth $= \dfrac{0.640327}{\text{Thds. per in.}}$. Radius of top and bottom $= \dfrac{0.137329}{\text{Thds. per in.}}$

Thread Micrometer. A micrometer caliper with special points for measuring the pitch or angle diameter of the screw.

Threads per Inch, "n." Number of threads in one inch of length.

Tolerance. The allowable variation in size, equal to the difference between the minimum and maximum limits.

Turns per Inch, "N." The number of turns required to advance one inch. Equal to the threads per inch of a single-threaded screw.

Wrench Fit. Where the screw fits the tapped hole so tightly as to require a wrench to screw into place. Used for cylinder studs in steam engines and for similar work.

Table 9, Limits on Pitch Diameter at Perfect Lead: Under "Screw or Bolt" read 0.7992 min. instead of 0.8012 min.

Table 18, Allowable Error in Lead per Inch for Actual Pitch Diameter: Under column headed "Tapped Hole" read ± 0.0013 instead of ± 0.0012.

The Food Administration has recently issued a message urging conservation of ammonia. During 1918, it is stated, the Government should have for munitions alone 20,000,000 lb. of ammonia more than it is possible to make by working all the plants producing ammonia in this country to their maximum capacity.

This shortage will be greatly increased by the ammonia that will be furnished ice-making and refrigerating plants, but it is hoped that by appealing to the patriotism and business sense of all ammonia users and urging them to stop all waste and leakage, the usual consumption may be curtailed to such an extent as will permit at least the most efficient plants to run; particularly where natural ice is not available.

The returns lately received show that much ammonia loss is avoidable. Many plants use less than one-twentieth of a pound per ton of ice made; while others use from one-half to one pound per ton. The same inexcusable waste is found in many refrigerating plants. The only reason that can be given for permitting the enormous waste and expense to continue at some plants is that the management has not informed itself as to what is a reasonable consumption and the operating force is indifferent about leaks that might easily be stopped but are allowed to continue.

A saving of 25 per cent in the ammonia consumption of ice and refrigerating plants would mean several million pounds annually for munitions. Each pound will make twenty hand grenades. Late returns show this saving can be accomplished if all will stop the leaks.

The Ford Administration has also given out figures showing that in one ton of garbage there is sufficient glycerin to make the explosive charge for fourteen 75-mm. shells, enough "fatty acid" to manufacture 75 lb. of soap, fertilizer elements to grow 8 bu. of wheat, and a score of other valuable materials essential in munitions manufacture.

DISCUSSION OF SPRING MEETING PAPERS

ONE of the papers presented at the second General Session of the Spring Meeting at Worcester which, by reason of the keen interest now taken in matters relating to the subject of flight and the novel ideas advanced by the author, drew forth much illuminating discussion, was that by Prof. Morgan Brooks, on Air Propulsion.

In this paper, an extended abstract of which was printed in THE JOURNAL for May (p. 390), the author describes experiments with propellers showing that the accepted screw theory of air propulsion does not accord with the facts. In these experiments air was impelled by a propeller at a speed approaching twice the screw advance for small blade angles, hence the theory of reflection or batting action should replace the screw theory. Thrust is shown to be due in greater degree to velocity and less to blade disk area than is commonly supposed.

In presenting the paper Professor Brooks said that although the facts stated seemed impossible to many, their essential accuracy could be absolutely depended upon. The substitute reflection theory advanced he offered without claims as to its correctness, but as a suggestion open to criticism and alteration.

Those contributing to the discussion were N. W. Akimoff, C. W. Howell, G. De Bothezat, Dr. S. W. Stratton, L. R. Gulley, J. C. Hunsaker, M. B. Sellers, Lieut.-Col. J. S. Vincent, W. C. Durfee and H. F. Hagen, whose remarks immediately follow.

AIR PROPULSION

DISCUSSION OF PAPER BY PROF. MORGAN BROOKS

N. W. AKIMOFF (written). Professor Brooks' paper will be welcomed by the profession only in so far as it represents a sincere opinion, purely subjective, of that capable engineer. In itself the paper is open to grave objections. The theory proposed apparently contemplates an infinite space of 30 in. vacuum, in which floats one particle of air, how large is so far unknown. The propeller blade runs into it and, in turn, experiences a little reaction, although the particle feels it much more than the blade itself. Splendid! but what becomes of the hydrodynamics of this delicate problem? All propeller theories that are based on supposing that the air is a material aggregation of separate particles are absolutely worthless: the screws built according to such theories are as likely to give 84 per cent as 48 per cent, because the very foundation is shaky.

The least unsatisfactory theory of propellers is that which takes into consideration the vortex theory of sustentation. Lanchester claims priority to the idea, although many other scientists of not quite so great repute also claim to have discovered it first. (See A Review of Hydrodynamical Theory, etc., by J. S. Hunsaker, International Engineering Congress, San Francisco, September 1915.)

He who looks into the vortex theory of sustentation will at once abandon theories about air particles as related to pitch or slip. Here the lift is made dependent upon a certain section constant, called circulation, and is equal to density times circulation times velocity *ad infinitum*.

The propeller blade can also be considered as a set of regular wing sections, say, RAF 6, or whatever they are, for which the "circulation" is either known or can be calculated. This has been done with satisfactory results; the trouble is that all such methods require a little knowledge, which certainly is most unfortunate; what we would like to have is a pocket book, or a table of some sort, but it does not work that way. Highly delicate is the confounded science of hydrodynamics!

Fig. 3 of Mr. Brooks' paper looks unusual; it has very likely been drawn by inference and not as a result of calculations.

The subject of static tests as a basis for judging of what the dynamic pull will be, is one of extreme difficulty, and here again the vortex theory is the only hope.

For the estimation of what the static pull will be within, say, 15 per cent or so, the writer has recently proposed the following crude formula: Static pull in lb. $= n^2D^4/2750$. (*Aviation*, 1917.) This appears to serve the purpose, but only within the prescribed limits; to estimate the pull of a screw is about the same as to build a helicopter screw—a difficult problem.

CHARLES W. HOWELL[1] (written). Recognition must be accorded the superspeed or acceleration theory so ably set forth by Professor Brooks, if it is desired to clear away the misconception existing as to the result of the application of power to a rotating element having angularly disposed surfaces to produce useful work in such a light and elastic medium as air, and if it is also desired to reduce the proposition to an exact status so that better working formulæ may be had.

Superspeed, as Professor Brooks states, is not readily observed in a static test of a two-blade propeller, but conversely may be directly observed in translational or flying tests of conventional airplanes, which have frequently been observed to fly a greater distance in unit time than the revolutions-times-pitch design of their propellers should fly them. Were this phenomenon confined to airplanes flying *with* the wind, we might assume, with reason, that it was merely the product of pitch minus slip, plus the velocity of the wind, but as the phenomenon may be observed to occur in substantially inert air and to a lesser degree in flying *against* moderate wind, it can only be explained in terms of velocity and impact—i. e., superspeed.

The air structure shown in Fig. 3 is quite characteristic of those produced under static tests by propellers of screw-pitch design. It has been observed, however, to vary radically under flying conditions, a beautifully clear example being shown by a screw-pitch propeller driven by a Gnome motor. This is a rotating-cylinder motor lubricated by castor oil, which frequently causes black smoke to be emitted from the exhaust ports. This smoke does not take the form of a rotating, contracting swirl, but forms into two ribbons or pennants which do not rotate but appear to change position with variation of motor speed.

It has also been noted that propellers differing from the conventional screw-pitch design will set up various forms of air structures. One has been observed to create a column substantially parallel and with small tendency to rotate. This would appear to approach the ideal condition, as it indicates a reduction of interference losses; that is, maximum acceleration or superspeed has occurred.

Experimental research with small model propellers appears to indicate that the air structure formed is influenced largely by the design of the rear or leaving edge of the propeller blade and may have a strong bearing on its efficiency, because the smaller the interference with or the mixing of the super-

[1] Vice-President, Aeronautical Society of America.

speeded air particles, the more parallel will be the lines of force and the greater the efficiency.

May I venture to suggest the term "acceleration" as more indicative of the physical result, and to express the opinion that the problem can be reduced to a precise condition and understanding by throwing out all considerations of screw and pitch and considering velocities and impact only?

G. De Bothezat (written).[1] The following may serve as a basis for a discussion of the flow of a fluid along a section of a propeller blade. Let it be assumed that we know exactly the direction along which the flowing fluid reaches a section of the blade (this theory determines exactly this direction). The following phenomena have then to be considered: If the flow reaches the blade section with a velocity W_1, it leaves it with a velocity W_2 (Fig. 1), which differs from W_1 in magnitude (slightly) and in direction.

At the points of contact of the fluid with the blade section there take place several quite complex phenomena of shocks and eddy formations. If the angle at which W_1 strikes the section of the blade is sufficiently small, then in the first approximation and using the terminology adopted in Professor Brooks' paper, W_1 is reflected on to the plane pp (Fig. 2) normal to the *resultant of pressure* R exerted by the flowing fluid on the section of the blade under consideration. As a rule, this plane pp is not parallel to the chord cc of the section, but for small angles of attack (but not extremely small) the angle between cc and pp is not large. This applies only to small angles of incidence between W_1 and the section under consideration, and is correct only in the first approximation, though sufficiently correct for practical purposes.

I have arrived at this conclusion from a study of the phenomena of flow, and this is only an attempt to indicate more precisely the direction of the plane of reflection experimentally discovered by Professor Brooks. But there is more to it. As the incidence of W_1 with respect to the section increases, then, from a certain moment on, the flow of the fluid in the rear of the section ceases to be permanent, and eddies are formed to the rear of the section (Fig. 3). This fact is beyond all doubt, and is confirmed by numerous experimental investigations, as, for example, those carried out at Teddington. In such a case it is more difficult to speak of the direction of the reflected air current, and it becomes necessary to introduce the conception of a current equivalent to the complex system of flow.

It can easily be seen how really complex is this problem, but the method which I use in my theory enables me to take into account all the phases of the phenomena of flow without having to resort to any simplifying assumptions. However, before I can explain how I attained this result, I have one more remark to make.

Let us consider a section of the blade which the air current strikes successively in the directions W_1, W_2, W_3 and W_0 (Fig. 4). The first resultants of the fluid pressure will be respectively R_1, R_2, R_3 and R_0, which means that as the incidence of W with respect to the section of the blade decreases, the resistance of R comes, so to speak, to lie in the section, and finally a moment arrives when W and R have the same direction. At that moment R has no component in a direction normal to W. I call *zero plane* (*zero* straight *line* on the section) the plane containing R_0 and W_0 when the component of R normal to W is zero. This zero line is located as indicated in the figure for nearly all sections of a propeller blade, and the angle which the zero line makes with chord cc (Fig. 5) depends on the profile of the section and may reach values in excess of 10 deg. For the majority of sections which I have examined this angle is comprised between 3 deg. and 12 deg.

When it is desired to compare a section of the blade to a thin ideal plane (geometric), it is of the utmost importance that the start should be made from the zero line and that all the characteristics of the section should be referred to it. Thus, the incidence or angles of attack should be measured only from

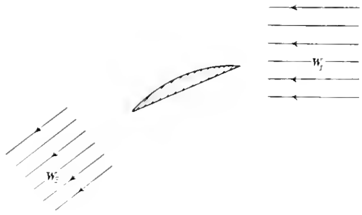

Fig. 1

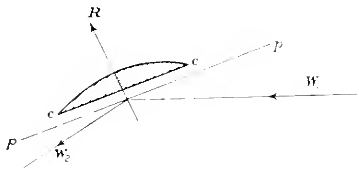

Fig. 2

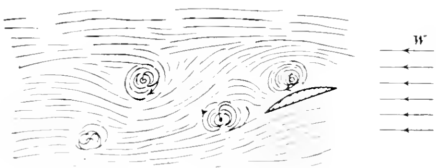

Fig. 3

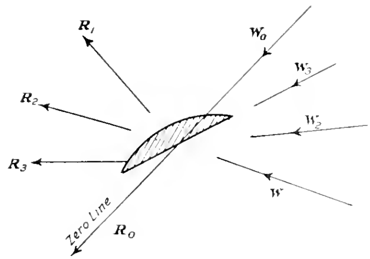

Fig. 4

this zero plane. Likewise the pitch of the sections should be measured from the zero line and not from the chord.

The greater part of all misunderstandings concerning propellers are due to this fact. In Fig. 6, r is the distance from the axis of the propeller of the section under consideration; H is the pitch measured from the zero line, W the velocity of the flow of fluid as it reaches the section under consideration. I call the pitch H when measured in the way indicated above

[1] D.Sc., University of Paris. Now acting in an advisory capacity to the Aircraft Administration, Washington, D. C.

effective pitch as opposed to the geometric or constructive pitch measured from the chord. Only the effective pitch can be considered as the geometric and real characteristic of the propeller, and the author fully agrees with Professor Brooks in that the only possible definition for slip is

$$s = \frac{H - (V/N)}{H} = 1 - \frac{V}{NH}$$

where V = velocity of translation
N = number of revolutions
H = effective pitch.

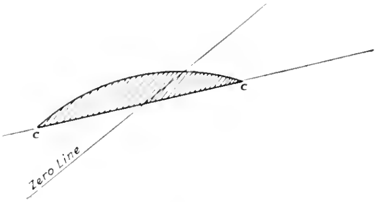

FIG. 5

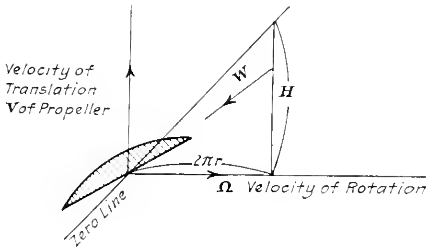

FIG. 6

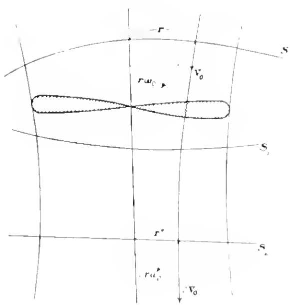

FIG. 7

It is the effective pitch which should be taken in measurements. The *effective pitch* is always greater than the *constructive pitch*, and that is why if for H in the above formula were taken the values of the constructive pitch, it might happen that negative values would be obtained for the propeller slip s, which is contrary to reason. The effective pitch, on the other hand, always gives positive values for s and the consideration of the effective pitch H is all that is necessary in order that the difficulties in the way of understanding the exact results of the experiments of Professor Brooks should disappear completely.

Let us consider the fluid stream generated by the rotation of a propeller; in particular, the case of a propeller rotating on a stationary basis (the following reasoning is, however, perfectly general).

I designate by S_1 (Fig. 7) the furthermost section to the rear of the propeller and by $2v_0$ the velocity at one point of that section. $2v_0$ is the velocity of the fluid parallel to the axis of rotation at the given point and $2r''\omega_0^2$ is the tangential component of this velocity. The real movement of the fluid is obviously helicoidal.

I show elsewhere that the section S in which the velocities of the fluid are v_0^2 and $r\omega_0^2$, that is, exactly one-half of the velocities at the section S_2, must be located necessarily in the front part of the propeller and at a certain distance from it. The propeller is, therefore, necessarily comprised between the sections S and S_2. The section S_1 is that which the eddy phenomena created by the propeller have already ceased to exist and the flow of air has become regular once more. The flow ahead of S is also regular, and my theory gives the exact values of the velocities v_0 and rw_0 (or $2v_2$ and $2r''\ \omega_0$).

The following are the values above referred to:

$$v_0 = r\Omega_0\zeta_0 \tan(\varphi + \beta_0)$$
$$\omega_0 = 2\Omega_0\zeta_0 \tan^2(\varphi + \beta_0)$$

These formulæ will show, in the first place, in accordance

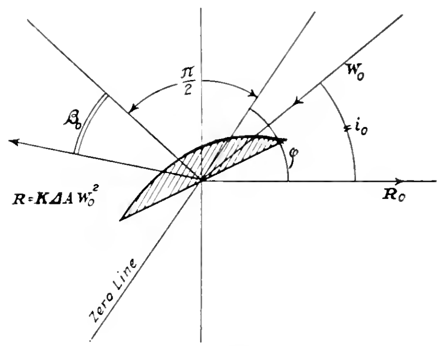

FIG. 8

with the experiments of Professor Brooks, that the ratios v_0/Ω_0 and ω_0/Ω_0 are independent of the number of revolutions $N = \frac{\Omega_0}{2\pi}$. In these formulæ

$$\zeta_0 = \frac{\frac{1}{2}\Delta M(2v_0)^2}{\Omega_0\Delta C_0} = \frac{v_0\Delta Q_0}{\Omega_0\Delta C_0} = \frac{\tan(\varphi - i_0)}{\tan(\varphi + \beta_0)[1 + 2\tan(\varphi - i_0)\tan(\varphi + \beta_0)]}$$

and with i_0 secured from this ratio, we have

$$u = \frac{nb}{2\pi r} = \frac{2\sin^2(\varphi - i_0)}{k_i \cos(\varphi + \beta_0)}$$

These formulæ contain by implication the fact that the velocity at a certain point in the fluid depends only upon the characteristics of the section of the propeller blade swept over by the fluid stream passing at that point, which is true as long as the radial velocities are negligible.

In these formulæ ΔQ_0 and ΔC_0 are the thrust and partial couple which correspond to the section of the blade under consideration and ΔM is the fluid mass which in a unit of time

passes across the annular space swept over by the section under consideration.

Let

φ = the angle of inclination of the zero line of the section under consideration on the plane of rotation

i_0= angle of attack

k_i and β, are the aerodynamic characteristics of the section under consideration (Fig. 8)

n = the number of blades

b = the width of the blades

nb = the total width.

These formulæ for v_0 and w_0 show again that the fluid stream generated by the rotation of a fixed-base propeller is geometrically similar to itself, independently of the velocity of rotation of the propeller, and the rear angles of attack i_0 are independent of the value of Ω. The values of the angles i_0 depend only on the shape of the blade and its pitch.

I have already by experiments confirmed the values of v_0 and w_0 given by my theory.

S. W. Stratton[1] (written). The type of propeller employed by Professor Brooks in his experimental work differs so widely from the types in actual use that the extent to which the air-bat concept can be applied to propeller design cannot be foreseen. The new viewpoint is stimulating and suggestive, and especially welcome in connection with airplane propellers, where it is difficult to visualize what is actually taking place.

L. R. Gulley (written). It was the writer's good fortune to observe a few of the tests made by Professor Brooks, the results of which form the basis of this paper. On first examination, the most evident proof of the superspeed effect was the result obtained from the air helix or propeller arranged with short blades of such width that the entire circumference of the propeller was covered.

This arrangement prevents inert air from passing through the propeller, and would normally be an ideal condition for screw action as applied to hydraulic propellers. Anemometer tests, however, proved that the air was driven from the propeller in a reducing stream at a velocity in excess of the calculated amount derived from blade pitch and rotational speed, while the approaching air was drawn in radially toward the propeller.

The results clearly indicate the reflecting action of air, due no doubt to its volumetric elasticity, and it would seem that further research should develop data of value not only in the design of propellers, but also in improving wing action, and possibly reducing head resistance of the stationary parts of the airplane.

J. C. Hunsaker[2] (written). Professor Brooks' statement in his introductory paragraph that "the accepted theory of air propulsion does not accord with the facts," is not substantiated in his paper.

The aerofoil theory as set forth by Lanchester and Drzewiecki, and now commonly used for the design of propellers, requires no assumption as to how an aerofoil element obtains its thrust, but bases the evaluation of this thrust on actual aerodynamic tests. Professor Brooks in his paper makes an issue of the fact that calculated and actual propeller performances do not agree. This may well be accounted for by the necessary approximations made in design regarding indraft and a lack of definite knowledge of the action of the air at propeller tips and hub.

[1] Director, United States Bureau of Standards.

[2] Naval Constructor, U. S. N., Bureau of Construction and Repairs, Washington, D. C.

Professor Brooks' reflection theory, while it need not conflict with the aerofoil theory, is open to criticism. The assumption is made that particles of air act as independent bodies and not as parts of viscous fluid, and that they rebound from the propeller blade without interfering with the surrounding air. Photographic investigation of the flow of air around models does not show that any rebounding action affects materially the shape of the stream lines. Moreover, a rebounding action from the surface of an aerofoil is not in accordance with Dr. Prandtl's elaborate experiments demonstrating the existence of "bounding layers," nor does it harmonize with the "vortex theory of sustentation" which has been verified photographically.

In the first paragraph of his paper Professor Brooks says that the theory of marine propulsion has been transferred to air propulsion without sufficient regard for the extreme difference in the two fluids as to elasticity. As previously stated, the design of a propeller is based on aerodynamic tests of the particular blade sections employed. Any effect that elasticity of air may have on air-propeller performance is accordingly taken care of in the choice of the proper blade section. There is extensive experimental proof that within certain limitations the same dynamic laws hold for water and for air. Perhaps the most striking example is afforded by a comparison of photographs of flow of air and water by models (Eden British Report No. 49). (In my paper given before the International Engineering Congress, 1915, I showed that the compressibility of air is mainly of theoretical interest.) A comparison of propeller tests made at the Navy Yard, Washington, with tests made by Dr. W. F. Durand, shows that there exists a close agreement between propellers tested in water and those tested in air and that it may be sufficient in particular cases to apply a correction only for the ratio of densities as the compressibility of air is not a serious factor. The important effect of viscosity was not considered in Professor Brooks' paper.

Regarding the conclusions drawn by Professor Brooks for static propeller tests, the following may be said:

No account was taken in his demonstration of "superspeed" for the acceleration of the air before coming in contact with the propeller blade. In consideration of tests made at the National Physical Laboratory and by Eiffel, Professor Brooks' theory does not seem to warrant the neglect of "indraft."

A prediction of full-flight performance from a single static test as suggested does not take into account the critical changes which occur in the thrust of a propeller, as the angle of attack of the blade varies, due to a change in the velocity of translation. It is not clear how a static test can foretell flying performance unless the aerodynamic properties of the particular blade are known.

M. B. Sellers[1] (written). When a propeller is constructed having zero pitch, that is, the face or driving side exactly parallel to the plane of rotation, and having the usual cambered back, it is found that this propeller exerts some thrust and delivers a considerable blast of air. Of course, there can be here no batting action, and yet we have a blast, due, in my opinion, to the fact that the rarefaction at the trailing edge on the back of the blade initiates an air stream. If now we try a similar propeller, but with an appreciable pitch, we find that the air stream now produced is approximately the sum of that due to the cambered back plus that due to the pitch. On the other hand, if we employ a propeller having a blade flat

[1] Member Naval Consulting Board of the United States, Baltimore, Md.

back and front, the velocity of the air stream, correctly measured, will about equal the geometric-pitch speed. It would seem to me, therefore, that the increased velocity of the air stream observed is not due to batting action, but to the effect of the rounded back of the blade.

LIEUT.-COL. J. G. VINCENT[1] (written). I have submitted this paper to our propeller expert, F. W. Caldwell, and have asked him to give me a brief report, which he has done as follows:

"We have had some correspondence with Professor Brooks in regard to his theory of propeller design. He seems to be working under the impression that we wish to produce a noiseless propeller regardless of its efficiency.

"The first model propeller submitted by Professor Brooks to the National Advisory Committee of Aeronautics showed an efficiency of only 38 per cent in contrast with a model of Professor Olmstead's which showed an efficiency of $89\frac{1}{2}$ per cent.

"Professor Brooks' paper is interesting from a theoretical standpoint, except that he seems to have drawn the wrong conclusion from his investigations. He seems to be under the impression that propellers with small diameters will produce good results, whereas all experience and all the usual propeller theories show that under most flying conditions the greater the diameter of the propeller, the better the efficiency obtained."

WALTER C. DURFEE (written). The most interesting explanation of superspeed as noted by Professor Brooks is in terms of the contraction of the jet or blast shown in his Fig. 3. It seems certain that the velocity of flow actually among the propeller blades cannot be great enough to drive the propeller any faster than it is being driven by the motor, unless the apparatus is acting as a windmill and the driving mechanism acting as a brake. The observed superspeed then is acquired immediately after passing the blades or may even exist to an extent at the blades, but in oblique directions. The contraction of the blast shown in Fig. 3 corresponds to a doubling of the speed of the propeller blast almost immediately after leaving the propeller.

An interesting explanation of this contraction and acceleration of the jet speed may be had without detriment to explanation in other terms by trying to study the action of the jet upon itself. The blast of a propeller of low pitch or of many blades is approximately a continuous jet or stream of variable cross section. To describe it we may use the language of vortex motion. It is the same jet in any language. At its center this jet contains a complicated system of vortex motion corresponding to the internal rotation of the jet and the comparative lack of motion along the central axis.

The outside surface or sheath of the propeller blast is the seat of a second vortex system which is mainly responsible for the velocity of the blast and for the annulment of rotation and velocity in external regions. This outer system, which mainly determines the velocity of the jet, coils like a helix around the blast, with its origin at the propeller tips, much like the two serpents which coil about the "caduceus" or winged wand of Hermes, their two heads beneath the wings. Imagine these two serpents or snakes to grow interminably, continually fed from the propeller blades and their bodies rolling along as vortices between the jet and the outer air. Imagine too that every particle of moving air is the servant of these serpents and that the serpents themselves writhe with a motion exactly determined by the influence of all the neighboring coils. The result is a simple example in turbulent motion. The exact calculation of the motion of the serpents or vortices is not without importance if it can be accomplished. The thrust of the propeller, for example, depends on its angle of attack against the relative wind, and this relative wind is the abject slave of the serpents or vortices which feed on the propeller.

For the purpose of studying the reason for the contraction of the jet as mentioned by the author we may imagine that the jet is momentarily made straight and uniform like a pipe, i. e., uniform vortex coils from end to end. Under these conditions there is a collapsing motion at the entrance or beginning of the jet because the motion of the air here is due to the vortices immediately in front which roll inward as viewed from the propeller. The velocity also in the supposed straight-walled blast may be studied. A forward component is provided by all the vortex coils. Within the tube the in uenee of these is felt both in the front and in the rear of any point, so the velocity is greater inside than at the entrance to the tube where the influence is only in front. On the whole, the action of the jet upon itself is in favor of a contraction near the origin, and in favor of somewhat slower motion at the entrance than at a point a little within the jet.

If we could persuade a professional mathematician to "bell the cat" for us it would indeed be a splendid achievement to become able to calculate superspeed as Professor Brooks has suggested will some day happen. Until we can get the exact formulæ which he foresees, I think we should congratulate him very heartily on providing us with useful data on the subject of superspeed.

Mr. Durfee prefaced the presentation of his written discussion by saying that he wanted to defend Professor Brooks' ideas, and to do this the simplest way was to explain practically all the nine different theories of the action of the air going round a blade of a propeller. These theories were: The Screw, Bat, Vacuum, Stream-Deflection, Momentum, Hydraulic, Purely Mathematical (with variations), Impulse, or Side-Pressure, and Vortex, or Whirlwind theories.

The screw theory assumed that air is very nearly solid, on account of its inertia. The propeller was assumed to screw through it as if it were a block of wood. Next the additional

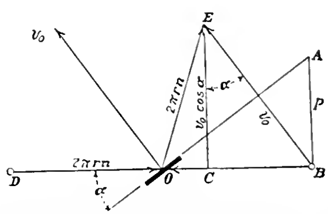

FIG. 9 DIAGRAM ILLUSTRATING TEST CONDITIONS FOR A WIDE-BLADE PROPELLER (BLADE ANGLE $\alpha = 36$ DEG.)

assumption was made that the air is not solid, that it has some slip. This we knew from experience.

The bat theory took account of the motion of the air after it left the blade, and if Fig 9 (Fig. 1 of the paper) were examined, it would be seen that the author had shown the reaction against the blade as perpendicular to the surface. It did not make much difference whether it was a baseball, or a sand blast, or a stream of air; there was not much friction to that surface and the reaction was substantially normal to the

[1] Chief Engineer, Airplane Engineering Dept., Signal Corps, U. S. A.

surface. It had to be. It would also be noticed that the velocity DO branched off and became motion OE. In other words, the stream of air did not lose much energy as it went past, and as far as the mathematics showed, he saw no difference whether it was a baseball or a sand blast or a stream of air. There was not much energy lost; the reaction had to be in about the same direction. He thought the origin of the criticism of Professor Brooks' theory was the feeling that if air consisted of a number of particles they could not all come down to the surface and go back to the same space. There could not be two directions in the same place.

The vacuum theory was based on experiments which showed that the partial vacuum on the top of the wing was numerically larger than the positive pressure underneath the wing. The difference in pressure held the wing up. It was not the vacuum, it was not the pressure; but it was the difference between the pressure below and the vacuum above.

The stream-deflection theory assumed that a stream or layer of the air came along and struck the inclined plane, i. e., the propeller blade, and was thus deflected. The question was: What supplied that force? The trouble with the theory was that one had to decide how big was that stream. The active stream merged into the surrounding air, and it was necessary to assume a stream and guess its proportions and how it was deflected.

Exponents of the momentum theory said, "Never mind what happens around it. If the air strikes against the blade, the air is going down behind it; how fast it is going down is told by the slope of the blade." They calculated the weight of air and how fast the blade was going down with the weight, how much impulse must have been supplied to produce that motion, and they obtained a result.

What he called the hydraulic theory of this sustentation was this: Where the water was going fast through a venturi tube there was a low pressure; where it was going slow there was a high pressure. With a thick wing such as the author mentioned, one could readily imagine that the air went a little faster over the top than over the bottom. Therefore, from the simple theory of hydraulics one could calculate where the pressure was low and where it was high. This pressure difference lifted the wing. The hydraulic theory had advantages when one was calculating the action of a propeller in a pipe. The ordinary theories could not be used as in the open where the air was supposed to stand still and be hit; the back pressures, etc., must be considered.

The mathematical theory assumed a perfect fluid: Find what a perfect fluid would do and thus learn what a real fluid would do. Lord Kelviu had said: "Here is what a perfect ı uid will do. My guess is that if the air had a little bit of elasticity or a little bit of viscosity this action would not occur and a totally different action would take place." Then he proceeded to tell what it would be.

H. F. Hagen said that the screw theory as mentioned in the paper, with the idea that a screw went through a solid mass either in air or water, had never been used by any designer or scientist. As originally presented by Rankine, it allowed for a certain slip. The term slip, however, was rather unfortunate. We were accustomed to say that a propeller could not do any work unless it had a certain slip, but it would be much better to say that a propeller could do no work unless it had produced rotation in the direction of the rotation of the screw. That had been proved by a number of investigators and to disregard it would be entirely incorrect.

The vacuum, stream-deflection, momentum, hydraulic and mathematical theories enumerated by Mr. Durfee he thought could all be combined under the term "stream-line theory." Professor Brooks' theory did not take account of the discharge side of the propeller, and as the speed of the fluid on the discharge side was certainly faster than the speed of the fluid entering, there could be no continuity. That would require water to be broken up into droplets, or air to behave like a cloud of non-interfering dust particles. The chief objection to this was that air or any other fluid did not work that way. Any one who had ever observed the flow of smoke around the blade would have noticed that there was only one stream line really that touched the blade—the others were formed flowing around smoothly.

Any propeller theory to be complete ought to explain both the action in air and water. Both were fluids and the difference between them was not one of elasticity but of compressibility. Air was compressible, water practically non-compressible. Making due allowance for compressibility, density and viscosity it should be possible to predict the performance of the air propeller from that of the water propeller. There were questions as to the latter regarding the shape of the stern of the vessel, the free surface of the water, and the bottom, which all combined, so that although the general theory might bring the two together and reconcile the airplane propeller and the water propeller, he doubted very much whether tests on water propellers could ever be used for air propellers, because although the stream lines might be similar, yet it would be impossible to transfer any quantitative results from one to the other.

Mr. Hagen then entered into the discussion of the air-propulsion theory propounded by Rateau, which, he said, was about the most satisfactory one that had been presented. Owing to time limitations, however, he was unable to complete his remarks but promised to present them later in writing.

A FOUNDRY COST AND ACCOUNTING SYSTEM

Discussion of Paper by Prof. W. W. Bird

In Professor Bird's paper a foundry cost and accounting system was outlined which has been developed as a result of experiments carried on in the commercial foundry at the Worcester Polytechnic Institute. The system, the author stated, is giving good satisfaction and has been found to be thoroughly reliable as a signal system. It is based on the principle that the three most important items of cost are core labor, molding labor and pounds of castings produced, and that each of the other items of cost is a function of one of these. All of the work involved can be done by the regular clerical force of the foundry in a small amount of extra time.

Written discussions of the paper were presented by Benj. D. Fuller, R. S. Denham, R. E. Newcomb and M. J. House, and it was orally commented upon by Dr. R. Moldenke, Malcolm Libby, Wm. L. Walker and William Kent. These discussions are given below.

Benj. D. Fuller[1] (written). The cost system presented by the author is in the right direction and probably satisfactory as an accounting guide for a foundry such as the one where it has been applied; but in my estimation it does not go deep enough to be thoroughly successful in accounting for the costs of a large concern. Too little attention is paid

[1]President, American Foundrymen's Association.

to the question of overhead distribution, which is a very important factor.

Overhead is in some cost systems carried entirely as a percentage on direct labor cost; in others as a percentage added to poundage or weight. A more equitable distribution is to divide, carrying a percentage on labor and another percentage on weight. Some castings require an excess of labor for a minimum of weight, in which case the labor overhead would be the larger in the accounting, and justly so. But imagine a casting of excessive weight and a minimum amount of labor, such as a large floor plate cast in open sand. Here the weight basis of overhead would, in accounting, rightly carry the bulk of load.

Cost systems giving individual casting costs are much more valuable than those where the output is handled in bulk or weight classifications.

In the third paragraph of the paper it is stated that "the three most important items were core labor, molding labor, and pounds of castings produced." To these should be added cleaning labor, which varies widely in cost with the class of work.

The fifth paragraph says that in the general scheme used an account is charged with the amount of the purchases made during the month. Payroll charges in connection should not be forgotten.

In the sixth paragraph it is said that "All expenses are charged to the Expense Account." There should be subaccounts for the various classes of expense to care properly for these charges.

The items Core Work, Molding, and Metal and Melting which the author uses in his records, should each carry a share of building repairs, light, heat, depreciation, insurance, taxes, administration, etc.

ROBERT S. DENHAM[1] (written). Product of whatever kind, consists of materials and the time of formative processes. In this paper the material is Metal, and the formative processes are Core Making, Molding, and Melting.

By analysis we find that the handling of materials or metal involves the expenses of transportation, handling labor, rent of stock yard or room, interest and insurance on investment in material, shrinkage, etc.

Analysis of the formative processes will show that each requires more or less of the following expenses: Rent, heat, building repairs; depreciation, interest, insurance and taxes on equipment, power, light, water, ice, compensation insurance, supplies, repairs to equipment; wages of workmen, etc.

Administration and selling expenses include salaries, advertising, office supplies, telephones, bad accounts and collection expenses, discounts, commissions, etc.

Further, there must be consideration of the expenses of packing and delivering the product to the local consumer or freight house.

Professor Bird arbitrarily selects the process of core making and charges it with the expenses of wages and supplies, the latter being charged on the basis of 30 cents to each dollar of wages paid to coremakers. None of the other expenses is considered in connection with core making.

He then burdens the molding with all of the other expenses of the business, including all of the operating and administrative expenses required by the core making and melting except an unexplained charge of 30 cents per 100 lb. on the melting process. His basis for the charge of this mass of unrelated items is the wages of the molders.

[1]Consulting Cost Engineer, Cleveland, Ohio.

For some reason, also unexplained, he selects the items of supplies from the mass and charges for these at the rate of 6 per cent, while what he calls "Expense" is charged at the rate of 75 per cent on the wages of molders. Since both have the same basis in his plan the same result would be obtained by a single charge of 81 per cent.

A practical degree of exactness is essential in a matter as vital as the cost of production, and the writer holds the following principles to be fundamental:

1 The cost of an item of product is the sum of the expenses involved in its production and distribution up to the moment at which cost is determined.

2 Every cost element (expense item) is definite in amount, and purpose, and anticipates a beneficial equivalent in service or commodity.

3 In the distribution or charging of expenses consideration should be given to the benefit derived that the charges may be justly assessed where the benefit is conferred and in true proportion to the measure of benefit.

If each of the above-mentioned items of expense be now considered it will be found that not one of them bears a relation to wages such that the benefit conferred by the expenditure increases or decreases with fluctuation in wages, or as between the product of men receiving different rates of wages. Neither is there a relation between the wages paid and the total of these items applicable to the product of the workmen.

No scheme of cost accounting which involves the distribution of a mass of expenses under the title of "overhead" or "burden" will bear analysis. The correct determination of cost of product can be accomplished only through the comparatively new analytical method known as Cost Engineering, in which each process is considered separately and each item of expense individually applied by measurement so that expense and benefit are in identical proportions, making it impossible for one process to carry any of the e pense belonging to another.

ROBERT E. NEWCOMB (written). It is axiomatic that in the management of any business, facts, not surmises, must form the basis for operating.

While the costs of core materials, molding materials, expense and melting may be functions respectively of the core labor, molding labor and pounds of castings produced, they are at the same time variable functions and hence, basically, surmises which cannot form an accurate basis for operating.

The object of cost accounting is to establish and fix profits, and a cost system should strive to get the absolute facts and figures. To arrive at proper cost, the following well-established formulæ must be used:

Cost of Material + Direct Labor = Prime Cost
Prime Cost + Direct Factory Expense = Factory Cost
Factory Cost + General Expense = Cost to Make
Cost to Make + Selling Expense = Cost to Make and Sell

and in foundry cost accounting it is essential that the cost be built up from the following items representing the total of accumulated details: Core Labor, Supplies, Mold Labor, Chipping Labor, Miscellaneous Labor, Melting, New Metal, Scrap, Other Expense, each item in sum total.

The accumulated details should be obtained from the record of the actual number of units of material used from day to day and the actual number of hours of labor. The cost of material delivered during a current cost month should not be used as a basis of establishing costs, as is apparently suggested by the author, as it would not give a true cost for the

reason that the material entering the castings, especially in a foundry carrying a stock of iron, may have been delivered at a price differing considerably from the cost for the current month. This difference in price may make a considerable fluctuation in the selling price, which would apparently cause the foundry using this method to quote both low and high prices at the wrong time. A better method would be to average the cost of the pig iron and material in stock, preventing fluctuation in apparent cost and selling price.

As a signal system to indicate the drift of the cost, a daily estimate may be made based as follows, assuming a specific case for illustration:

Let M = total number of men = 175
T = total melt in tons = 35
P = average proportion of good castings in melt = 0.7
L = average cost of labor per man-hour = \$4
I = average cost of metal at ladle per ton of good castings = \$25
S = average cost of supplies per ton of good castings = \$10
m = average men per ton of good castings
$= M/(T \times P) = 175/(35 \times 0.7) = 7.10$
l = average labor cost per ton of good castings = $m \times L = 7.10 \times 4 = \$28.40$
C = total cost per ton of good castings
$= l + I + S = \$28.40 + \$25.00 + \$10.00 = \$63.40$

The above figures are actual or based upon the previous month's accurately established costs, and from day to day are reasonably reliable signals indicating to the live foundryman the drift of the cost for the current month; and in the respect that they are available from day to day corrective measures may be taken to reduce greatly increasing costs before having run to a disastrous extent.

M. J. House[1] submitted an extended written discussion of the paper, in which he indicated wherein it appeared to him that the author's plan failed to provide adequately for cost and accounting requirements under the ordinary conditions of a commercial foundry.

While not doubting in the least that, as stated, the system was giving excellent satisfaction, that the data it kept before the foundry officials were thoroughly reliable according to the plan and that clerical work required but little extra time, it did not follow that the costs were "fairly accurate." Numerous systems were in use which fully satisfied those who used them and, in many plants, statistical data of great importance were compiled, yet the costs obtained were far from dependable.

In the third paragraph the author set up three independent variables, namely, Core Labor, Molding Labor and Pounds of Castings Produced, as the most important ones and considered all other items of cost as "functions" of some one of these.

As a general proposition, however, there were seven variables equally important, owing to their direct influence on costs although not in like proportions. These seven were Pattern Labor, Core Labor, Molding Labor, Melting Labor, Cleaning Department Labor, Materials and Supplies and Pounds of Castings Produced. Like a majority of founders, the author ignored the fact that labor employed in the pattern shop was directly related to production, was chargeable directly to jobs or classes and was not an item to be prorated over production as a whole if of consequence; there was no more reason for doing so than for the diffusion of Molding Labor in the same way.

The difficulty referred to in respect to split payrolls, Mr. House believed, was more imaginary than real; as, if accounting classification was properly devised and followed, the manufacturing accounts might be tied in with financial records without use of split payrolls and the twelve cycles for comparison annually might consist of two periods of four weeks and one of five weeks each three months.

He was not prepared to dispute the statement that the cost of melting varied directly with pounds of castings produced, but unless the quantities of the several patterns cast were identical each month, he was at a loss to understand how such a result could be achieved, as the cost of melting actually varied according to quantities of gates, sprues, defectives, over-metal etc. Unless the product was practically uniform from month to month, the melting credit could not possibly parallel the production.

Mr. House then outlined a cost accounting plan that he had found to be very simple, highly accurate and easy of application. In it melting and departmental expense rates were predetermined, all expense was concentrated into six rates and—when cost computations were made—which might be at any time a lot of castings was finished, the only factors to be dealt with to obtain Shop Cost were Metal and Castings, Direct Materials, Direct Labor, Departmental Rates and—sometimes—special costs in the form of patterns, flasks or other special rigging.

R. Moldenke. I find that Professor Bird's work, while of an extremely varied character, is still a work which is a continued operation. His cores and molds are about the same all the time; there may be large castings and small castings and varied work, but they repeat themselves to an extent that will allow him to draw his conclusions. This system is good for his work but may not be fit for different work, and these discussions fall back on the fact that they want more exact cost where the work varies, whether there are few castings or many castings. The pilot-light system is a good one when applied to current practice. We want to know costs as exactly as we can get them. There comes a time when it may be good to get some percentage division, particularly of the overhead in the nature of the work. For instance, few shops differentiate from the ordinary floor plate of the engine bed or light casting. It is important that they should do so because the overhead should be differently distributed from one class of work to another. It may be found that line work is produced at large cost but small profit. There should be a division of the work into classes. Then comes the system of Professor Bird to distribute the overhead, particularly after some of the fundamental costs on the different classes are known, to show which line of work should be continued. I like the paper because it attempts to give a method of finding a system which will tell quickly whether one is making or losing money.

Malcolm Libby. It is to be hoped that Professor Bird will present at an early date this question of prices and bids because it would make clear many of the points of the paper, and in the discussion especially so, inasmuch as the judgment which is made on the foundryman, i. e., the superintendent's efficiency and capability, involves several factors. He mentioned an all-important one, namely, the selling price turned immediately back to production. Some companies are in a fortunate position in that they are able to establish the market price. Their cost systems must involve the principle which covers the ques-

[1] With C. E. Knoeppel & Co., New York City.

tion of determining the price quite as much as determining the costs.

William L. Walker. The idea of connecting the cost-accounting system with the accounting department, and being sure that in the costs in the foundry all the expenses found in the account books are so used, is important. Many plants have cost-accounts systems based upon the estimated account. The costs are never carried into finance the books closed, but at the end of each year there appears a large balance of unabsorbed expense. In Professor Bird's foundry the work likely goes along about the same, and the element of error entering into the factor of indirect overhead expense would not be as great as in a large foundry producing many items where there are different kinds of furnaces, of molding machines, and of departments. It is necessary to distribute the overhead expense by departments, by various types of operation, and put it there as an indirect cost, allowing for space cost, building depreciation, insurance, taxes, repairs, and other items entering into the expense. By a system of classification of expense these items may be put in the account records. In any cost system we can not get absolute accuracy—it is impossible. Costs can be put on in a manner that will show the results as nearly accurate as it is practical to go, i. e., to where it does not cost more to get the cost than the actual difference in the method involved.

William Kent. For the purposes of this particular foundry this system may give a close enough approximation to what Professor Bird wants to get; but I agree with the speakers who have preceded me in saying that the system will not do for any foundry operated on different kinds of products, and that some other system must be used. The objection to his method is that he uses factors and percentages. Generally speaking, averages and percentages and factors should be avoided. What we want is items summed up into totals and these totals put into proper reports, and if possible charted so that we can see how things are going. The idea of using an accounting system as a signal is good. The best signal is found not in an accounting system, but in the reports of tonnages and other items that are put in a table of monthly averages. The discussion will contribute largely to the value of the paper.

The Author. I do not believe in the cost system. If you want to see how our system works, go to our office. If those who criticize this paper can show a system comparable with ours in regard to the cost of keeping this system, I challenge them to bring it along. Our bookkeeper runs off this balance sheet, and he does not know anything about the foundry business, yet when the trial balance is made up we have our result. There is no other system that will give anything like that. I have made a study of the foundry business; I am president of the Broadway Iron Foundry, Cambridge, Mass., where we have used the system fifteen or twenty years. It is not a question of cost. We want to know if we are making money. This paper describes a cost-of-account system. This is a cost system based, or which starts, if you will, on the top of a pyramid. All the cost systems I have ever seen start at the foundation. We start at the very top. How much did you make last month? We have it immediately. I am glad one of the speakers pointed out that it is essential that costs should be tied up with the accounting system. That is seldom done. Some one asked why we did not put something in about labor. We consider that we purchase our labor; the labor is in the purchases. Understand, the paper deals with a cost-of-account system, not a cost system.

AN INVESTIGATION OF THE FUEL PROBLEM OF THE MIDDLE WEST

Discussion of Paper by A. A. Potter

In this paper the author showed by figures received from numerous power plants in the Middle West that their increased cost of producing power during the past winter was due to: *a* The increased cost of fuel; *b* The necessity of burning fuels of different grades with equipment suitable for one particular grade; *c* The greater amount of ash and other non-combustible matter; *d* The increased cost of labor and the poorer quality of labor available; *e* The increased cost of repairs, supplies and new equipment.

He then discussed the effect of increased expenses and fuel scarcity on isolated plants, detailed the various efforts which have been made to obtain better fuel economy, and outlined the work accomplished by the Fuel Administration Boards of Iowa, Louisiana and Illinois.

His conclusions were that future emergencies in the Middle West plants could be averted by more adequate fuel storage, by greater attention to fuel economy, and by the more careful regulation on the part of the Government of the quality of fuel leaving the mines and of the fuel-transportation facilities.

Written discussions embodying pertinent comment were contributed by Alex. D. Bailey, John D. Riggs and E. A. Uehling, and are as follows:

Alex. D. Bailey (written). Referring to the second paragraph of the author's conclusions, the cost of $15 per ton capacity for subaqueous coal storage pits might be very discouraging to anyone considering for the first time the storage of coal, as under ordinary methods of figuring fixed charges this would mean an annual cost of at least $2 per ton for the coal-storage equipment, exclusive of handling. Using locomotive cranes for handling coal into and out of open coal piles on the ground, approximately 10,000 tons per acre can be stored, and the depreciation due to weathering would be negligible compared with the cost of subaqueous storage plants.

By storing only screened or washed coal the danger from spontaneous combustion is reduced to a minimum; further, it is advisable to store the best coal obtainable, as in this way the maximum heat value is obtained per dollar invested in land and coal-storage equipment as well as in the coal itself. This applies also to the cost of handling, as good coal can be handled as cheaply as poor coal, both into and from storage, as well as in the boiler room, and as this storage is generally used under emergency conditions, when weather conditions are unfavorable, and when not only the coal-handling equipment but the operators are taxed to their utmost, the maximum return is assured for each ton of coal handled.

It should be borne in mind also that storage coal is generally required during extremely cold weather when shipping facilities are hampered and when everything is badly frozen. For this reason precautions should be taken to keep the storage as dry as possible to facilitate handling, as it can be readily seen that coal which is flooded in a storage pit, and frozen solid, will be unobtainable when needed most.

John D. Riggs (written). In regard to proper furnace design for small one-boiler plants using high-volatile coal, it has been observed that the combustion chamber is usually too small when working near full capacity, but ample at half load or less. This trouble may be partly overcome by having a rather large grate area, and bricking over a portion of it.

when working light. It would seem that better arrangements might be provided for lowering the grates and bridge wall in the fall, and for raising in the spring of the year, or when the load is to be light for a time. We think it is quite common practice with men accustomed to such coals to use a thin fire, and not attempt to crowd the boiler. With some other bituminous coals, especially the "dry-burning," we have noted the use of smaller grate surfaces, much thicker fire bed, higher chimneys, and a tendency to crowd every working boiler to the limit, even where a plant has several extra boilers.

During the past winter some householders had to burn bituminous coal of one class for a period of perhaps twelve days, then change to another class for a similar period, and then change again, until when spring finally came, we found that about six varieties of fuel had been used, some bearing unfamiliar names, and one lot with no name at all. The net result of this may be estimated as 30 per cent extra coal on account of an unusual winter, and another 30 per cent extra on account of unusual conditions, beyond control.

Now comes the slogan, "Buy Your Fuel Early." This is common practice for the man who heats with coke or anthracite, but not at all for the one who uses many of the western bituminous coals, and even dangerous practice to some men who have often seen an outside coal pile at a power plant on fire. Such fires seldom do much damage at the power plant, but may lead to the destruction of a home.

E. A. Uehling (written). Early in the paper the author says: "Suggestions have been made by power-plant engineers that the Fuel Administration should regulate the supplies from the different mines in such a manner that individual plants would get their supply of uniform grade." This would be a wise procedure if it could be carried out, but in the case of acute fuel shortage, when whatever is available must be taken, it will not work out. The Government's zoning proposition if properly carried through should operate in favor of this suggestion.

It goes without saying that it is more difficult to burn heterogeneous mixtures of coal efficiently than coal of a uniform grade; but even the most uniform grades of coal are liable to vary appreciably in their ash and moisture content as well in the ratio of coarse to fine, and will not run over the grates uniformly with the same stoker speed, and the air supply will therefore require frequent readjustments at best. The proper slogan for the engine room should be: *Watch your adjustments and keep them right and your results will be right,* but that for the boiler room must be: *Watch your results and change your adjustments to keep them right,* if attainable efficiency is to be achieved and maintained. There is no such a thing as fixed adjustments in the economic operation of steam boilers. Automatic adjusting devices do not and cannot produce maximum economic results.

The steam gage is the monitor of the boiler room. Combustion must be increased or decreased as its hand points below or above the standard pressure. The steam-flow meter indicates whether the boiler responds to the accelerated or slackened steam production dictated by the steam gage; neither gives any information as to whether the fuel is being burned economically or wastefully; but unless this information is continuously before the fireman, he is working in the dark, and the highest economy attainable under the prevailing operating conditions cannot regularly result.

The percentage of CO_2 in the products of combustion is a true index to combustion efficiency. It is a correct measure of the excess air supplied and the continuous CO_2 indicator at or near the boiler front is the only practical means by which the fireman can tell with any degree of certainty whether his draft is properly adjusted to meet the variable combustion requirements economically. I hold that a fireman can operate a given boiler equipped with a continuous CO_2 meter to guide him more economically, burning coal of variable grade and composition (within reasonable limits), than he can with coal of a normally even grade without such a guide.

Mr. Potter cites many instances where coal of abnormally high ash content was foisted upon helpless consumers during the fall and winter of 1917-1918 by unscrupulous coal operators, the coal in some cases carrying from three to si: times its normal ash content. "In general," he says, "the ash content in the fuel used during 1917-1918 was at least 5 per cent greater than in former years, due to faulty methods at the mines."

When we consider how intensely the shortage of coal required by the industries was aggravated by the e cessive ash and slate contents of the coal, and that the shortage was not due to lack of miners or mining facilities but to car shortage and transportation overburdened by something like fifty million tons of slate and the ten to twenty million tons of coal required to melt it into clinker-obstructing boiler operations, we should not let this catastrophe pass over by merely stating that it was due to "faulty methods at the mines."

When we further consider the retarding effect on the production and shipment of most vital and urgently necessary war supplies, the damage done to the industries of this country in general, and last but not least, the intense suffering caused to millions of poor and even many well-to-do people, I think the "faulty methods" should be stigmatized as nothing short of criminal profiteering, in comparison to which the notorious embalmed-beef scandal of our misconducted Spanish war was an insignificant episode.

Upon the recommendation of its technical committee the Compressed Air Society has adopted the following definitions of certain terms in order to eliminate confusion as to their exact meaning.

Displacement. The displacement of an air compressor is the volume displaced by the net area of the compressor piston.

Capacity. The capacity should be expressed in cubic feet per minute and is the actual amount of air compressed and delivered, expressed in free air at intake temperature and at the pressure of dry air at the suction.

Volumetric Efficiency. Volumetric efficiency is the ratio of the capacity to the displacement of the compressor, all as defined above.

Compression Efficiency. Compression efficiency is the ratio of the work required to compress isothermally all the air delivered by an air compressor to the work actually done within the compressor cylinder as shown by indicator cards, and may be expressed as the product of the volumetric efficiency, the intake pressure and the hyperbolic logarithm of the ratio of compression, all divided by the indicated mean effective pressure within the air cylinder or cylinders.

Mechanical Efficiency. Mechanical efficiency is the ratio of the air indicated horsepower to the steam indicated horsepower in the case of a steam-driven, and to the brake horsepower in the case of a power-driven, machine.

Overall Efficiency. Overall efficiency is the product of the compression efficiency and the mechanical efficiency.

The Society further recommends that the use of other expressions of efficiency be discontinued.

ECONOMIES IN MANUFACTURING IN THE CANNING INDUSTRY

By J. H. Shrader,[1] Washington, D. C.

This paper, which was presented at a meeting of the Baltimore Section on March 12, 1918, outlines the general procedure followed in tomato canning and points out the numerous sources of loss. The manufacture of concentrated tomato products is described and in particular that of tomato paste, a seedless and coreless food product which, compared with ordinary canned tomatoes, cuts down the fruit waste from 50 per cent to 5 per cent, requires much less labor in its preparation, saves two-thirds of the expenditure for tin plate and greatly reduces shipping costs.

At the same meeting a paper entitled Investigation of the Uses of Steam in the Canning Industry was presented by Prof. Julian C. Smallwood, of Johns Hopkins University, which was again presented at the Spring Meeting of the Society in Worcester and printed substantially in full in the May issue of The Journal. In this paper Professor Smallwood analyzed the different heat processes employed in the canning of food, described the various forms of apparatus used, and pointed out actual and ideal steam consumptions and methods of minimizing waste. The two papers taken together form a valuable survey of the present technical status of this important food-preserving industry.

When one interests himself in the manufacturing aspect of the great steel industry, he finds the whole procedure made up of a number of more or less isolated processes each complete in itself but contributing its share to the completion of the whole. He sees machinery everywhere and most intimately connected with the whole process of steel manufacture from extracting the iron from the ore to turning out the finished goods. As perfect as the whole operation seems, the intelligent investigator will not be surprised when told that the technologists operating the plant can point out most serious deficiencies in many places, and that the whole staff is continually striving for improvements. One also expects to find great technical developments in the copper industry. Large engineering and chemical staffs are employed to devote all their time to surmounting difficulties and controlling operations. In these great industries we expect complexity and its attendant problems.

But when one considers such industries as that of canning, he naturally wonders where there might be any difficulties of moment, and where there can be the need for much mechanical application. Surely, if the activities of our wives and mothers during the canning season are any criterion, the whole procedure seems simple enough. So seems the iron industry when one seeks to make 5 lb. of iron in a day or two, with a whole forest back of him for charcoal and no time factor to be troubled with. It was the economic pressure of quantity against time that forced the ironmasters from counting pounds to counting tons. The same conditions forced food manufacturing likewise from the pound basis to that of tons. But the necessity of this capacity consideration is only the first of a number of problems. If the ironmaster unexpectedly has an extra lot of ore dumped at his plant, or if his plant shuts down for any reason, the iron ore can be readily stored until such time as the superintendent calls for it. His operating season is the whole year.

The canner, however, figures on a brief season of a few months of intensive effort in which he has to make whatever he can and then close up and wait three-quarters of a year until the next season. Consequently he plans to keep his plant running nearly to capacity while the running is good. Any unexpected glut of raw material together with factory shutdowns always accompanying capacity stride means a slip somewhere—either a loss due to inefficient operation or spoilage, or both, for raw food products can not be readily stored but begin to spoil before they are well on their way to the factory. It means get them into cans at once or lose them.

The operation of commercial canning consists of the following steps, and in general applies to about all the fruits and vegetables used:

1 Preparation of the material for canning, such as sorting out the spoiled, washing and trimming
2 Packing into cans, either by hand or machine
3 Adding the necessary juice, likewise by hand or machine
4 Exhausting, or reducing the pressure within the can
5 Sealing either by the old method of soldering the top or by the new so-called sanitary method by which the top is pneumatically crimped on to the can
6 Sterilizing by heat in continuous or non-continuous retorts: and
7 Inspecting the cans for imperfect sealing, then labeling, boxing and shipping.

Procedure Followed in Tomato Canning

As applied to tomato canning, the above procedure operates as follows: Tomatoes in the Tri-State District (Maryland, Delaware, New Jersey) are usually shipped either by boat, car or wagon in what is known as the ⅝-bu. basket, stacked, and piled several high at the destination. About the only advantage this method of shipping possesses is that the baskets are easily handled, are light and when stacked afford ventilation through the pile, thus reducing the inevitable spoilage to a minimum.

The tomatoes are then dumped into a scalder at the rate of about twenty baskets per minute, more or less, according to size and condition of tomatoes and rate at which they are used by peelers. This machine washes the fruit and by means of a continuous chain belt carries it through a jet of live steam, then quickly under a curtain of cold water. The short duration of the steam application localizes the heat mostly at the skin, while the sudden bath in comparatively cold water cracks the skin, thus rendering the latter easy to be removed. The procedure from here differs somewhat, but the essential point is that the scalded fruit is then dumped from the scalder belt into shallow pans or other receptacles which travel along a table provided with a moving belt about which are stationed the women who peel. As the latter are in need of tomatoes they slide the basket or pan of tomatoes from the moving belt on to a small shelf in front of them, peel the tomatoes over a trough or pan, and place the peeled fruit into a bucket. Sometimes tomatoes are brought to them and dumped into a stationary receptacle out of which the peeling is done. When the bucket of peeled tomatoes is full, the peeler is paid on the spot and is directed to place her bucket of tomatoes on the same or another belt, according to the system used. The peeled tomatoes are thus carried to the filling machines. In some factories the tomatoes are placed on a long table around which stand the girls who pack them into the cans by weight. In other cases the tomatoes are dumped into filling machines set to deliver a so-called constant quantity of the fruit into cans automatically placed to receive it, and in the same way carried away when filled.

[1] Chemical Technologist, Bureau of Plant Industry, Drug and Poisonous Plant Investigations.

The cans containing solid, comparatively speaking dry or drained tomatoes are then delivered to belts which convey them to machines where they are filled with tomato juice even with the top. This juice is collected from the receptacles of tomatoes, for after peeling the fruit loses juice continually all along the line until canned. Then the cans pass into the exhaust box.

The object of exhausting is to heat the contents of the can to a slightly elevated temperature so that when capped and cooled to atmospheric temperature the contraction of the contents causes a slight diminution in pressure. This is called exhausting. This heating is effected by live-steam jets and may last several minutes, depending upon the condition of the fruit, duration of contact, intensity of heating and quality sought.

From this box the cans are capped. If the old soldering process is used, the cans pass under a machine which washes off the top. A cap is placed over the hole by a girl and is soldered either by hand or by a machine. In the newer or so-called sanitary method the can passes directly from the exhaust box to the closing machine which sets the top on and crimps it pneumatically to the flange of the can.

Since tomatoes may be sterilized by heating to either 212 deg. fahr. for, say, 30 min., or 240 deg. for 10 min., it follows that in the first case an open tank of boiling water is sufficient, while in the latter event a closed retort similar to the autoclave of the bacteriological laboratory may be used.

After this treatment, called processing, the goods are stacked on the floor long enough to enable all faulty cans to manifest themselves, which they do in a manner never to be forgotten by any one who ever passes through a factory where they are stored! They are then labeled by hand or machine, boxed and shipped.

Sources of Loss in Tomato Packing

All of this sounds as if the packer's whole effort is to start the operation and all will then go well. The starting is the easiest of all. To maintain the pace and yet pack with a minimum of waste and lost motion is the important problem. Great as have been the strides in developing the art of canning, we have not half covered the ground from the standpoint of avoiding waste of material, not to mention the almost criminal waste of heat.

If the pack represents 50 per cent of the weight of the original raw stock, the packer congratulates himself on the successful yield. Sometimes it yields 65 per cent. Often it is down in the thirties. This means that if we take a 50 per cent yield as our basis, in Maryland we lose 71,000,000 cans or over $2,000,000 at $15 per ton of raw tomatoes, and in the United States 785,000,000 cans, or nearly $5,500,000.

The first place where good engineering practice is necessary is in the devising of an efficient sorting table. This is the tomato conveyor belt along the sides of which stand the women who pick out the unsound material. The object sought is a procedure whereby the unsound fruit can be detected without picking up each individual tomato to inspect the condition of the underside, and at the same time too rough treatment of the delicate fruit be avoided. Since much of the fruit is very ripe and all of it very juicy, any rough treatment will crack it, resulting in loss of juice and deterioration of quality. Efficient sorting consists in inspection of the whole tomato with ready means of removal and disposal of the unsound ones. Machines which rotate the tomato tend to crush the soft goods; spraying machines with strong sprays designed to dig out the decayed portions of the fruit, operate to destroy sound but at the same time very ripe stock; while plane belts equipped with ridges over which the tomatoes will tumble either do not work in a jam or contribute to shrinkage by cracking soft fruit.

The greatest actual loss occurs in the operation of peeling. Now give a woman time and she can doubtless peel a tomato with but little loss over that naturally expected due to core and juice. But if she is doing piece work and is paid by the basket, is not charged with the raw material and does not pay for the waste, then she ruthlessly cuts away much of the tomato in her haste and the packer pays double.

A 50 per cent yield is fair and one of 65 per cent extraordinary. The rest is absolute waste. The solid part is hauled away at a net loss; the juice, containing as much food and condiment value as the so-called solid portions, flows into the sewer. And we cry, "Increase the tomato acreage."

Another source of loss is the tomato filling machine. Imagine the effect on a tomato when it is forced up into a cylinder closed at one end by a piston and discharged through the small top into the can by the descending piston. To say the least the tomato is badly torn and the valuable juice flows away. Other types of fillers exist but each has its serious objections; most all of them not only tear the fruit more or less, but give unequal fills of the so-called solid matter by their inability to prevent the liquid portions from settling to the bottom of the hopper and leaving the upper ones dry. This is largely why the housewife complains that often she opens a can and finds it mostly juice with here and there a lonely piece of tomato. Of course, hand filling obviates such factors contributing to loss of quality as well as the very material one of loss of juice, but up goes the cost of packing!

The cans varying from half-full to overflowing of drained solids go to the juice filler. This is kept full of hot tomato juice and fills the can with juice even with the top. As explained above, this juice is from the drained fruit after peeling. It contains just as much food and condimental value as the more solid portion of the tomato and hence should be incorporated into the pack as an integral part of it. No machine has been invented which will fill a can to within a given distance from the top. If the tomato filler is working satisfactorily, from 5 to 10 per cent of juice is necessary to give the can a correct fill. If the filler gets out of adjustment due to a sudden change in the quality of the stock, or if the hopper is delivering too large a quantity of juice from the tomatoes crushed by the weight of those above, then the can comes through half-full of tomatoes. But the unthinking juice machine fills up the can with juice and we have another case of a watery looking pack. The top cannot be soldered on or crimped on to an absolutely full can. Provision is made by a dumper or other spilling device whereby this excess of juice is removed, leaving the level of the contents of the can approximately constant. Loss here may amount to as much as 15 per cent of the contents of the can.

The legitimate skin, core and seed waste amounts to about 5 per cent of the original tomato. The yield of goods in cans is 50 per cent, leaving a net loss of about 45 per cent. Almost all of this can be recovered and will amount to more than twice what the Government has commandeered to feed an army.

Manufacture of Concentrated Tomato Products

Wastes are not the only phases of tomato packing commanding the attention of engineers. Several other lines of tomato manufacture have been opened up involving engineering questions which are of moment not only to this industry but to

several others. This is the manufacture of the more or less concentrated products of pulped tomatoes used in soup and ketchup. Tomatoes are pulped in commercial practice by more or less disintegrating them either by crushing or a slight cooking, and passing them continuously into what is known as a "cyclone" machine (described later on) which separates the skin, seed and core from the juice and flesh of the tomato. A mixture of flesh and juice passes through together while seed, skin and cores are discarded as waste. This mixture of juice and disintegrated flesh is called cyclone juice and differs only from what is known as tomato pulp in the fact that it is not concentrated. This concentration of cyclone juice to the various pulps, sauces and pastes is an engineering problem pure and simple, and its successful operation can only be attained by applying engineering methods.

Concentration of tomato cyclone juice is effected by boiling out the water. It is this boiling that presents such problems to the industry. When one considers that the market value of the product depends on its thickness and color, he can realize that the factors determining quality militate against each other. Thus, to overcome this darkening by heat is the great problem. Since this is doubtless due to a chemical reaction, it possesses the factors of temperature and time. In other words, if we cook the juice quick enough or at a low enough temperature, good results may be effected. Vacuum evaporation secures the latter and gives a splendid product.

But this operation applied to tomato products does not present the simplicity of evaporation in vacuo of homogeneous liquors such as sugar syrups. Excessive foaming, caking in the heating surfaces of the pulpy fibrous mass, introducing the flavoring ingredients and handling the more or less pasty finished mass, all present problems which only recently have been satisfactorily handled by engineers.

Many tomato-pulping plants are not able to install the expensive equipment for vacuum evaporation or maintain the skilled service necessary for its control. To meet this demand engineers have endeavored to effect evaporation by several methods, all seeking to expose the rich and fibrous material to the action of air and temperature for as short a period as possible. Continuous evaporation, forced draft applied to ordinary steam-jacket kettles whereby dry air is continually removing the saturated air over the boiling mass, evaporating machines incorporating a rapid stirring of a small amount of juice exposed to a large heating surface for a brief interval, mechanical separation of fiber from the clear, colorless juice with high concentration of the latter, and then addition and mixing of the uncooked fiber to it, and boiling in wooden tanks with closed steam coils to insure absence of metallic contamination together with rapid boil, are all now being tried out.

Continuous evaporators seek to minimize labor but require careful control to secure a product of uniform consistency. I know of none on the market simple in construction and which operate more efficiently than an ordinary steam-jacket kettle.

Another large problem necessary to be solved is a method for storing and holding cheaply large quantities of tomatoes. As stated previously, the packer buys pretty closely up to his capacity, but the uncertainty accompanying transportation often results in a glut. This means either a driving of the factory to use up the goods or great loss from spoilage, usually both. In the Middle West some firms use a large tank of water into which the tomatoes are dumped. Others spray the piles of tomatoes in baskets or crates, while many merely stack them loosely to insure good ventilation. But to be a success the method developed must be considered in the light of the fact that the canned-tomato industry is widely distributed over the country, is composed of a large number of small plants, some near water and some not, and is not an industry operated by a very high class of labor.

Tomato Paste a Product That Cuts Waste Fifty Per Cent

That the tomato industry is a fertile field for the application of economies in operation is evidenced by the development of a tomato product which contains all the food and condimental value of the tomato, reduces loss from 50 per cent to 5 per cent and produces a product which can be sold for about one-half of the price of the regular canned tomato, figured on the basis of equal content of raw material. I refer to the tomato-paste industry.

In the manufacture of this product, tomatoes pass through large washing machines, then over sorting belts where the unsound material is picked out by hand, thence into a crusher and immediately into the previously mentioned cyclone machines. These consist of horizontal perforated metallic cylinders slightly open at each end, about two feet in diameter and three or four feet long, provided with a paddle rotating on the axis of the cylinder and barely escaping the sides. The violent beating of this paddle forces the juice and flesh of the tomato through the perforations while the seed, skin and cores, deprived of their juice, pass out through a small gate at one end of the cylinder. This dry material, comprising about 5 per cent of the original tomato, is called cyclone waste, and will be referred to again.

The juicy mass of liquor and ground tomato flesh from the cyclone perforations is called in the trade "cyclone juice," as distinguished from the more or less clear, watery looking liquid in the tomato which is familiar to all. This cyclone juice is then concentrated in the proportion of about 5 or 6 to 7, according to the character of the raw stock and the quality of the finished product. This industry, while a subsidiary of that of the whole tomato, has developed quite a respectable technology of its own in which is a splendid field for good engineering practice.

For instance, the market value of the finished pasty mass, called tomato paste, is proportional to the bright red color; the freshness of the tomato flavor, and the thickness, and, as stated previously, the ordinary concentrating methods of evaporation serve to destroy color and taste, while pastiness renders it difficult to handle in the kettles without burning or to transfer from the kettles to the fillers. To save color we are inclined to sacrifice pastiness (concentrate loss); to make it thicker and thus put more tomato in a can, there is a tendency to sacrifice color, taste and ease of operation.

Economies Now Obtained

Thanks to the prodding of necessity, these baneful effects have been minimized by adopting more efficient means of evaporation both at atmospheric pressure and in vacuo, while the handling of the pasty mass likewise has now reached a state of satisfactory development. Overcoming difficulties of concentration and handling, together with mechanical applications as substitutes for the hand labor of the ordinary peeling processes, is an eloquent example of the potentialities in engineering practice as it may be applied to food problems. This development cuts down the labor necessary to handle about 5000 baskets per day from somewhere near 140 persons to about 35, reduces the tomato waste from about 50 per cent to about 5 per cent, eliminates all waste to the consumer by giving him a product free from seeds and cores, saves tin plate by using a can containing 30 sq. in. in comparison with one containing 91 sq. in., reduces shipping cost from the fact that the standard paste can contains 6 oz. net weight while

the can of standard tomatoes of equal weight of tomato solids contains 32 oz. net weight, and at the same time materially lessens storage and conserves transportation space. This tomato-paste manufacture of course puts the goods in a form somewhat different from that with which the housewife is familiar, but a publicity campaign should demonstrate to the intelligent housewife that not only is she effecting a direct saving of 50 per cent of her bill for tomatoes, but also indirectly in that by this means she is enabling what is now waste to be utilized for other food purposes, directly as edible fat (oil) and cattle food (press cake).

But if we again apply economies in operation we find that even this 5 per cent of cyclone waste can be utilized. As stated above, it consists of the comparatively speaking dry cores, skins and seeds of the pulped tomatoes in the proportion of about two-thirds wet skins and cores, water, and one-third wet seed. These seeds contain a valuable edible oil which closely resembles olive oil, in fact, so much so that in Italy it has been largely used for the adulteration of olive oil. The press cake remaining after removal of the oil is valuable for stock feed. Inasmuch as the cake is ground up for this use, the skins can be ground in with it, thus insuring absolutely no loss, and rendering all of the tomato entering the plant a valuable commercial commodity.

The Industry in Need of Engineering Direction

Thus we see that simple as tomato packing seems to be, it is, notwithstanding, an industry in great need of development. It has grown to huge proportions in volume of business, but has not developed in the mechanical end at all commensurate. Thanks to the operation of the Food and Drugs Act, and the meritorious activities of the state inspection and control service, the industry has been raised from one of indifferent sanitation to a high state of excellence. But until men trained in engineering take hold of the problems awaiting solution, the industry will continue to blunder on and develop under the guidance of men whose whole engineering viewpoint is circumscribed by the narrow confines of their own establishments. Wastes await reclamation, factory procedure needs the application of approved engineering knowledge, and the time-worn practices of forty years need to be revised in the light of applied science.

TEMPERATURES AND THEIR DURATION DURING THE HEATING SEASON

By REGINALD PELHAM BOLTON, NEW YORK, N. Y.

THE unusual e treme of low temperatures which particularly affected the City of New York during the heating season of 1917-1918 invites careful study as to the effect of similar possible occurrences upon the installations of apparatus designed to effect the heating of buildings. The prevalence of extremely low temperatures in the vicinity of New York City is very limited as regards time, and the writer has pointed out on previous occasions that the existence of a temperature below zero has not usually prevailed beyond the early hours of the morning, but is followed by a sharply rising temperature about sunrise, and has rarely been at zero in the working hours of the day. In December 1917 and January 1918 such low temperatures were maintained, on some occasions, all day, with great inconvenience and suffering, due to the incapacity of heating apparatus to meet such a condition.

The length of time during which any given temperature below 70 deg. may prevail during a season affords an interesting comparative study, and a summary of the figures recorded by the Meteorological Observatory in the City of New York is presented in Figs. 1-3, in which the temperatures are inverted on the vertical scale, and the period of time is shown on the horizontal scale. Fig. 1 is the record of the season of 1904-1905; Fig. 2 that of 1913-1914; and Fig. 3 that of 1917-1918.

An examination of the mean temperatures recorded during the past 49 years shows that the average was 40.4 deg. This may be compared with the extreme low temperatures of the past heating season, the average of which was 37.66 deg. Compared by months, the average temperatures were as given in Table 1. It may be observed from this that at the end of the last season the average monthly temperatures were higher than usual.

Another interesting point which may be observed is that the temperature of 32 deg. and below was maintained in the past cold season about 35 per cent of the time of the season, which is very similar to that in Fig. 1, representing an average condition.

Reference to Fig. 2 shows that during about 50 per cent of the whole season the temperature ranged between 50 and 30 deg., and for about 25 per cent of the season the temperature was above 50 deg.; while in Fig. 3 the period during which

TABLE 1 COMPARISON OF AVERAGE TEMPERATURES (DEG. FAHR.) DURING THE HEATING SEASON

	Mean, 49 Years	Season of 1917 1918
October	55 6	52 6
November	44 1	41 4
December.	34 2	25 0
January	31 2	21 5
February	30 5	30 7
March..	37 5	41.6
April .	49 1	50 1

temperatures of 50 deg. and excess prevailed was not much more than 22 per cent.

It has generally been assumed that the lowest temperature for which provision must be made in heating the buildings of New York City is that of zero, and consequently the capacity of boilers or of heating apparatus is usually installed upon that basis. Reference to these diagrams indicates the extent to which the capacity of the heating apparatus or boilers is utilized, both as regards output and time, and the relatively insignificant period during which the lowest temperatures prevail. It is for this comparatively minute demand that a large part of the investment in boilers and heating systems is necessarily installed, and the relative expense of providing for this extra heating capacity seems disproportionate to the results achieved. Thus it will be seen that in the season of 1904-1905, which was one fairly representative of average conditions, the percentage of the season, when the temperature was 10 deg. or less, was only 0.8 per cent, yet it will be evident that at least one-seventh of the entire investment in boilers and heating apparatus

had been provided for use in this quite insignificant period of time.

In the season of the year 1913-1914 (Fig. 2), in which unusually low temperatures prevailed, and which was perhaps our coldest recorded season prior to last year, the period of

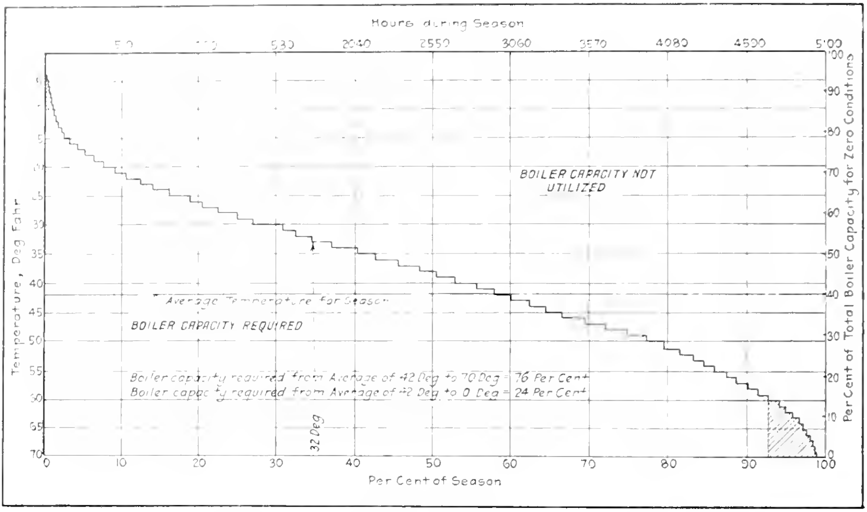

FIG. 1 TEMPERATURES AND PERIODS DURING HEATING SEASON OF 1904-1905, MANHATTAN

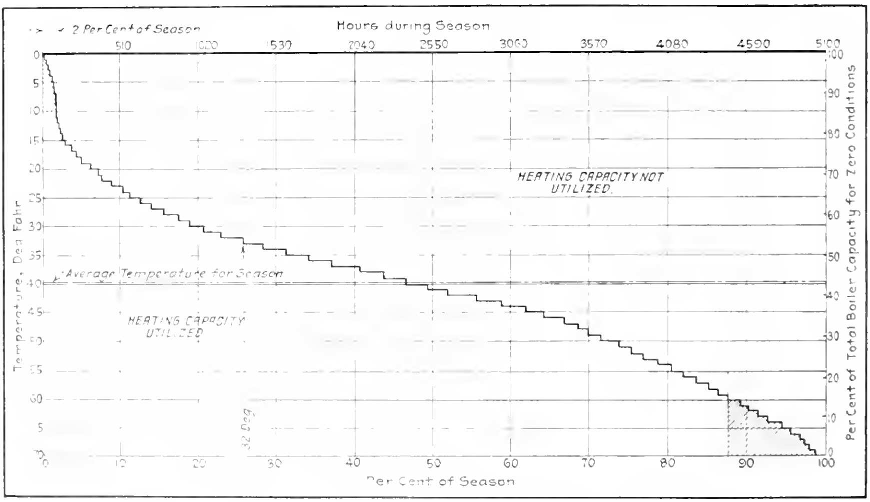

FIG. 2 TEMPERATURES AND PERIODS DURING HEATING SEASON OF 1913-1914, MANHATTAN

time during which the temperature of 10 deg. or less was in existence, was only 2.1 per cent of the heating season, as shown by the shaded space at the upper left-hand corner of the diagram.

During the past extremely cold winter (Fig. 3), when our temperatures descended as low as 12 deg. below zero, this proportion of the season during which the temperature was 10 deg. or less was only 1.8 per cent. It would thus seem that the use which is made of the extra capacity of our heating installation is not in excess of 5 per cent of the total period of the heating season. This leads to some consideration as to whether other means could not be found which would relieve the owners of property of the investment in a large amount of expensive apparatus so unprofitably utilized, and indicates a direction in which the ingenuity of the heating engineers of the country might very well be applied, to the advantage of all concerned.

It is possible that if some means for the substitution of gas or electricity as an auxiliary heating agent could be introduced at less expense for installation than the usual boilers, piping and radiators, it would be profitable to make use of those supplies of heat, even at prices greatly in excess of the actual cost of producing steam or hot water.

As a matter of fact, much fuel is wasted by overheating residences and apartments at times when the exterior temperature is above 60 deg. If auxiliary gas or electric appliances were

installed the use of steam might in some buildings be discontinued when the temperature rose above 60 deg., which even in the past cold season was the case during 295 hours, or about 6 per cent of the total.

The subject has acquired a certain aspect of necessity, since the past winter disclosed the fact that there may upon occasions occur temperatures falling substantially below zero, and prevailing for many hours at a time. For such conditions it may be said there are but few installations of heating apparatus in New York City proportioned to provide the necessary heating capacity. Boilers may indeed be forced to deliver additional output, but radiators and piping are not capable of relative increase to meet a condition such as that which prevailed during last winter on several occasions.

To add to heating apparatus for the purpose of meeting this contingency, so limited in period of time and yet so urgent in character, would involve enormous expense. The situation was met only to an inadequate extent last winter by the purchase and use of a multitude of oil heaters, electric heaters, gas radiators, and the wasteful burning of gas in flame burners, kitchen ranges and gas logs.

Looking at the other end of the scale of time and temperatures, as shown in these diagrams, we find another period of time during which such auxiliary apparatus might be utilized. It is that during which temperatures of 60 deg. and above prevail.

In the season of 1904-1905 such temperatures were in existence for upward of 400 hours, or 8 per cent of the season, during which time the capacity of an installation proportioned on heating at zero was utilized to an extent of less than 15 per cent. It would seem that during such a period economic use might be made of whatever auxiliary appliances and methods of supply of heat were provided to meet the excess conditions required during extremely low temperatures at the upper end of the diagram.

It is interesting also to note in this connection that during an average season, such as that of 1904-1905, the entire use which is made of the installed capacity of heating apparatus is only 24 per cent. up to the average temperature of 42 deg., while the capacity in use above that temperature to the limit of 70 deg. is 76 per cent. This again indicates the relatively expensive provision required to be made to maintain the temperature of our buildings during the prevalence of the lower temperatures of the season.

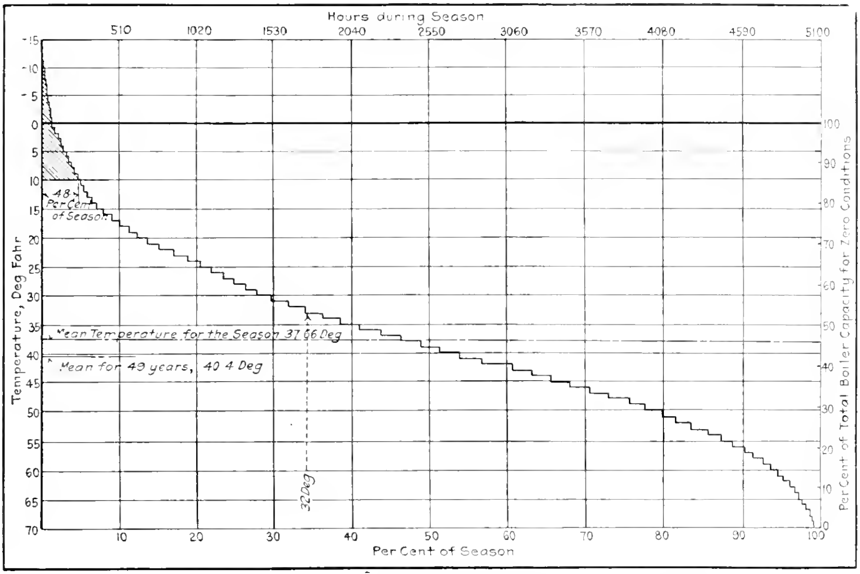

Fig. 3 Temperatures and Their Duration, Heating Season of 1917-1918, New York City

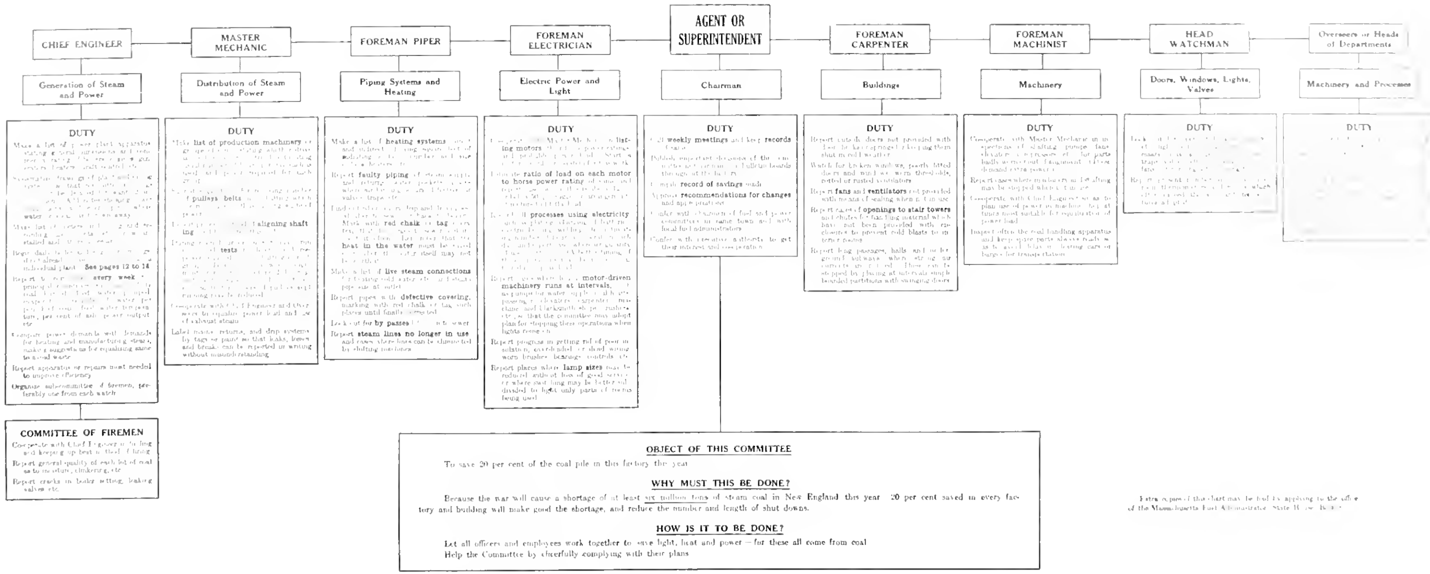
Owing to the enormous increase of Government war work, the governmental departments at Washington are being flooded with letters of inquiry on every conceivable subject concerning the war, and it has been found a physical impossibility for the clerks, though they number an army in themselves now, to give many of these letters proper attention and reply. There is published daily at Washington, under authority and by direction of the President, a Government newspaper—*the Official U. S. Bulletin*. This newspaper prints every day all the more important rulings, decisions, proclamations, orders, etc., as they are promulgated by the several departments and the many special committees and agencies now in operation at the National Capital. This official journal is posted daily in every post office in the United States, more than 56,000 in number, and may also be found on file at all libraries, boards of trade and chambers of commerce, the offices of mayors, governors and other state and federal officials. By consulting these files most questions will be found readily answered; there will be little necessity for letter writing; the unnecessary congestion of the mails will be appreciably relieved; the railroads will be called upon to use fewer correspondence sacks and the mass of business that is piling up in the Government departments will be eased considerably. Hundreds of clerks, now answering correspondence, will be enabled to give their time to essentially important work, and a fundamentally patriotic service will have been performed by the public.

FACTORY FUEL AND POWER COMMITTEE — ORGANIZATION CHART



Bulletin of Advisory Engineering Committee of Massachusetts Fuel Administration

The Society's membership is taking an active part in the various states in the conservation of fuel. In Massachusetts, the Advisory Engineering Committee, appointed by James J. Storrow, Massachusetts Fuel Administrator, consists of seven members, of whom six are members of this Society, as follows: Ira N. Hollis, *Chairman*, 11 Boynton Street, Worcester; Charles T. Main, 201 Devonshire St., Boston; William G. Starkweather, 53 State Street, Boston; George P. Gilmore, 46 Dudley Street, Fall River; Arthur T. Safford, 66 Broadway, Lowell; Joseph A. Skinner, Holyoke, and Thomas Hawley (non-member), 115 Huntington Avenue, Boston.

This committee has just issued a report specifically for use in Massachusetts, but which, as expressed by one fuel engineer, "would be an admirable report for the whole 'United States,' if these two words were substituted on the cover for the word 'Massachusetts.'" The report is known as Bulletin No. 1 and deals concisely with the following subjects:

1 Necessity for reduction of demand for coal by all users.

2 Methods for saving coal, including a discussion of general principles and the special conditions to be met in mills, factories, shops and power stations, including consideration both of central stations and purchased power. Detailed suggestions are further given for the boiler room, the engine room, manufacturing processes, heating of shops and work rooms, the lighting system and the power-transmission system.

3 Methods for saving coal in business and apartment buildings, hotels, schools, churches and public buildings.

4 Methods of saving coal in residences and smaller public buildings.

The bulletin concludes with forms for daily boiler-room and engine-room records and power-station reports. Its distinctive feature is the information given regarding the Massachusetts plan, which has been successfully tried out and is now recommended for universal adoption for the organization in each plant of a Fuel and Power Committee composed of employees of the company, whose duty it is to see that fuel is burned economically, and of even more importance, to prevent the waste of steam and power after the heat or power have been generated. This affords a means for coöperation, and it is felt to be imperative that all district fuel committees should see that the industries coming within their reach are so organized. In fact, it has been proposed that the delivery of coal should be conditional upon such organization.

In order to clearly outline the functions and scope of such a Fuel and Power Committee, the report publishes an organization chart which is reproduced herewith for the benefit of other communities, as well as those in Massachusetts. The chart is so clearly arranged that no further explanation is necessary.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Second Law of Thermodynamics

TO THE EDITOR:

Mr. Okey's letter published on page 467 of the June number of THE JOURNAL brings another instance of the periodic outcropping of misunderstanding of the "Second Law of Thermodynamics." This misunderstanding may be as much the fault of the teachers of thermodynamics as of the pupils, but in either case the widespread confusion of mind is deplorable.

First, as to Mr. Okey's "operative" apparatus, this constitutes no infraction of the Second Law. It develops its power quite normally from the heat flowing from the warmer body (the air surrounding the boiler) to the colder one (the air chilled by atmospheric evaporation) quite as any heat engine develops power from fuel heat flowing to refrigerator. Air is everywhere being chilled by atmospheric evaporation; but it has to be warmed first by sun heat before it can do it. If Mr. Okey's turbine had not been interposed, the atmospheric evaporation would have chilled the air surrounding his boiler just the same.

This is exactly as all the sun heat reaching this earth eventually must re-radiate into space. If the process be temporarily interrupted by the storage of the heat in coal beds, with the incidental driving of human engines before it is allowed to escape to refrigeration, it is not altered thereby. The Second Law holds at every point.

The trouble in Mr. Okey's case does not lie in his apparatus, but in his explanation of it. His confusion of mind arises from the fact that he has been told that heat is convertible into work, and that our prime movers are "heat engines." They are not. There is no such thing, in careful phrase. They are all "temperature engines." The basic laws explaining these statements follow.

Every form of energy is partially convertible into every other form of energy, with conservation of quantities. This is, in reality, the proper statement of the "First Law" of thermodynamics. The transformation of heat into work is merely one instance of this general law, which runs through all fields of energetics.

No form of energy is wholly convertible into any other form. This is a basic law of energetics as important as either the so-called "First" or "Second" laws. Yet, so far as the writer is aware, it nowhere finds expression in the textbooks of thermodynamics. It should be called the Second Law, and what is now called the Second be made the Third.

Each form of energy is convertible into any other *only to the degree that range in its intensity factor (in the case of heat—temperature) exists in the environment.* This is, in reality, the general statement of the so-called "Second Law," preferably to be called the Third, in a form applying directly to problems in energy transformation. Of this law the limitation to "heat engines"—and the thing which proves that they should be called "temperature engines" is the basic formula: $(T_1 - T_2)/T_1$—is merely a single instance. We have not yet acquired any foundation for computing efficiencies nor for comprehending actions until we have the significance of this cosmic law well in mind.

None of these laws constitutes any denial of the possibility of deriving work from the heat of the atmosphere. The earth's atmosphere, particularly near the earth's surface, is relatively a quite warm thing, heated by sun heat. Wherever may be found a spot colder than the local atmosphere—in the sea, on the mountain tops, in the upper atmosphere, etc.—there many a means for the development of power by the connection and interaction of the two places may be devised. Not one of these devices would give any surprise to the thermodynamicist, because none would infringe the basic laws against thermodynamic perpetual motion.

This frequent evidence of confusion of mind regarding the fundamental principles underlying the transformation of energy—one of the most widespread fields of applied science—is ground for deep regret that not even a single technical school boasts a chair in *Energetics*, teaching pure mechanics, thermodynamics, electrical and chemical energetics simultaneously, as one subject.

SIDNEY A. REEVE.

New York, N. Y.

TO THE EDITOR:

I have been greatly interested in Mr. Okey's very ingenious little fallacy regarding the second law of thermodynamics in the June number of THE JOURNAL.

It is possible that you already have had many much better explanations of the situation than I can offer.

In the first place, I would like to compliment Mr. Okey on the entire arrangement. It is not often in these days that any new thermodynamic system is originated. Mr. Okey has set forth what seems to me to be quite a novelty, and has carried it out in a very ingenious way. I hope to be able to inspect the original apparatus before a great while.

The only point to which I take exception is the statement that the second law of thermodynamics is violated. This is not the case.

In order to completely understand the matter, we must include with the apparatus such part of the atmospheric action as will make a complete closed cycle.

This is that portion of the room which will take away the water vapor from the SO_2 condenser and return condensed water. We can do this without destroying Mr. Okey's principles in the least. Suppose that there is a closed chamber surrounding the SO_2 condenser as shown in Fig. 1, in which the parts which are added are shown in dotted lines. This chamber takes the water vapor which is evaporated, and by extracting heat from it, by contact with the coldest of the surrounding bodies, condenses the water, which is then returned to be re-evaporated.

There will be a certain constant pressure in the added chamber. The saturation temperature corresponding to this will be the temperature at which heat is taken away in the cycle, and will be the lower temperature of the second law of thermo-

dynamics. The upper temperature — of course the temperature at which heat is added in the SO boiler.

I think it will be found that the completed apparatus is

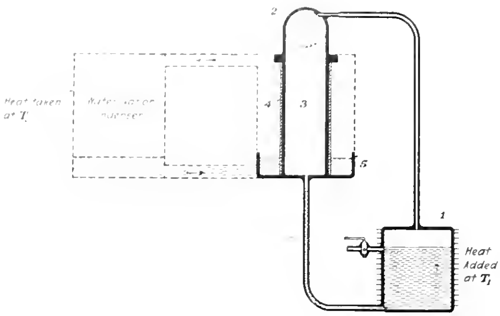


FIG. 1 MODIFIED FORM OF OKEY APPARATUS FOR OBTAINING MECHANICAL WORK FROM THE HEAT IN THE AIR

entirely consistent with the second law. It forms, in fact, a binary-vapor cycle, exactly identical with some such cycles which have already been fully worked out.

S. A. MOSS.

West Lynn, Mass.

Committee on Development Proposed

TO THE EDITOR:

Referring to the A.S.C.E. resolutions creating a Committee on Development [see p. 712—EDITOR], I cannot help but feel that a most important and timely step has been taken by the Civil Engineers. The social, industrial and economic changes to which the preamble properly calls attention have been the result of a development with which the engineer has been more closely associated than any other profession or group. Therefore they demand our earnest and constant study, and in the opinion of many they necessitate a readjustment and a restatement of the aims of our various engineering societies.

Another problem requiring an early solution is the organization of all engineering societies, national and local, in such a manner as to harmonize and coördinate their efforts toward promoting the interests of the engineering profession and serving the community. It may be said—I believe without danger of contradiction—that the principal aims of all the engineering societies, according to the conception of their membership, are more or less identical (although expressed in various ways), and that the points of difference relate to professional and geographical limitations. Organization must therefore look toward joint action where the aims are general and identical and toward separate action where aims are specific and individual. In view of the magnitude of such an organization, however, and in view of the difference in structure and in scope of the many units to be coördinated, a plan for coöperation must be preceded by thorough discussion and clear statement of the present-day aims of the units to be combined.

These considerations make me feel that our Society should take up at the earliest possible time a broad and thorough examination of its aims, and that such examination would best be coincident with similar action in other national, and preferably also local, engineering societies. Previous attempts and discussions in our Society have not carried us very far, largely, I believe, because they have not been sufficiently general. May I suggest, therefore, that a committee of our Society similar to that of the A. S. C. E. might be of incalculable benefit just at this time, and that pressure upon other national societies, also to follow the lead of the A. S. C. E., would be appropriate. If constituted along the lines indicated in the resolutions referred to, i. e., composed mostly of section representatives, such committees of national societies could not help but spread the interest and discussion of this vital subject to every city, town and hamlet of the country where engineers are found.

If a committee as suggested were soon appointed, a report could no doubt be submitted to the Council previous to the Annual Meeting in December, so that a general discussion on the part of the whole Society could then take place.

LOUIS C. MARBURG.

Philadelphia, Pa.

Economic Effects of Impurities in Coal

TO THE EDITOR:

In discussing the subject of low-grade fuels and impurities in coal at the Spring meeting, Mr. Pigott made the statement that the principal effect of burning a lower-grade coal in the boiler furnace was the reduction in boiler capacity. With coals from the Middle West there is a considerable decrease in efficiency as well, as with coals containing a high percentage of ash there is inevitably a greater ashpit loss than with better coals, and it should be borne in mind that while the average fireman can burn good coal economically with the proper equipment, it takes an exceptionally good man to burn poor coal so as to get the most out of it. In this connection the cost of handling the excess ash and moisture in the coal should be considered as well as the disposition of the increased amount of refuse from the furnace; further, with poor grades of coal increased capacity can be obtained only with increased ashpit loss, and under ordinary conditions and variations of coal it is extremely difficult to determine the most economical point of operating.

In order to obtain the required capacity for peaks some of the companies who have experienced considerable difficulty in obtaining good coal have made it a practice to purchase only enough good coal to carry them over the peaks, as it is possible to get along during off-peak periods with the lower grades of fuel, which are cheaper and more easily obtainable. This good coal is segregated so that it can be distributed to the boilers by hand or by special equipment during the peak periods, after which the boiler rooms return to their regular operation as soon as possible with the coal ordinarily received.

ALEX D. BAILEY.

Chicago, Ill.

"The Wonder Ship of the World" was launched at the Bethlehem Shipbuilding Corporation, Union Plant, Alameda, when the *Defiance*, a 12,000-tonner, slid off the ways just 38 calendar days from the laying of the keel.

Director-General Schwab called the *Defiance* the "Wonder Ship." Mr. Schwab declared that the building of this boat in 38 days, including Sundays and holidays, really is the most remarkable performance in shipbuilding history. On a basis of tons of steel fabricated into the vessel daily, the building of the *Defiance* was about 30 per cent better than the *Tuckahoe*, the 27-day ship built by the New York Shipbuilding Corporation. This comparison is not absolutely accurate, but it is considered fair. (*Emergency Fleet News*, vol. 1, no. 19, July 11, 1918, p. 16)

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

PRESIDENT MAIN said that "it was number 7" when the latest member of his personal staff left for War Work. This, in addition to his personal devotion to the service of the Government to the exclusion almost of his own business, will explain, if explanations are necessary, the earnestness with which the President has just appealed by letter to the membership for the services of every competent engineer in the country in the interest of the Government.

It is here that announcement should be made of the summons of the Committee on Emergency War Training to Mr. Ernest H. Hartford of the Society's Staff, to go to Washington and assist in the important work of organizing the Emergency War Training of technical men, throughout the United States. Forty thousand men are now being given an emergency training in the various schools and colleges and by the end of the year it is hoped to bring this number to one hundred thousand.

There is one feature relating to the appeal for enrollment of engineers for war service which requires explanation, namely: that while we are continuously furnishing names of men in response to specified requests by the different Bureaus of the Government, and the industries generally, only in rare cases are we able to reverse the operation and place a man anxious to serve. We have first to await the request, and the patience of such members is requested in this respect.

There is unfortunately small prospect, so far as we are able to judge, that the war will come to a speedy close, and in consequence thousands and even millions of men will probably be required. There is small doubt but that ample opportunity will eventually come to every one to contribute his services.

An interesting event in engineering circles which has come to our notice is the inauguration of the Engineering Institute of Canada, of which our esteemed member, Mr. H. H. Vaughan, is president. The intention of the Institute is to broaden the field of usefulness formerly covered by the Canadian Society of Civil Engineers, by uniting "all the Engineers in Canada, to whatever branch of the profession they may belong, into one Society."

We are just in receipt of the first number of their Journal, and it is of interest to know that it is uniform in size with our own JOURNAL, that is, nine inches by twelve. If any one doubted the wisdom of adopting this size, it would be well to observe that the nine-by-twelve size, which was determined upon by our Society a number of years ago, is used by a large proportion of the 1200 periodicals received in our Library from all portions of the world.

It will be the desire of this Society to coöperate with the Engineering Institute of Canada in all possible ways, and it may be that we can do this best by interchanging matter for the Engineering Survey and reviews of technical literature which we have developed; this is uniform with the practice of giving Engineering Survey material to the Research Information Committee of the National Research Council.

There is still further opportunity to coöperate in the matter of standards, President Vaughan having been appointed the Canadian representative on the British Engineering Standards Committee.

A noticeable feature of the policy of the Engineering Institute seems to be the emphasis placed upon sections and branches and the benefits to be obtained by participation of the Institute and also of each branch in matters of legislation. A conspicuous division of the Institute's committees comprises the legislative committees and there is besides a strong committee in each of the branches of the Institute throughout the Dominion. This is in keeping with the announcement of the object of the Institute, which is—

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

CALVIN W. RICE,
Secretary.

War Industries Readjustment Committee

THE National War Industries Readjustment Committee of the Society has been hard at work and has received numerous requests from manufacturers desiring to handle war orders. Government bureaus have been assisted in placing such orders. The Committee is anxious to learn of manufacturers who have an excess of work or whose production is lagging and would like to sublet part of their work.

For various reasons the output of war material is far below what it should be. Some of the main reasons are congested transportation, lack of material and lack of coördination. The purpose of our Committee is to do what it can to overcome such difficulties. To this end the Chairman, Mr. Parsons, has just returned from Washington, where he has been in conference with Messrs. George N. Peek and Charles A. Otis, of the War Industries Board. Mr. Otis is Chief of the Resources and Conversion Section, and has worked out a splendid regional plan with regional advisers as follows:

Bridgeport, B. D. Pierce, Jr., care Chamber of Commerce
New York, William Fellowes Morgan.
Philadelphia, Ernest T. Trigg, 322 Race St.
Pittsburgh, George S. Oliver, care Chamber of Commerce
Rochester, Esten A. Fletcher, care Chamber of Commerce
Cleveland, W. B. McAllister, care Chamber of Commerce
Detroit, Allan A. Templeton, Detroit Board of Commerce
Chicago, D. E. Felt, 29 So. LaSalle St.
Cincinnati, Edwin C. Gibbs, 31 East Fourth St.
Birmingham, T. H. Aldrich, 322 Brown-Marx Bldg.
Kansas City, F. D. Crabbs, care Chamber of Commerce
St. Louis, Jackson Johnson, care Chamber of Commerce
St. Paul, D. R. Cotton, care Chamber of Commerce
Milwaukee, August H. Vogel, Pfister & Vogel Leather Co.
Dallas, Louis Lipsitz, 407 Southland Life Bldg.
San Francisco, Frederick J. Koster, care Chamber of Commerce

Atlanta, Baltimore, Boston and Seattle appointments will be made very shortly.

The idea is that through this means it will be possible to place Government requirements in communities or regions, and expedite production through the cooperation of the various organizations and facilities within those regions. In order that our Society may do its utmost, it has been decided to cooperate in each of these regions. To this end President Main has appointed the following representatives to work with the above regional representatives of the War Industries Board in their several localities:

Bridgeport, Conn., Harry E. Harris, P. O. Box 852
New York City, G. K. Parsons, 29 Pine Street
Philadelphia, Pa., C. N. Lauer, care Day & Zimmerman
Pittsburgh, Pa., J. M. Graves, 435 Sixth Ave.
Rochester, N. Y., Ivar Lundgaard, 208 Culver Road
Cleveland, Ohio, F. H. Vose, 3203 Whitethorne Road, Euclid Heights
Detroit, Mich., G. W. Bissell, Mich. Agri. College, East Lansing, Mich.
Chicago, Ill., A. D. Bailey, 21 Elmwood Ave., La Grange, Ill.
Cincinnati, Ohio, Fred A. Geier, 2301 Grandview Ave., E.W.H.
Baltimore, Md., W. W. Varney, 710 North Carey St.
Atlanta, Ga., Robert Gregg, 960 Ponce de Leon
Birmingham, Ala., W. P. Caine, Ensley, Ala.
Kansas City, Mo., J. L. Harrington, Rockhill Manor
St. Louis, Mo., R. L. Radcliffe, 701 Laclede Gas Bldg.
Milwaukee, Wis., W. M. White, 747 Summit Ave.
Dallas, Tex., A. C. Scott, Scott Engineering Co.
San Francisco, Cal., B. F. Raber, 2027 Delaware St., Berkeley, Cal.
Seattle, Wash., R. M. Dyer, Puget Sound Bridge & Dredging Co.
Boston, Mass., A. C. Ashton, 33 Columbus Ave., Somerville, Mass.
St. Paul, Minn., Oliver Crosby.

It is the desire of the War Industries Board that our members act in an advisory capacity in the several regions. The reason for this is that our members being largely connected with industry are in the best position to advise regarding the feasibility of manufacturing, the interpretation of specifications, the adaptation of machines and processes, and the facilitation of production. In each of the regions there will be subcenters, and it will probably devolve upon our Society to be represented in each of these centers. It is likely that committees will be formed for specific technical and semi-technical questions, and our advice will be valuable in these committees. Further, it behooves us to be ready to fit in to the organization as it is developed by the War Industries Board.

The relation of our national War Industries Readjustment Committee to the several regional representatives of our Society will be that of the clearing house, supplying information and describing the methods which others are using, thus keeping our members informed of the best that is being done in other regions.

This Committee will be glad to answer inquiries and help in every way that it can to coördinate the activities of our representatives and the War Industries Board. The present headquarters of the Committee is in care of the Chairman, G. K. Parsons, President of the G. K. Parsons Corporation, 29 Pine Street, New York City.

Dr. Garfield to the Society

A letter of commendation has been received by President Main from Dr. Harry A. Garfield, U. S. Fuel Administrator, on the work accomplished by the Fuel Conservation Committee in preparing the Fuel Symposium for the Worcester Meeting of the Society, and for its use by the Publication Committee in The Journal. The letter is given below:

Washington, D. C.,
June 25, 1918.

The American Society of Mechanical Engineers.
Mr. Charles T. Main, President.

Dear Mr. Main:

Your Society is to be congratulated on its efforts for fuel conservation as set forth in this fuel-economy symposium. True Americanism calls for the most careful and efficient use of fuel—the driving force of war and industry.

Coal production, hand in hand with railroad service, has been increasing tremendously during recent weeks; but regardless of the supreme efforts being exerted, some parts of the country and some industries will have less coal than they want during the coming winter.

The demands of our great war machine are increasing hour by hour and they must be met. War requirements call for more coal, more raw materials of all kinds. Our transportation lines are clogged with the moving of the coal, of all the other raw materials and of the finished products.

Communities that have heeded the nation-wide warning to order early will be in far better position than those that have failed to heed the warning. War industries will be supplied. Other industries will receive coal and oil in proportion to their importance and the measure of their supply will depend on how faithfully everybody practices conservation.

Yours very truly,
(Signed) H. A. Garfield,
United States Fuel Administrator.

French Books Sent from the War Zone

The following is a letter which the Secretary has recently received from one of our members at the front, which gives an interesting personal note. The writer is a Canadian and was employed before enlisting in the capacity of assistant works manager in the Canada Machinery Corporation, Ltd., Galt, Ont. He is now in the 3d Brigade of the Canadian Field Artillery.

The books referred to have been received and placed in the library of the Society. Their titles are L'Essai des Combustibles, a translation of Fischer's Manual, and Résistance de Matériaux, by Ch. de Mussan.

Dear Mr. Rice:

Some time ago I sent you a couple of French textbooks which I picked up in the ruins of an engineering school. This school was evidently conducted by a mining association as an educational institution for the sons of miners. From scraps of drawings which were lying about, it must also have served as an engineering office for quite a large section of the mining area. At the time I found the books our brigade was in action in the town quite close to the place, and when things were quiet I used to dig around the building to break the monotony. One trip there I shall not forget, because Fritz opened up on the building while I was there and I am not a lover of flying bricks or steel. The place stands on a hill and as it is only a little over two miles from the enemy trenches, it is often used as a calibration point for his artillery.

I hope the books are of interest and some day I hope to be able to send you the pieces which I cut from the front pages showing the name of the town and school.

I wish there were time to write even a short synopsis of the work of the Canadian Field Artillery as I have seen it since January 1917. It is a most interesting branch of the service and especially during periods of open warfare. Sometimes the shelling around our positions is terrific and at other times there are quite long periods of comparative inactivity on the part of Fritz. But whether Fritz is active or not, the harrassing fire by our little guns goes on day and night, the intensity depending on the importance of the front. It is our policy to fire on every German who can be reached, and our 18-pounders can reach considerably farther than is generally known.

No doubt the enemy intends to make a big drive again very

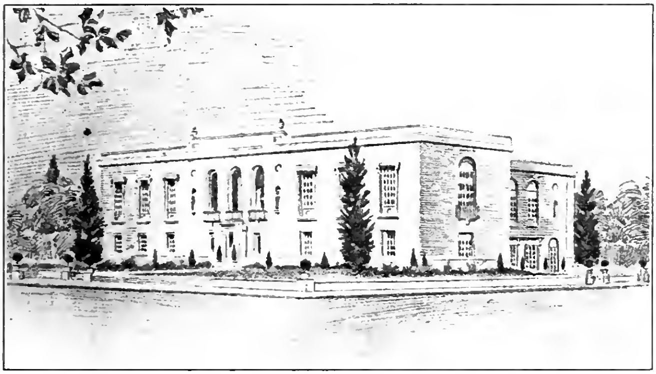
soon. It is like living on a volcano, but we all feel extremely confident that the showing to be made by the Allies will far surpass those in the past. Every one is working hard and as far as I can judge the stage is set for the greatest battle in history. We are all grateful to Uncle Sam for the real response he is making to our call for assistance. The American soldiers I have seen here are just the type we Britishers are proud to have as fighting partners, and with such men as you are sending over, together with the wonderful French and Italian soldiers, there can be only one result, a clean win for our side.

Bdr. P. G. Welford.

The Dayton Engineers' Club and Its New Building

An ideal home, yes, and more than that, a home of ideals.

This characterizes the Engineers' Club of Dayton in its new home, which it was the pleasure of the Secretary to visit a short time ago during a trip through the West and South. Our Society, in company with others, had been cordially invited to the original organization meeting of the Dayton Engineers' Club several years ago; and similarly to the dedication of its beautiful new clubhouse last February, which, however, the Secretary was unfortunately unable to attend. Suffice to say that whereas there may be engineers' club buildings which have cost more, as in the case of the Engineers' Club in New York, nevertheless, there is no more beautiful and well-appointed engineers' clubhouse in the world than the one which can now be found in the city of Dayton.



New Home of the Engineers' Club of Dayton

The original conception recognized that a meeting place permitting the fearless and thorough discussion of engineering problems, coupled with the fostering of good fellowship, was quite worth while and would confer lasting benefits upon the community. The splendid building came as a result of the generous desire of two of Dayton's public-spirited engineers, both of whom, incidentally, are members of our Society. The building is located on a choice lot facing the river, with adequate grounds to give it a setting, and is substantially constructed with a view to permanence and utility. The entrance to the main floor is generous and attractive. On the right is a common room, with piano, comfortable divans and pool tables. In the center are the main stairs up. To the left are the lavatories and rooms for checking wraps. Two or three steps down and in the center are the main rest rooms, with possibilities for dining *al fresco*. Upstairs is the main auditorium, with a large lounge on the right and library on the left.

Notwithstanding the excellence of the architecture and setting of the building, which, obviously, are so favorable, the impressive feature of all is that the Dayton Engineers' Club is dedicated to:

The dissemination of the Truth.
The promotion of useful education and civic righteousness.
The fostering of good-fellowship among our Miami Valley Engineers.
The professional advancement of our members.
The inspiration and encouragement of the younger men.
The making of a technical City, where creative endeavor finds reward.

Nothing could so hearten the work of the engineer, and particularly of the young engineer, as to see this evidence of idealism and devotion to the higher things of life in relation to his daily work.

History of the Providence Engineering Society

In the Providence Magazine for May 1918, published by the Providence Chamber of Commerce, there appears a history of the Providence Engineering Society, written by Luther D. Burlingame, Mem.Am.Soc.M.E., from which the account given below is taken. This society bears the distinction of having been originated, and until within a few years conducted, in the interests of those in the mechanical engineering profession. For several years past it has been affiliated with the American Society of Mechanical Engineers.

As far back as 1789 the Providence Association of Mechanics and Manufacturers was organized for the purpose of "promoting industry and giving a just encouragement to ingenuity, that our manufactures may be improved." This association had on its rolls the names of many distinguished men. The meetings were held in the Old State House, where an important library was collected, which became in 1877-1878 the nucleus of the present Providence Public Library.

Following the dissolution of this old organization, a group of men interested in mechanics and mechanical engineering, came together in 1894 to form an organization devoted to the interests of those mechanics branches. A constitution was adopted and the society started on its work with twenty-seven charter members. Arthur A. Fuller, now with Stone & Webster Co., Washington, was the first president. The name Rhode Island Association of Mechanicians was first adopted but as it did not seem to fit the ambitions of the leaders of the new organization, the name was soon changed to the Providence Association of Mechanical Engineers, under which title its activities were carried on for more than twenty years.

The first regular technical meeting was held on March 12, 1895, and was a lecture on electricity by Marion C. Happoldt, one of the charter members. During the first year practically all of the lectures and papers were by members and local engineers. In the early years a group of men from the Brown & Sharpe Manufacturing Co. were especially active in the organization and Luther D. Burlingame was the second president.

In 1911 the Association broadened its field of activities by becoming affiliated with The American Society of Mechanical Engineers, and joint annual dinners with the officials of that

Society, the first of which was held May 3, 1911, became important and regular events. In November 1915, at a joint meeting and dinner, with several hundred members of the Boston Engineering Society as guests, plans were consummated for the merging of the old Providence Association of Mechanical Engineers into the present Providence Engineering Society. The purpose of the reorganization was to bring together all classes of engineers in a single organization, modern requirements being such that all the various branches of engineering are found to have much in common, even though there may be wide variation in the technical requirements of each branch. The spirit of coöperation was shown at a recent meeting when there were present as speakers the presidents of the mechanical, civil and electrical national engineering societies.

In order that the specific interests of each group of engineers may be properly cared for in the larger organization, sections have been organized, representing each of the engineering interests most prominent in Rhode Island. These comprise sections on efficiency, municipal engineering, structural work, designing and drafting, power, machine shop, and chemistry. In addition there is a student section, making it possible for student engineers to be identified with engineering activities, with which they may later find themselves connected in a professional way.

An important program has been arranged for next season. During the past year there have been held eleven regular meetings of the society and fifty section meetings. Addresses on matters of current interest have been presented by engineers of national prominence at the regular meetings while the section meetings have been devoted especially to matters of engineering connected with the war.

The society has in operation an employment bureau for the reciprocal benefit of its members. It also publishes a monthly bulletin containing the program for future meetings and other items of interest to the members. Quite recently the society carried out a complete classification of the engineers throughout the state showing their availability for military or auxiliary civilian service. In addition to this work the society made several suggestions, which were later adopted, with reference to the proper guarding of public utilities and the securing of emergency fire-fighting apparatus. During the past year there has been an increasing number of the society members in the Service, and the service flag now contains thirty-five stars.

The present president of the society is Robert W. Adams and it is due largely to his energy and interest that the society is steadily progressing, the membership now being approximately 500. The society has attractive headquarters in the Dr. Carr building, 29 Waterman Street.

Edgar Marburg

Edgar Marburg, professor of civil engineering in the University of Pennsylvania and secretary-treasurer of the American Society for Testing Materials, died suddenly in Philadelphia on June 27.

Professor Marburg was graduated from Rensselaer Polytechnic Institute in 1885 with the degree of civil engineer and served successively in the engineering departments of the Keystone Bridge Co., the Phoenix Bridge Co., the Edge Moor Iron Co. and the Carnegie Steel Co. In 1892 he was named for and accepted the position of the head of the civil-engineering department in the University of Pennsylvania.

In 1898 Professor Marburg was one of the group to organize in Philadelphia the American Section of the International Association for Testing Materials and early in 1902 he was elected secretary of the section. Within a few months he had written to the executive committee such a clear statement of the purposes which an American testing society should fulfill that the committee decided to recommend the termination of the existence of the section as such and the establishment of a new society, which would hold membership as a body in the international association and, while affiliated and forming the American branch, be free to set forth its aims independently and adopt its own mode of procedure. The plan for the new society was drawn up on the lines laid down by him—which are those followed today—and the new body formally launched as the American Society for Testing Materials in June 1902 with Dr. Charles B. Dudley as president and himself as secretary-treasurer.

What the success of the society has been is not necessary to recount in detail. It is sufficient to say that the membership is now 2261, the annual receipts $39,687, while the standards it has adopted number 107. So excellent has been the work accomplished that the Government has in the last two years translated certain of the specifications into foreign languages, thus making the society work a helpmeet in the extension of American foreign trade.

While the profession knows him chiefly for his work in the society, Professor Marburg was no less successful as a teacher. In conjunction with his colleague in mechanical engineering, the late Prof. Henry W. Spangler, he deserves credit for having planned the excellent engineering laboratories of the university. The most important of his writings was his book on Framed Structures and Girders, published in 1911. For years he was a contributor of editorials to the *Engineering Record*.

Professor Marburg was a member of the American Society of Civil Engineers, past-president of the Engineers' Club of Philadelphia, past-secretary of the Society for the Promotion of Engineering Education and past-chairman of the committee on science and arts of The Franklin Institute. He was honored with the degree of doctor of science by the University and of doctor of laws by Franklin and Marshall College.

Dr. James Douglas

Dr. James Douglas, honorary member of the American Institute of Mining Engineers, died June 25, 1918, at the age of 81, in his home in New York. He was a scholarly man of the highest professional attainments. Besides being rated one of the foremost metal and mining authorities in the world, he had a deep interest and sympathies in the field of philanthropy.

To the engineering profession he contributed not only from his knowledge but also from his possessions. In 1915 he made an initial gift of $5000 to the Engineering Societies Library for an endowment fund, to which he added $95,000 in 1916, making his total donation $100,000. By the provisions of his will a bequest of another $100,000 has been made to the American Institute of Mining Engineers for library purposes.

A brief review of his life shows an unusually versatile and brilliant mind, which led him to make important contributions to an extraordinary variety of professions.

Dr. Douglas was born in Quebec, Canada, in 1837 and educated at the University of Edinburgh where he began his study of medicine, and at Queen's University, Kingston, Ontario. He traveled extensively in Europe and the Orient, visited Egypt several times, and brought back from his travels important archaeological collections which he later donated to the Metropolitan Museum of Art.

After the period of travel he returned to Edinburgh and continued his studies in medicine and surgery, and subsequently entered the ministry with the idea of combining the

two professions. In the full swing of his studies in medicine, theology and literature, however, his plans were suddenly changed. His father had invested heavily in gold and copper mines in Canada and seemed in danger of losing his entire fortune because there was no economical process of extracting the two per cent copper ore the mines contained. Dr. Douglas had been much interested in chemistry and the jeopardy of his father's finances led him to take up the subject practically in connection with mining. He returned to Canada again where, in collaboration with his friend, the late Dr. Hunt, he worked out the well-known Hunt & Douglas process for the extraction of copper.

Dr. Douglas came to this country in 1875 and became connected with several copper companies in applying his theory of extraction, finally entering into business relations with the firm of Phelps, Dodge & Co., of which he later became president and chairman of the board of directors. It has been said that Dr. Douglas supplied the imagination which, added to the money and careful business management of the members of the firm, raised this company to its very high place among mining industries.

It was on his suggestion that the first traction engines used in the Southwest were employed in hauling coal from Bisbee to the railroads. He built the railroad from Bisbee to Fairbanks to further facilitate the handling of the ore, and otherwise developed facilities for conducting mining operations on a large scale for the delivery of the coal.

Dr. Douglas' liberality and broadmindedness made him the friend of the engineering profession. His mines and smelting plants were always open to other engineers, with whom he believed an exchange of ideas mutually beneficial. In this connection H. W. Hardinge tells that a chance remark of Dr. Douglas' resulted in changing the whole method of copper smelting in Colorado. The remark led Mr. Hardinge to convert his lead stack into a composite lead and copper furnace, a change which increased the profits in smelting so largely and rapidly that other smelters hastened to adopt similar methods.

Both Queen's University and McGill University conferred the degree of LL. D. on Dr. Douglas, and he was the recipient of the gold medal of the Institution of Mining and Metallurgy, as well as the John Fritz Medal, which was awarded to him for notable achievements in mining, metallurgy, education and industrial welfare.

Dr. James Douglas

His writings include a long list of articles on mining, metallurgy and railroads, besides several important historical volumes.

ANNUAL REPORT OF THE SECTIONS ACTIVITIES

The year just closed has been marked by progress in the development of the Sections, both in strengthening the local organizations and in mutual service between the parent body and the Sections.

Several innovations have contributed to this progress. The new By-Laws, approved by the Council Meeting in October and published in the November issue of The Journal, govern the activities of each Section to the extent of insuring that its procedure is in conformity with the Constitution of the Society. They leave each Section free to carry out the details of its coöperative work with other societies' sections and its activities of local interest.

At the Annual Meeting in December 1917 the importance of the Sections received official recognition in the first Sections' Session. Delegates from each Section gave a three-minute talk, followed by a general discussion. Many interesting suggestions for development were given at the Sections Session of the Annual Meeting. The possibilities for increasing the membership of the Society through the Sections seemed very practicable. The mechanical engineer, whose work is most often in the industries, is in the forefront of industrial life at this time, and the number of men in this profession is increasing rapidly. At the Spring meeting the Sections Conference contributed still further toward carrying out the ideas evolved in December, and in giving national impetus to the Society's plans for speeding up war industries. An amendment to the Constitution of the Society whereby the voting membership would elect the Nominating Committee, using the organizations of the Sections to effect the election, is a further step in democracy in the Society and was presented at the Spring meeting.

The plan of the Sections Committee of holding its meetings in cities where there are Sections of the Society and where they can get in direct touch with some of the Sections has also been a strong factor in keeping the Sections closely in touch with the Society. Meetings of this kind have been held in Bridgeport, St. Louis, Milwaukee, Chicago, Detroit and Philadelphia during this year.

The first state Section has been organized this year in Connecticut and includes branches in Bridgeport, Hartford, Meriden, New Haven and Waterbury.

Work Undertaken this Year

While the work undertaken in the different Sections has been quite varied, the dominant idea has been that the only worth-while activities were those relating to the war. The

part taken by the engineering profession in local activities of all kinds this year is noteworthy and in line with the enlarged field for engineering as it has been recently outlined. In Atlanta the influence of the local Section brought about the establishment of an advisory board of consulting engineers for the city, thus raising the engineering department beyond the reach of politics. This Section was also instrumental in getting a department of mechanical engineering for the city of Atlanta, which is believed to be the only city in the United States with such a department. In Philadelphia, one of the Sections papers dealt with a mathematical analysis of the Federal Income Tax Law, in which the defects of this law were clearly set forth; this is an interesting example of the engineer's application of his principles to the broader problems of life. The Baltimore Section has been recognized by the Fuel Administration and one of its committees asked to work on material for that adminstration. Baltimore has also given considerable discussion to the subject of economies in the canning business, which is one of Maryland's most important industries; this subject has been discussed from the standpoint of savings in the actual handling of the material to be preserved as well as in the fuel and equipment of the plants. In Detroit the problem of technical education for women has been given considerable attention and a movement set on foot to interest other localities and colleges in this work. The New York Section has discussed the question of labor turnover, thus recognizing the fact that the engineer is the connecting link between labor and capital in a large part of the industries of the country. The non-essential industries have also formed the subject of one meeting of the New York Section, in the discussion of which a resolution was passed to the effect that the Society organize to develop the use of any of the available equipment and working forces of plants not engaged directly in manufacturing war necessities.

SECTIONS AND THE JOURNAL

The Sections Committee has been desirous that the Sections should contribute a share of papers for publication in THE JOURNAL, and to that end requested that each Section submit two papers to the Publication Committee each year. Sixteen papers given at Section Meetings have been published this year. A splendid suggestion in this regard was made at the Sections Session of the Annual Meeting, which was to assign a subject to two or three Sections where that topic is of special local interest; for example, the Boston, Chicago, San Francisco and New Orleans Sections might work up a symposium on shipbuilding. It was felt that the Sections might contribute important aid to the country in this way.

In this connection, the Committee also recommended that something be done in the line of research work, the importance of which at this time is urged upon us by the action of our Allies in this direction. Many of the Sections have appointed committees to give special attention to research work in connection with local colleges and industries.

SECTIONS AND VISITS OF OFFICERS

In the fall of 1917 President Hollis visited the Sections at St. Louis, Los Angeles and San Francisco, and spoke on behalf of the Society at El Paso, Seattle and Portland. At the same time the Sections Committee was meeting with the Sections of the Middle West.

Secretary Rice's visits to a large number of the Sections are believed to have been extremely valuable in correlating the war activities which the Society can carry on only through the medium of its Sections. All the Sections presented a patriotic atmosphere, and everywhere the enormous part played by the engineers in war activities was most striking. Mr. Rice or Mr. Hartford attended meetings at Indianapolis, Cincinnati, New Orleans, Chicago, Toronto, Detroit, Bridgeport, Meriden, New Haven, Boston, and a joint meeting at Birmingham of the Atlanta and Birmingham Sections, besides attending meetings of engineers at Toledo, Dayton and Duluth. In all localities it was the consensus of opinion that meetings of engineering organizations are well worth while at this time.

The Council visited the Chicago Section on November 16, and the Philadelphia Section on April 23, holding its regular monthly meetings at those respective places and times. On each occasion the Council attended the meeting of the Section, in the evening.

COÖPERATION WITH STUDENT BRANCHES

The value of coöperation was well illustrated when the New York Section turned its April meeting over to the Metropolitan Student Branches at Columbia University, New York University, Polytechnic Institute of Brooklyn and Stevens Institute of Technology. This event brought out an attendance of 300 persons in the afternoon, more than 400 at dinner, and between 600 and 700 in the evening.

OUR PRESENT SECTIONS

This year the Society has added the new formation of the Connecticut State Section. The affiliation of the Providence Engineering Society, whose proceedings are reported in THE JOURNAL, still continues a source of mutual benefit. The rest of the Sections are located in Atlanta, Baltimore, Birmingham, Boston, Buffalo, Chicago, Cincinnati, Detroit, Erie, Indianapolis, Los Angeles, Milwaukee, Minnesota, New Orleans, New York, Ontario, Philadelphia, St. Louis, San Francisco and Worcester. A map published in the November issue of THE JOURNAL shows the geographical locations of the Sections to be fairly well distributed over the country. The total number of Sections is now twenty-one, one of which has five branches, and the establishment of several new Sections is contemplated at present.

MEETINGS AND ATTENDANCE

More than 150 meetings have been held in the various Sections this year, all of which have been reported in THE JOURNAL. The Buffalo Section holds weekly meetings, and Indianapolis reports one all-day session with morning, afternoon and evening sessions. The reports show the various meetings to have been very well attended. At Meriden over 175 engineers were present at the June meeting; 200 attended in Bridgeport, and in Boston more than 400 gathered at one meeting in June.

NEW RECORD BOOK

A new record book has been sent to all local sections in order to assist the secretaries of the various Sections in keeping their records. This is of value in systematizing and simplifying the routine work of the Sections and should allow more time to be spent in the more important work of the Sections—that of preparing, selecting and reporting the papers of the meetings. Another good feature of the book is the information concerning other Sections, which is especially valuable at this time when we are engaged in war work. The Committee on Sections would be glad to receive suggestions from members regarding any additions or alterations to this book.

Detailed annual reports from each Section will be published in the September and subsequent issues of THE JOURNAL.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by August 15 in order to appear in the September issue.

CHANGES OF POSITION

WILLIAM F. PARISH, formerly aeronautical mechanical engineer, Signal Corps, Equipment Division, Specification Section, has assumed the duties of chief of Oil and Lubrication Branch of the Supply Section of the Department of Military Aeronautics.

F. RAYMOND JACKSON has severed his connections with the firm of J. E. Sirrine, mill engineer and architect of Greenville, S. C., and has accepted a position in the mechanical section, department of concrete ship construction, of the Emergency Fleet Corporation, U. S. Shipping Board, Philadelphia, Pa.

DAVID S. WEGG, until recently manager of the Telluride Realty Company, Salt Lake City, Utah, is serving as supervising inspector of ordnance material in the Chicago district, with headquarters at the plant of the Standard Steel Car Company in Hammond, Ind.

C. B. BANCH has accepted a position with the U. S. Steel Corporation, ordnance department, Ambridge, Pa., as designing engineer. He was formerly in the employ of Corrigan, McKinney and Company, of Cleveland, Ohio, in a similar capacity.

CHARLES F. MERRILL has resigned his position as chief engineer of the James Hunter Machine Company, North Adams, Mass., to take a position in the Southern sales department of the Draper Corporation at Atlanta, Ga. Mr. Merrill was for several years connected with the engineering department of the Draper organization at Hopedale, Mass.

LEWIS S. MAXFIELD has resigned from the motive-power department of the Interborough Rapid Transit Company and New York Railways Companies, New York, to become associated with the Nate-Earle Company, engineering contractors of the same city, as assistant engineer.

W. HERMAN GREUL, for some years identified with the Otis Elevator Company, New York, has been made president of the Standard Plunger Elevator Company, Worcester, Mass.

ARTHUR SEUBERT, formerly instructor in mechanical engineering, Polytechnic Institute of Brooklyn, Brooklyn, N. Y., has entered the service of the New York Edison Company, New York, in the capacity of assistant to mechanical engineer.

CHARLES W. VOCKE, formerly mechanical engineer with the Nitrogen Fixation Corporation, New York, has become affiliated with the National Aniline and Chemical Company, Wappingers Falls, N. Y.

AUGUSTUS H. LANE has left the employ of the Grant Hammond Manufacturing Corporation, of New Haven, Conn., and has taken a position in the engineering department of the Government at Watervliet Arsenal.

FRANCIS L. BARSTOW has become affiliated with the Falulah Paper Company, Fitchburg, Mass. He was formerly connected with the Worden-Allen Company, Chicago, Ill.

WILLIAM R. CRUTE has resigned his position of chief engineer of the Champion Fiber Company, Canton, N. C., to accept the position of aero mechanical engineer, naval aircraft factory, Navy Yard, Philadelphia, Pa.

HARRY B. CHAPMAN, formerly manager of the Chapman Engineering Company, Texas City, Tex., has entered the service of the Westinghouse Electric and Manufacturing Company Machine Works, East Pittsburgh, Pa.

JOHN W. KITTREDGE, until recently designer with the Firestone Tire and Rubber Company, Akron, Ohio, has accepted a similar position with the Diamond Match Company, of Barberton, Ohio.

JOSEPH E. SHEEDY, assistant manager, Seattle Construction and Dry Dock Company, Seattle, Wash., has become associated with the Erickson Engineering Company of the same city.

JOSEPH H. CHEETHAM, formerly chief mechanical engineer, McNab and Harlin Manufacturing Company, Paterson, N. J., has assumed the duties of superintendent of the Kunkle Valve Company, Fort Wayne, Ind.

C. EDWIN CLARKE has assumed the duties of master mechanic, Saucon plant of the Bethlehem Steel Company, Bethlehem, Pa. He was formerly affiliated with the Wilmington Steel Company, Wilmington, Del., in the capacity of chief engineer.

JOSEPH J. NELIS, formerly with the Babcock and Wilcox Company, Cincinnati, Ohio, has accepted a position with the U. S. Shipping Board, Emergency Fleet Corporation, Technical Division, Philadelphia, Pa. Mr. Nelis will be engaged in boiler work.

ANNOUNCEMENTS

JOSEPH N. MAHONEY has severed his relations with the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., to take up the practice of consulting mechanical and electrical engineer, with offices in New York. He will specialize in the design and application of railway brake and control apparatus of the mechanically, electrically or pneumatically operated forms; also industrial and power electrical control and switching equipment.

FREDERIC F. GAINES, superintendent of motive power, Central of Georgia Railway, Savannah, Ga., has become a member of the Board of Railroad Wages and Working Conditions, with headquarters at Washington, D. C.

B. M. BAXTER, for nine years associated with H. B. Prather, consulting engineer of Cleveland, has severed his connection with Mr. Prather and has opened an office in the same city to conduct a consulting engineering business in steam-power-plant and mill-building work, specializing in paper-mill engineering.

OLIVER C. IRWIN, until recently associated with the Frick Company of New York, as refrigerating engineer, has opened an office at 291 Broadway, New York, under the firm name of O. C. Irwin and Company, Engineers.

R. SANFORD RILEY, president of the Sanford Riley Stoker Company, Ltd., Worcester, Mass., and of the Murphy Iron Works, Detroit, Mich., has been requested by the Emergency Fleet Corporation to arrange for supervision of trial trips of all merchant ships now being turned out in this country. He has undertaken the organization of this department for the Emergency Fleet Corporation, but has an arrangement by which he will retain supervision of his other interests during his connection with the Corporation. Before going into the stoker business, Mr. Riley had an extensive experience in marine engineering and shipbuilding. His qualifications were called to the attention of Mr. Charles M. Schwab by former shipbuilding associates, which resulted in his call to service.

F. L. CHURCHILL has enlisted in the service of the U. S. Shipping Board for the duration of the war, and is now stationed on the S. S. *Suriname*. He was formerly affiliated with the Fafnir Bearing Company, of New Britain, Conn.

A. C. THOMAS has assumed the duties of equipment superintendent, liquid air department of the Air Nitrates Corporation, Mussel Shoals, Ala.

John R. Shea left on July 15 for Tokyo, Japan, to represent the Western Electric Company's manufacturing interests there. He was formerly connected with the Chicago plant of the company, as head of the production methods division.

William F. Schweigert has been elected secretary of the Niagara Machine and Tool Works. He will continue to give special attention to the sales department by attending to the most important work on the road. Mr. Schweigert has been affiliated with the company for 30 years.

Miller Reese Hutchison, associated for several years as chief engineer of the laboratory in West Orange with Thomas A. Edison, President of the Naval Consulting Board, has resigned from the Edison interests to devote his entire time to the prosecution of the war. Dr. Hutchison is a member of the Naval Consulting Board.

Harry Cowen, until recently assistant engineer of car equipment, Interborough Rapid Transit Company, New York, has been transferred to the position of general foreman of the mechanical department of the New York Railways Company, New York.

Warren C. Drake, for the past 12 years connected with the stoker-engineering department of the Westinghouse Electric and Manufacturing Company, New York, has resigned this position. He has entered into partnership with H. S. Sleicher, and has opened an office in New York, under the firm name of Sleicher and Drake, for the handling of power-plant equipment.

Joseph Breslove, until recently sales engineer with the Allis-Chalmers Manufacturing Company, Pittsburgh, Pa., has opened an office in the same city, and will carry on a general consulting practice, specializing in power-plant work.

Frank C. Turner, formerly representative of the Southern Wheel Company, Birmingham, Ala., has assumed the duties of vice-president of the same company, with headquarters at St. Louis, Mo.

Max K. Grossheim is now in charge of the engineering department of L. O. Koven and Brothers, boiler makers and engineers, of Jersey City, N. J. His former duties with this concern were those of designer.

APPOINTMENTS

Col. Charles C. Jamieson, Lieut-Col. H. B. Hunt and Lieut-Col. W. P. Barba are among the members of a board appointed by General C. C. Williams, Acting Chief of Ordnance, to represent the Ordnance Department in the preparation and approval of plans for the construction of the Neville Island plant for heavy cannon and projectiles to be constructed by the United States Steel Corporation. The board will coöperate with the corporation in the planning, construction and operation of the plant.

H. H. Esselstyn, associated with the U. S. Shipping Board, Emergency Fleet Corporation, has been appointed Commissioner of Public Works, Detroit, Mich., and will assume his office when he obtains his release from the U. S. Shipping Board. Mr. Esselstyn is senior member of the firm of Esselstyn, Murphy and Hanford, of the same city.

John W. F. Bennett, member of the firm of Goodrich, Hoover and Bennett, consulting engineers of New York, has been appointed Major in the Construction Division of the Quartermaster's Corps, National Army.

Ross Anderson has been appointed manager at the Accessory Plant of the American Locomotive Company, Richmond, Va. Mr. Anderson was superintendent at their Pittsburgh plant for the last year, and prior to that manager of the Poole Engineering and Machine Company, Baltimore, Md.

Albert G. Suttill has been appointed inspector for the Merchant Shipbuilding Corporation, of Bristol, Pa., in charge of the Boston district.

George R. Henderson has been appointed Administrative Engineer for Pennsylvania, under the Federal Fuel Administration.

ROLL OF HONOR

Abernethy, A. A., U. S. Naval Reserve Force, in training at U. S. Steam Engineering School, Hoboken, N. J.

Allison, John R. A., Second Lieutenant, Engineer Officers' Reserve Corps, General Engineer Depot, U. S. Army, Field Inspection Service.

Arnold, John A., Camp Meade, Md.

Barba, W. P., Lieutenant-Colonel, Ordnance Department, N. A., Ordnance Department Board of Construction of U. S. Steel Corporation Plant.

Barton, Warren H., Co. H, 2d Engineers' Regiment, Camp Humphrey, Va.

Bates, D. M., Major, U. S. Army.

Bennett, John W., Major, Construction Division, Quartermaster's Corps, N. A.

Berliner, R. W., Major, Quartermaster's Corps, U. S. Army.

Budwell, Leigh, Second Lieutenant, Engineer Officers' Reserve Corps, 61st Engineers, Fort Benjamin Harrison, Ind.

Childs, Harold P., First Lieutenant, Truck Co. No. 2, First Battalion, 23d Regiment Engineers, American Expeditionary Forces, France.

Coleman, R. J., First Lieutenant, Ordnance Officers' Reserve Corps, Ordnance Department, American Expeditionary Forces, France.

Cox, Abraham B., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, American Expeditionary Forces, France.

Derry, Gardner C., Ensign, U. S. Naval Reserve Force, U. S. Naval Academy, Annapolis, Md.

Dilts, Frank B., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army, stationed at Watervliet Arsenal, N. Y.

Drake, Charles L., First Lieutenant, Ordnance Officers' Reserve Corps, Sandy Hook Proving Ground, Fort Hancock, N. J.

Edimann, Frank L., Ensign, U. S. Naval Reserve Force, Aviation.

Frankel, Monroe J., 4th Battery, Field Artillery, Officers' Training Camp, Camp Zachary Taylor, Ky.

Fuhr, Harry E., Ensign, U. S. Navy.

Gates, S. J., Captain, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.

Haney, James B., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army, American Expeditionary Forces, France.

Hunter, H. C., Co. C, 304th Battalion, N. A., Camp Colt, Gettysburg, Pa.

Irwin, K. M., U. S. Naval Reserve Force.

Kemble, Parker H., Lieutenant, U. S. Naval Reserve.

McLindie, First Lieutenant, Ordnance Officers' Reserve Corps, Rock Island Arsenal, Rock Island, Ill.

Marshall, Waldo H., Colonel, Ordnance Officers' Reserve Corps, Production Division, Ordnance Department, U. S. Army.

Mayer, James Leo, Lieutenant, 109th Engineers, Camp Cody, N. M.

Myers, Curtis C., Captain, Ordnance Officers' Reserve Corps, U. S. Army.

Peter, Albert G., First Lieutenant, Ordnance Officers' Reserve Corps, stationed at the Philadelphia District Ordnance Office.

Rosenthal, Emanuel, Sergeant, Co. D, 19th Platoon, 56th U. S. Engineers, American Expeditionary Forces, France.

Ruppel, Richard L., Captain, Quartermaster's Corps, N. A., Construction Division.

Sanders, Walter C., Lieutenant, Battery F, 64th Heavy Artillery (C. A. C.), American Expeditionary Forces, France.

Shearer, David R., First Lieutenant, Aviation Section, Signal Officers' Reserve Corps, Finance Department, Approvals Section, U. S. Army.

Sladky, A. C., Captain, Ordnance Officers' Reserve Corps, Production Division, Ordnance Department, U. S. Army.

Swift, Henry, First Lieutenant, Ordnance Officers' Reserve Corps, Inspection Division, Ordance Department, U. S. Army.

Taylor, Charles Fayette, Lieutenant (Junior Grade), U. S. Naval Reserve Flying Corps, stationed at Washington Navy Yard.

Tayman, George S., Chemical Section, Division of Mechanical Research, N. A., American University, Washington, D. C.

Teague, Newton N., Second Lieutenant, Aero Engineer Officer, Air Service, N. A., U. S. Army.

Treuhaft, A. A., Ordnance Engineering School, Aberdeen Proving Grounds, Md.

Wagenseil, E. W., Lieutenant (Junior Grade), U. S. Naval Reserve Force, Naval Reserve Flying Corps Repair Base, France.

Warner, First Lieutenant, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.

Woobank, Wilfred, Private, Meteorological Section, Signal Corps, U. S. Army, Texas A. & M. College, College Station, Tex.

Wood, C. E., Chemical Warfare Section, N. A.

Worthen, Charles B., Second Lieutenant, Military Aeronautics Division, U. S. Army.

Yardley, R. W. E., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER SEPTEMBER 10

BELOW is the list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 253.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by Sept. 10, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about Oct. 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

RICHARDSON, WILLIAM, JR., Construction Engineer, Tennessee Coal, Iron & Railroad Co., Ensley
WATSON, CHARLES E., Chief Engineer, Alabama Dry Dock & Shipbuilding Co., Mobile

California

JOHNSSON, MONS J., Outside Superintendent, Pacific Portland Cement Co., Cement
MEESE, CONSTANT, President and Directing Manager, Meese & Gottfried Co., San Francisco
SCHWEITZER, R. R., Vice-President and General Manager, Western Machinery Co., Los Angeles

Colorado

BIER, PETER, Mechanical Engineer, Construction Department, Great Western Sugar Co., Denver
GILBERT, GEORGE T., Consulting Engineer, Denver
LESTER, WILLIAM, General Superintendent and Chief Engineer, Vulcan Iron Works, Denver

Connecticut

ARCHER, SYLVANUS, Assistant Superintendent, Bank Lock Dept., Yale & Towne Mfg. Co., Stamford
BARNES, FRED L., Estimator and Salesman, Eastern Machinery Co., New Haven
CLEVELAND, FRANK W., Assistant to Superintendent of Equipment, Pratt & Whitney Co., Hartford
COLVIN, BENJAMIN J., Power Engineer, Sidney Blumenthal & Co., Inc., Shelton
CROCKER, JOHN F., Comptroller, Bridgeport Brass Co., Bridgeport
LINTON, SAMUEL A., Foreman, Pratt & Whitney Co., Hartford
MARSHALL, CARL, Welfare Manager, Pratt & Whitney Co., Hartford
VALENTINE, AUGUST L., Superintendent, Pratt & Whitney Co., Hartford

Delaware

BARSTOW, JOHN S., Engr., E. du Pont de Nemours & Co., Wilmington
BERGLAND, WILLIAM S., Engineer, E. I. du Pont de Nemours & Co., Wilmington
LAIRD, WALTER J., Construction Engineer, du Pont Co., Wilmington
NORBOM, TORLEIF S., Superintendent of Marine Machinery, The Pusey & Jones Co., Wilmington

District of Columbia

BROOKS, HENRY W., Mechanical Engineer, U. S. Ord. Dept., Inspc. Div., Washington
CHAPLIN, MERLE P., 1st Lieutenant, Engineer R. C., Engineer Branch, Motor Transport Service, Unit F, 7th Wing, Washington
DAHLQUIST, CHARLES S., Major, Q. M. C. N. A., Motor Transport, Supervisor of Inspection, Inspection Division, Washington
HARRIS, GLENN B., Gauge Engineer, Inspection Div., Ord. Dept., Washington
McCONNELL, JAMES W., Master Mechanic, Torpedo Tube Shop, Washington Navy Yard, U. S. Naval Gun Factory, Washington

Florida

RAGONNET, EUGENE L., Mechanical Engineer, Cuba Cane Sugar Corp., Miami

Georgia

TUFTS, R. BARRY, Engineer and Contractor, Private Practice, Atlanta

Illinois

BENNETT, WILMER C., Structural Engineer, Private Practice, Chicago
COLE, AUSTIN, President and General Manager, Western Valve Bag Co., Chicago
FRYE, RAYMOND P., Chief Draftsman, Amalgamated Machinery Corp., Chicago
GOOLEY, JOSEPH E., Sales Engineer, The Imperial Brass Mfg. Co., Chicago
PEACOCK, CHARLES M., Mechanical Engineer, Equipment, D. A. Wright, Chicago
WACHS, CHARLES L., Vice-President, The E. H. Wachs Co., Chicago

Indiana

BAYLOR, CHARLES A., Superintendent, Great Western Mfg. Co., La Porte
BERTSCH, LAWRENCE H., Vice-President and Chief Engineer, Bertsch & Co., Cambridge City
JACOB, WILLIAM, Chief Car Draftsman, C. C. C. & St. L. Ry., Indianapolis
LEWIS, EDWIN H., Assistant to Inspection Manager, Inspection Div., Ordnance Dept., Standard Steel Car Co., Hammond
LUTEN, DANIEL B., Designing and Consulting Engineer, Private Practice, Indianapolis
PILKINGTON, ROBERT G., Automotive Engineer, Dodge Mfg. Co., Mishawaka

Kentucky

MOORE, CLARENCE S., Chief Engineer, Lex. Laundry Co., Lexington

Louisiana

GRANT, ARTHUR A., New Orleans Mgr., Freeport & Mexican Fuel Oil Co., New Orleans

Maryland

MORGAN, MERTON W., Chief Draftsman, Poole Engineering & Machine Co., Baltimore
WILLIAMS, JESSE W., Master Mechanic, By Product Coke Oven Dept., Bethlehem Steel Co., Sparrows Point

Massachusetts

AMES, BRADFORD L., President, Monarch Soot Remover Co., Boston
BALLENTINE, JOEL E., Mechanical Engineer, A. C. Lawrence Leather Co., Peabody
BENGSTON, CARL, Power Engineer, Norton Co., Worcester
CHASE, ALBERT M., Draftsman, C. W. Praray, Mill Engineer, New Bedford
COPPUS, FRANS H. C., President, Treasurer, Coppus Engineering & Equipment Co., Worcester
DOE, THOMAS B., General Manager, United States Cartridge Co., Lowell
FARNHAM, WALTER E., Head of Engineering Department, New Bedford Textile School, New Bedford
GOLDSMITH, GEORGE H., General Superintendent, James Hunter Machine Co., North Adams
GOUGH, CHARLES M., Construction Department, Watertown Arsenal, Watertown
HOWARD, HENRY F., Engineer, Worcester Mfg. Co., Worcester
HUGHES, JOHN L., Designing and Development Engineer, General Electric Co., Pittsfield
ISLEY, GEORGE H., Mechanical Engineer, Private Practice, Worcester
LAWRENCE, HOWARD B., Engineer, John A. Stevens, Consulting Engineer, Lowell
LOWELL, KARL P., Mechanical Engineer, Fred T. Ley & Co., Inc., Springfield
MAIN, CHARLES R., Special Assistant, Charles T. Main, Engineer, Boston
PENNEY, LOREN W., Mechanical Engineer, Saco-Lowell Shops, Newton Upper Falls
RAMSDELL, THOMAS S., Constructing and Operating Engineer, Monument Mills, Housatonic
SMALL, ERNEST M., Engineering Draftsman, Power House Design, Edison Ill. Co., Boston
SYME, JAMES M., Superintendent, Brown Bag Filling Machine Co., Fitchburg
SZEPESI, EUGENE, Senior Engineer, Cooley & Marvin Co., Boston
WARFIELD, GEORGE L., Superintendent, Thorndike Co., Thorndike

WHEELER, Benjamin A., Chief Draftsman, Whitcomb-Blaisdell Machine Tool Co., Worcester
WILSON, Henry L., Mechanical Engineer, Atlantic Dyestuff Co., Boston

Michigan

FITZGERALD, John W., Engineer, L. A. Young Industries, Inc., Detroit
GIFFORD, W. Arthur, President and Manager, Gifford Engine Co., Lansing
McDONALD, William F., Heating Engineer, William F. McDonald Co., Detroit
NESBITT, James W., Assistant Mechanical Superintendent, Packard Motor Car Co., Detroit
POULSEN, Eugene, Chief Draftsman, The Prescott Co., Menominee
RADFORD, Fred L., Chief Draftsman, Reo Motor Car Co., Lansing

Minnesota

UHL, Willard F., Sales Engineer, Private Practice, Minneapolis

Missouri

MALLINCKRODT, Edward, Jr., Manufacturer, Mallinckrodt Chemical Works, St. Louis

Nevada

CAFFEREY, Willis G., Electrical Engineer, Nevada State Hospital for Mental Diseases, Reno

New Jersey

BARRI, Joel G., Field Mechanical Engineer, c/o T. A. Gillespie Loading Co., South Amboy
CAREW, William A., General Superintendent, Morgan Engineering Co., Jersey City
CARLISS, Oswald T., Chief Inspector of U. S. A. Ordnance, National Vitaphone Corp., Plainfield
CHASE, George C., President, Chase Adding Machine Corp., Orange
FRENCH, Charles M., 1st Lieutenant, Engineers R. C., 34th Engineers, Camp Dix
HOHL, George L., Mechanical Engineer, Any Package Wrapping Machine Co., Newark
NILIUS, Bruno, Assistant Chief Mechanical Engineer, American Can Co., Edgewater
VANDERHOOF, Arnold H., Ensign, U. S. N. (Retired), Officer in Charge, U. S. Naval Radio Station, New Brunswick
WARNER, Murray, in Charge of Utilities, Camp Dix

New York

BARRY, Joseph C., Mechanical Draftsman, N. Y. Edison Co., New York
BERMAN, Louis K., Vice President, Raisler Heating Co., New York
BISHOP, Clarence A., President and General Manager, The Bishop Calculating Recorder Co., New York
CARL, Fred H., Engineer, Westinghouse Church, Kerr & Co., New York
CASEY, Albert O., Engineer on Telephone Apparatus, Western Electric Co., Inc., New York
CUNDALL, Robert N., Consulting Engineer, Cundall & Powell, Buffalo
DIBERT, Herbert M., General Sales Manager, W. & L. E. Gurley, Troy
EMMONS, Charles L., Factory Manager, Aeolian Co., New York
GAZIN, Lewis M., Engineer, Federal Light & Traction Co., New York
GLATHE, Bernhard, Chief Engineer, The Cuban American Sugar Co., New York
GLENDENNING, William J. A., Consulting Engineer, Mech. Rubber Goods & Asbestos Packing, New York
HAMMOND, John W., Secretary, Lake Erie Engineering Works, Buffalo
JENNINGS, Wilfred B., Works Engineer, Worthington Pump & Machinery Corp., Buffalo
LUTHER, George W., Mechanical Engineer, The Luther Mfg. Co., Olean
MURRAY, Howard J., Electrical Engineer, Gibbs & Hill, New York
OLSON, John H., Engineer, M. H. Treadwell Co., New York
PATTERSON, J. Clifford, Testing Department, The Solvay Process Co., Syracuse
PHILIPS, William D., Manager of Engineering and Sales, A. S. Nichols Co., New York
ROBLIN, Wilmot H., Inspector of Ord., U. S. O. D., Watervliet Arsenal, Watervliet
SEABROOKE, William L., William L. Seabrooke, Chemicals, New York
SHARP, John, Mechanical Engineer, Ferguson Steel & Iron Co., Buffalo
SIMMONDS, Philip R., Eastern Sales Manager, Kernchen Co., of Chicago, New York
SLOCUM, Herbert J., Jr., President, Slocum, Avram & Slocum, Inc., New York
SMITH, Engineer, United Gas & Electric Engineering Corp., New York
STEELE, Hugh E., Manager West Coast Machinery Business, W. R. Grace & Co., New York
WETMORE, Miner P., Treasurer and General Manager, The Hygrade Engineering Co., New York
WHITE, Robert H., Engineer of Construction, American Locomotive Co., Schenectady

Ohio

BRADLEY, W. H., Vice-President and General Manager, Bedford Coal Co., Coshocton
HUBER, Frank W., Assistant Superintendent, Forge & Foundry Dept., American Rolling Mill Co., Middletown
MORRIS, John F., Superintendent of Maintenance, Whitaker Glessner Co., Portsmouth
WILSON, Alexander M., Professor Electrical Engineering, University of Cincinnati, Cincinnati
WILSON, Harland H., Designing Engineer, McKinney Steel Co., Cleveland

Oregon

BALE, Charles W., Chief Engineer, Albina Engine & Machine Wks., Inc., Portland

Pennsylvania

ALBRECHT, Albert J., Draftsman, Midvale Steel & Ord. Co., Philadelphia
BENNETT, William H., Rolling Mill Supt., Clairton Wks., Carnegie Steel Co., Clairton
BENSON, Harry L., General Foreman, Machine Shop, The Midvale Steel Co., Philadelphia
CHAPMAN, Washington H., Engineer, U. S. Ship Building Emergency Corp., Philadelphia
CUPITT, A. Warren, Equipment Engineer, Midvale Steel Co., Nicetown
GECK, Albert A., Superintendent, Colburn Machine Tool Co., Franklin
HARRIS, Henry S., Sales Engineer, Ingersoll Rand Co., Philadelphia
HARRIS, Leslie M., Assistant to Vice-President, American Engineering Co., Philadelphia
HATCH, Charles W., Assistant Chief Draftsman, American Sheet & Tin Plate Co., Pittsburgh
HENDERSON, Richard, Works Engineer, Stanley G. Flagg & Co., Pottstown
HOCKENSMITH, Wilbur D., General Manager and Vice-President, Hockensmith Wheel & Mine Car Co., Penns Station
JAUSS, August C., Chief Draftsman, Artillery Dept., Midvale Steel & Ordnance Co., Nicetown
LAUBENSTEIN, Albert R., Manager and Treasurer, Laubenstein Mfg. Co., Ashland
LYONS, Robert J., Assistant Purchasing Officer, Emergency Fleet Corp., Philadelphia
MATTHEWS, John J., Director of Shops, Swarthmore College, Swarthmore
MEYER, Carl F., Sales Manager, Landis Machine Co., Waynesboro
MUNZ, William, Mechanical Engineer, Ballinger & Perrot, Philadelphia
OBERSTADT, Carl, Mechanical Expert and Efficiency Engineer, Iron City Products Co., Pittsburgh
OSWALD, Harry A., Assistant General Superintendent, Naval Aircraft Factory, Navy Yard, Philadelphia
OTTO, William F., Sales Engineer, Eynon-Evans Mfg. Co., Philadelphia
ROBERTS, William E., Lieutenant, U. S. N. R. F., Asst. Genl. Supt., Naval Aircraft Factory, Navy Yard, Philadelphia
SCOTT, C. Linford, General Superintendent, Harrisburg Mfg. & Boiler Co., Harrisburg
TOLSTED, Elmer B., Engineer, Independence Bureau, Philadelphia
VAUCLAIN, Jacques L., an Assistant to the Vice-President, The Baldwin Locomotive Works, Philadelphia

Rhode Island

OSTBY, Raymond E., General Superintendent, Ostby & Barton Co., Providence

South Carolina

KENNEDY, Alfred D., Vice-President and General Manager, American Machine & Mfg. Co., Greenville

Texas

STEVENS, Harry L., Consulting Refrigerating Engineer & Supply Co., El Paso

Virginia

HILDEBRAND, Clarence K., Designer and Southern Rep., The Ludington Cigarette Mch. Co. of Waterbury, Conn., Salem

Washington

BALLWEG, John H., Electric Engineer, U. S. Spruce Cut Up Mills, Vancouver

Wisconsin

ATHERTON, Donald H., Instructor Mechanical Engineering, University Extension Div., University of Wisconsin, Madison
RICHARDS, Forest A., Engineer for Mr. Edward Hutchens, Consulting Engineer, Eau Claire
SPRINK, Isaac W., Special Inspector and Investigator Engineering Department, Four Wheel Drive Auto Co., Clintonville
ZANTOW, Henry C., Assistant to Wisconsin State Power Plant Engineer, Mr. John C. White, Madison

Canada

HODGE, Charles A., Instructor, Nova Scotia Technical College, Halifax, N. S.
LANG, James, Estimating and Contracting Engineer, John Inglis Co., Ltd., Toronto
VIBERG, Ernest R., Mechanical Engineer, Canadian Car & Fdy. Co., Ltd., Montreal

England

FOWLER, Sir Henry, Lieutenant-Colonel, Royal Flying Corps; Superintendent, Royal Aircraft Factory, Derby

Norway

RIDDERVOLD, L. Dahl, Vice-President and Manager, Gustav Nielsen A. S. Toldbedgaten, Christiania

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

California

RIX, HAROLD P., Machinery Merchant, Vice-President, Rix Compressed Air & Drill Co., San Francisco

Delaware

HATCH, JOSEPH R., Fire Protection Engineer, Old Hickory Works, E. I. du Pont de Nemours & Co., Wilmington

Illinois

MILLER, PAUL B., Chief of Section, Apparatus Drafting Dept., Western Elec. Co., Inc., Hawthorne

Iowa

PRAY, JOHN W., Superintendent, City Water Department, Dodge

Massachusetts

CANNITY, ERNEST, Chief Draftsman, Hunter Machine Co., North Adams

WEBSTER, OSCAR A., General Foreman, Machine Shop, Stafford Co., Readville

WHITCOMB, FORREST R., Superintendent, American Radio & Research Corp., Medford, Hillside

New Jersey

GORDON, ROBERT J., Power Engineer, Hercules Powder Co., Kenvil

WHITMORE, RALPH D., Supervising Engineer, American Standard Metal Products Corp., Paulsboro

WOEHL, FRANK, Draftsman and Designer, Babcock & Wilcox Co., Bayonne

New York

DOWNS, CHARLES L., Captain, Army Inspector of Ordnance, U. S. A., Artillery and Artillery Ammunition, New York Air Brake Co., Watertown

Ohio

CLASGENS, JOSEPH H., Assistant Superintendent, The J. & H. Clasgens Co., New Richmond

GIBSON, WILLIAM A., Mechanical Engineer, The Aluminum Castings Co., Cleveland

KER, HENRY W., Sales Manager, Wapakoneta Machine Co., Wapakoneta

WADSWORTH, HOWARD L., Manager, American Foundry Equipment Co., Cleveland

Pennsylvania

COHN, HERBERT A., Chief Draftsman, Works Power Engr. Div., Westinghouse Elec. & Mfg. Co., E. Pittsburgh

FERNSLER, PENROSE A., 135 So. 11th St., Lebanon

GODWIN, ROY M., Mechanical Engineer, Barrett Co., Philadelphia

LEROY, LEO F., Leading Locomotive Draftsman, Designer and Checker, Mechanical Department, Erie R. R., Meadville

OGLE, GEORGE M., General Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh

SEVERN, ARTHUR B., Equipment Pilot Engineer, Baltimore & Ohio R. R., Pittsburgh

Wisconsin

HAY, EARL D., Professor of Drawing and Machine Design, State Normal School, Oshkosh

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Colorado

BYERS, HARRY R., with Babcock & Wilcox Co., Denver

Connecticut

CARVETTE, CHARLES W., Military Engineer, Remington Arms Union Metallic Cartridge Co., Bridgeport

McGARVEY, JOSEPH T., Sub-Inspector of Ordnance Navy Dept., American & British Mfg. Co., Bridgeport

MAC INTYRE, JAMES R., Chief Designer, H. E. Harris Engineering Co., Bridgeport

District of Columbia

HATTON, MERLE W., Mechanical Expert, Chem. Warfare Service, Research Div., American University Experiment Sta., Washington

Illinois

PARMENTER, LAURENCE L., Private, Edgewood Plant, Edgewood Arsenal, Edgewood, Md., Detachment "D" Chicago & N. W. R. R., Chicago

SIMPSON, ARTHUR M., Sales Engineer, Wood Equipment Co., Chicago

WOOD, KENNETH V., Night Enginehouse Foreman, C. C. C. & St. L. R. R. Co., Mt. Carmel

Indiana

MENKE, EDWARD W., Assistant Engineer, United Chemical & Organic Products Co., Hammond

RETTERER, RAY W., Assistant Mechanical Engineer, C. C. C. & St. L. Rwy., Beech Grove

SMITH, DAVID W., Assistant Mechanical Engineer, Rubber Regenerating Co., Mishawaka

Massachusetts

NAKASHIAN, LUKE L., with Jefferies-Norton Corp., Worcester

PALMER, RAYMOND E., Chief Engineer, Construction Div., Kalmus, Comstock & Westcott, Inc., Cambridge

SODERBERG, ROBERT B., Lieutenant Ord. R. C., Army Inspector of Ordnance and Acting Quartermaster for Gray & Davis, Inc., Amesbury

WESLEY, HARRY B., Designing Engineer, Brown Bag Filling Machine Co., Fitchburg

New Jersey

KNOWLES, CHARLES H., Principal Assistant Engineer, The Arnold Co., U. S. General Hospital No. 3, Colonia

New York

CAHILL, JOHN E., JR., Ampudia & Cahill, Industrial Engineers, New York

FISHER, PIERCE H., in Charge Mechanical Development, Medical Research Laboratory, Mineola

McNULTA, J. JOSEPH, Chief Engineer, Vacuum Ash & Soot Conveyor Co., New York

RAYMOND, GEORGE G., Industrial Engineer, Gunn, Richards & Co., New York

SHELDON, WILLIAM M., Mechanical Engineer, Sheldon Co., New York

SMITH, EDWARD J., Foundry Engineer, Ingersoll Rand Co., Painted Post

SPICER, ELMER D., Factory Manager and Chief Engineer, Moore Steam Turbine Corp., Wellsville

THOMSEN, RAYMOND L., Manager of Marine Dept., The Griscom Russell Co., New York

Ohio

BOUGHTON, JAMES A., Chief Engineer Power House No. 2, Goodyear Tire & Rubber Co., Akron

CONSTAM, ALYN F., Construction Engineer, The B. F. Goodrich Co., Akron

CECIL, WILLIAM D., Resident Material Inspector, Baltimore & Ohio R. R., Cincinnati

MACLEAN, ARCHIE A., Engineer of Tests, Ordnance Dept., U. S. A., Standard Parts Co., American B. B. Plant, Cleveland

Oregon

BETHARDS, F. EARL, Efficiency Department, Willamette Iron & Steel Wks., Portland

Pennsylvania

EADES, HERBERT S., Assistant to Mechanical Engineer, American Bridge Co., Ambridge

RAPPAPORT, ARTHUR, Engineering Draftsman, John Lang Paper Co., Philadelphia

Wisconsin

ROBERTS, EARL H., Chief Mechanical Engineer, John Obenberger Forge Co., West Allis

Canada

JARRED, ARTHUR, Superintendent, Smithy, Massey, Harris Co., Ltd., Toronto

FOR CONSIDERATION AS JUNIOR

Connecticut

HOMANN, FREDERICK A., Ensign, Technical Duties, U. S. N. R. F. Dept., Public Works, Naval District Base, State Pier, New London

District of Columbia

BURDICK, THEODORE A., Sergeant 1st Class 437th Engineers, General Engineer Depot, U. S. A., Washington

FERNALD, ERNEST M. Laboratory Assistant Navy Yard, Washington

NOLAN, JAMES B., Warrant Machinist U. S. N., Bureau of Navigation, Washington

Illinois

CARMICHAEL, VICTOR V., Assistant to Superintendent of Power, Aluminum Ore. Co., E. St. Louis

KERR, VOLNEY A., Engineer, Draftsman and Designer, American Well Works, Aurora

SNAPP, HOWARD M., Jr., U. S. Army, A. S. S. C., Science and Research Div., Joliet

TYMESON, CHARLES P., 1st Lieut. Ordnance R. C., U. S. Army, Rock Island Arsenal

Indiana

CORNELL, DANA R., Assistant General Foreman, Heat Treating Dept., Standard Forgings Co., Indiana Harbor

McCRADY, HARRY E., Tool Designer and Checker, Nordyke & Marmon Co., Air Plane Eng. Dept., Indianapolis

Massachusetts

HOPKINS, ETHAN C., Superintendent, Wade Machine Co., Boston

RITCHIE, A. T., Draftsman, Simplex Electric Heating Co., Cambridge

Michigan

ALBINSON, HAROLD A., Machine Designer, Michigan Copper & Brass Co., Detroit

McKENNY, CHARLES A., Sergeant Mechanic, Co. C., 313 Field Signal Battalion, Ypsilanti

Missouri

BALCH, WILLIAM S., Secretary and General Manager, Southwestern Appraisal Co., Kansas City

WEISSBACH, EDWARD A., Mechanical Engineer, Mallinckrodt Chemical Works, St. Louis

New Jersey
- COE, FRANK C., Superintendent and General Manager, C. T. Coe Co., Newark
- NATHAN, WALTER S., Student U. S. N. Steam Engineering School, Hoboken
- SKOOG, R. W., Draftsman, U. S. Navy Dept., N. Y. Shipbuilding Corp., Camden

New York
- BERNNER, MILTON ST. J., Elmhurst
- BEYER, EDMOND P. W., Designer, Gifford-Wood Co., Hudson
- BUCHANAN, EDWARD E., JR., Heat Treatment, Curtiss Aeroplane & Motor Corp., Hammondsport
- CARLISLE, CHARLES A., JR., with Savage Arms Corp., Utica
- RIBEIRO, JOSE DE ASSIS, Calculator, American Locomotive Co., Schenectady
- SIMS, LEWIS R., 1st Lieutenant, Ordnance R. C., Repair Shop Attach., 29th Div., Camp Mills, Mineola
- SMITH, WILLIAM A., Assistant to Educational Director, The Texas Co., New York
- STARLING, H. STANLEY, Assistant Material Inspector, Surveyor at Large, Bureau Veritas, New York
- WALSH, HARRY W., Master Engineer, U. S. Army Engineers, New York
- WALTON-CRANFORD, WILBERT, Erecting Engineer, Shipley Construction & Supply Co., Brooklyn

Ohio
- GWIAZDOWSKI, A. P., Associate Professor of Mechanical Engineering, Toledo University, Toledo
- LEATHERS, H. M., Sales Engineer, Cutler-Hammer Mfg. Co., Cleveland

Oklahoma
- BROOK, CLIFFORD E., Assistant Supt., Gas Pipe Line Dept., Empire Gas & Pipe Line Co., Bartlesville

Pennsylvania
- BODKIN, HARRY G., Tool Designer, Midvale Steel & Ordnance Co., Philadelphia
- CANTER, MAURICE J., Production Engineer, Midvale Steel Co., Philadelphia
- LEVIN, JACOB, Marine Draftsman, American International Shipbuilding Corp., Hog Island
- SIPLEY, LOUIS W., Rate Estimator, Midvale Steel & Ord. Co., Philadelphia
- SLICER, HARRY T., Assistant to Superintendent, Tyler Tube & Pipe Co., Washington
- STINSON, JOHN A., Production Engineer, Midvale Steel & Ordnance Co., Philadelphia

Texas
- SCOTT, FLOYD L., Engineer, Hughes Tool Co., Houston

Virginia
- DOHERTY, CHARLES H., Jr., Assistant Testing Engineer, E. I. du Pont de Nemours & Co., Hopewell

Cuba
- MURRAY, HAROLD B., Engineer, Sales Department, United States & Cuban Allied Works Eng. Corp., Havana

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

Alabama
- CAINE, WILLIAM P., Steam Engineer, Ensley Wks., Tennessee Coal, Iron & R. R. Co., Ensley

Illinois
- WILSON, JOSEPH B., Commercial Engineer, Westinghouse Electric & Mfg. Co., Chicago

PROMOTION FROM ASSOCIATE-MEMBER

Massachusetts
- OLSON, MARTIN L., Instructor (Junior Master), Hyde Park High School, Boston

Ohio
- HUNTER, SAMUEL R., Superintendent of Production, American Rolling Mill Co., Middletown

Washington
- HAYS, LEWIS T., Tramway Engineer, U. S. Steel Products Co., Pacific Coast Dept., Seattle

PROMOTION FROM JUNIOR

Colorado
- BISSELL, ALBERT W., Assistant Superintendent, Wire Mill, Colorado Fuel & Iron Co., Pueblo

Illinois
- WACHS, THEODORE, Engineer, The E. H. Wachs Co., Chicago

Michigan
- LANNING, JOHN G., Assistant to Vice-Pres., Detroit Lubricator Co., Detroit

Pennsylvania
- BRAYTON, HAROLD M., Artillery Ammunition Designer, Frankford Arsenal, Philadelphia
- GRAF, JOHN C., Material Agent, Southwark Foundry & Mch. Co., Philadelphia
- ROSENCRANTS, FAY H., Purchasing Assistant, Emergency Fleet Corp., Philadelphia

Wisconsin
- ALLISON, LAWRENCE M., Chief Engineer, Lawson Aircraft Co., Green Bay

REINSTATEMENT AND PROMOTION FROM JUNIOR

Georgia
- McKEE, JOHN F., Engineer and Draftsman, General Fire Extinguisher Co., Atlanta

New York
- PENDLETON, FRANK E., Chief Engineer, New York Steam Co., New York

Ohio
- HORTON, WILLIAM M., Jr., General Superintendent, The Adams-Bagnall Elec. Co., Cleveland

Pennsylvania
- MORRISON, EGBERT R., Estimating Engineer, Union Spring & Mfg. Co., Sharon

South Carolina
- BARKLEY, MATTHEW B., Vice-President, Cameron & Barkley, Charleston

Wisconsin
- KEOGH, JERE K., Erecting Engineer, Allis-Chalmers Mfg. Co., Milwaukee

SUMMARY

New applications	253
Applications for change of grading:	
Promotion from Associate	1
Promotion from Associate-Member	3
Promotion from Junior	7
Reinstatement and Promotion from Junior	5
Total	269

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

Members applying in person for Government positions at such places as Navy Yards should invariably make appointments before hand by letter, telephone or telegraph, and arrange to have passes or the equivalents so that they can gain entrance. In this way they will avoid disappointment.

YOUNG MEN wanted for the Department of Military Aeronautics. Should have mechanical training and, if possible, be thoroughly grounded in electrical work. May be of draft age and will go as enlisted men, then assigned to Training School for Radio Mechanics and after instruction will be sent overseas. They will be inducted at once.

TECHNICAL MAN or one with several years' experience to act as assistant engineer of tests. Salary, $4 a day. 2625.

TECHNICAL MEN for the Navy with considerable engineering experience in large power plants, preferably married. Men who have been superintendents of repair plants desired. Not over 35 years of age. 2629.

MECHANICAL ENGINEERS especially experienced in machine-shop practice to act as chief inspectors for the Ordnance Department on shell machinery and automatic screw-machine work. 2633 A.

EXPERIENCED MEN also wanted on steel and forging work. 2633 B.

Men for above to be over draft age. Salaries for satisfactory men with considerable training from $2400 to $3000 per annum.

MECHANICAL ENGINEERS, experienced in ship construction to act as assistants. Salary, $2400 per annum. 2637

TECHNICAL MAN capable of making reports for technical journal. One with editorial experience necessary. Knowledge of wood desirable although not absolutely necessary. Maximum salary, $3500. 2640.

ASSISTANT in charge of research and development. Man to bring to stage of commercial production parts made of sheet metal, fabrics, rubber and die casting. Applicants must have personality to secure coöperation of manufacturers in development work along above lines. Salary, $3600 per annum. 2642.

PRODUCTION ENGINEER as superintendent of plant, or one who has had an execu-

tive position in manufacturing concern. Knowledge of rubber desirable but not essential. Man occupying this position would probably be commissioned. 2644.

CIVILIAN POSITIONS

MASTER MECHANIC, young, energetic, good tool designer and familiar with precision work and production methods. Man who has had experience with automatic and with precision grinding. Location Connecticut. 0445-H.

MECHANICAL LABORATORY ASSISTANTS AND DRAFTSMEN required for important war work in development of parts for sheet metal, fabric and rubber. Graduates from manual training schools with one or two years' shop experience or one or two years in an engineering school desirable. Enclose photograph, stage age, give references, position in draft and willingness to enlist or be inducted in the army for work of this nature. 0459-H.

SPLENDID OPPORTUNITY in an old-established business for practical man with combination of mechanical and business ability who understands sheet-metal and light-screw machine work; one who can also develop sheet-metal specialties to be marketed so as to afford volume production to the factory. Location New York. 0460-H.

ASSISTANT CHIEF ENGINEER to act as chief engineer during temporary absence of the latter. Work is in nature of quantity-production war work of the highest importance; in factory employing 2600, and large number of draftsmen; commands excellent salary. Location Brooklyn, N. Y. 0461-H.

ASSISTANT PROFESSOR OF EXPERIMENTAL ENGINEERING in an Eastern University; to have charge of classes for juniors and seniors in the steam laboratory and materials testing department and to give a course in kinematics to sophomores. Salary about $1500, depending upon previous experience. 0462-H.

TECHNICAL GRADUATE, mechanical engineer, preferably with one or two years' experienee for power-plant lay-out and steam work. Salary $25 a week to start. Location New York State. 0463-H.

MECHANICAL ENGINEER with experience in design, testing and general engineering work in connection with small and medium steam turbines and their applications. Reduction-gear experience also desirable. Must have good business and executive ability and be able to handle a variety of work in connection with steam turbines and turbine-driven machines. Give full details of training, experience, salary expected and photograph. Location Connecticut. 0464-H.

DRAFTSMAN, power-plant equipment. Salary, $125. Location New York. 0466-H.

DRAFTSMAN on industrial and chemical plants. Salary, $150. 0467-H.

MECHANICAL ENGINEER with machine shop experience for position similar to master mechanic. Salary $50 to start. Location Brooklyn. 0468-H.

PROFESSOR OF MECHANICAL ENGINEERING in charge of department; should be technical graduate with both teaching and practical experience. Send full statement of training and experience, references and a late photograph. Salary $2400 for ten months. Location Idaho. 0471-H.

PROFESSOR OF ELECTRICAL ENGINEERING during period of war. Technical graduate preferably with teaching and practical experience. Send full statement of training and experience, references and a late photograph. Salary $2400 for ten months. Location Idaho. 0472-H.

INSTRUCTOR IN APPLIED SCIENCE LABORATORY, INSTRUCTOR IN ELEMENTARY APPLIED ELECRICITY AND MECHANICS for technical school in Greater New York. Preference given to men with mechanical or electrical technical training, with practical and teaching experience. Position permanent. Give full personal and experience data and photograph. State salary expected. 0473-H.

TECHNICAL TRAINED MECHANICAL ENGINEER, experienced in power-plant design, testing and operation. Location Connecticut. 0474-H.

MECHANICAL ENGINEER AND DESIGNER with extensive experience in design and construction of shipbuilding cranes, derricks, drag-line excavators and similar work. High-grade man wanted to take charge. Location Pennsylvania. 0475-H.

INSTRUCTOR in mechanics, mechanical drawing, mathematics, etc., for railroad-shop apprentices. Preferably a college graduate with some knowledge of railroad equipment and shop machinery. Salary $200. Location Texas. 0476-H.

INDUSTRIAL ENGINEERING PRODUCTION PROBLEMS. Opportunity for a man qualified by education to undertake work of this nature in large steel-castings plant. Preference given to man who has served apprenticeship in railroad shops. Location Ohio. 0477-H.

EXPERIENCED TOOL AND FIXTURE DESIGNER, with experience in the design of large machine tools. Essential industry. Location Central Ohio. 0478-H.

TIME-STUDY ENGINEER with shop-practice experience, draft exempt; time-study experience on automatic machinery desirable. Must have personality, diplomacy and tactfulness. Young man if possible. Salary $40 per week. Location New Jersey. 0479-H.

DRAFTSMAN with experience in the design of small engines. High-grade man. Salary $175 to $225. Location Pennsylvania. 0481-H.

DRAFTSMAN with experience on boiler design. High-grade man. Salary $175 to $225. Location Pennsylvania. 0482-H.

DRAFTSMAN with experience on locomotive-crane design. High-grade man. Salary $175 to $225. Location Pennsylvania. 0483-H.

DRAFTSMAN with experience on the design of steel towboats and barges. High-grade man. Salary $175 to $225. Location Pennsylvania. 0484-H.

DESIGNING DRAFTSMAN, acquainted with designing heavy machinery such as brass and copper rolling mills, hydraulic-press work, etc. Good designer and not an ordinary draftsman. Will make any reasonable inducement to the right man. Location Connecticut. 0485-H.

SALESMAN for special machinery. With technical training and also accustomed to meeting the engineering staffs of large organizations. Location Ohio. 0488-H.

YOUNG ORGANIZATION ENGINEERS, possessing both analytical and executive ability for time and motion-study work to standardize operations; large rubber plant. Large and expanding field for able men. Location Ohio. 0489-H.

PRODUCTION ENGINEER in newly organized planning department of large ice-making machinery plant. Location New Jersey. 0490-H.

MECHANICAL ENGINEER with sufficient experience to handle any design work in connection with the standardization of apparatus or its modification to meet specific requirements. Man with practical shop experience and technical training preferred. Will be subordinatae to engineer in charge of design and will have supervision over several assistants. Maximum initial salary $2400 a year, depending on the applicant's qualifications, etc. Location Brooklyn, N. Y. 0491-H.

ASSISTANT for checking all drawings against standards; accurate in work. Man with previous experience in this capacity preferred. Shop experience and technical training valuable assets but not required. Maximum initial salary about $35 per week. Location Brooklyn, N. Y. 0492-H.

SALESMAN, familiar with the steam-specialty business of the New York District. Position has every prospect of permanency and advancement. 0495-H.

SEVERAL FIRST-CLASS DRAFTSMEN with broad engineering experience wanted immediately. Good future for right man. Location Ohio. 0496-H.

THREE ENGINEERS, experienced in substituting mechanical equipment for hand labor. Must be familiar with all kinds of conveying equipment. Good future for right men. Location Ohio. 0497-H.

ASSISTANT MECHANICAL ENGINEER, familiar with general machinery in machine-shop and mill engineering. Must be competent to lay out and direct installation of new machinery, direct repairs and alterations on present equipment. Concern manufacturing mechanical rubber goods and employing about 2000. Technical graduate preferred. Salary $1500 to $2000, depending on man. Location Massachusetts. 0498-H.

MECHANICAL ENGINEER for production of airplanes; out of draft age or in Class 4. Salary $175. Location New York. 0499-H.

ASSISTANT PROFESSOR IN MECHANICAL ENGINEERING. Location Pennsylvania. Salary $1800. 0500-H.

ASSISTANT MECHANICAL ENGINEER with practical and theoretical experience and training in tool engineering; familiar with methods of manufacture for small, interchangeable parts. War work. Splendid opportunity for young man who can think and possesses unusual initiative. Location Brooklyn, N. Y. 0501-H.

MECHANICAL ENGINEERS AND DRAFTSMEN for designing machinery wanted by large and long-established company, located near New York City. 0502-H.

TURBINE DESIGNER of experience, capable of taking complete charge of design and construction of turbines and reduction gears, wanted by large and long established company, located near New York City. 0503-H.

TRAINED MECHANICAL ENGINEER with inventive ability to develop apparatus under the direction of chief engineer. Must have thorough grounding in theory of physics and mechanics. Only capable men of genuine ability will be considered. Give full details of training and experience. Location New York City. 0504-H.

YOUNG MAN WITH TECHNICAL EDUCATION and preferably some subsequent experience, for a steam-turbine manufacturer

mainly engaged in war work. State experience, draft classification, salary expected. Location Connecticut. 0505 H.

PRODUCTION ENGINEER, familiar with up-to-date production methods, particularly munitions production, heavy steel castings, etc. Salary about $6000 to $7000 a year. 0506 H.

INDUSTRIAL STATISTICIAN for Government work. High-grade man with salary in proportion to past records of results obtained. Man of draft age considered and if appointed would possibly be inducted into the Service. 0507 H.

MASTER MECHANIC to take charge of boilers, pumps, machinery and motors. Location New York. 0510 H.

MEN WITH TECHNICAL TRAINING or experience wanted for testing and efficiency work in power plants and substations of large electric-railway system. Good pay for men of adequate qualifications in the field of electric or steam-plant equipment. Give status with respect to draft. Location Brooklyn. 0511-G.

DRAFTSMEN, DESIGNERS, experienced in calculating and automatic machinery, typewriters, etc. Permanent positions to competent men. Location New York City. 0512 G.

PLANT ENGINEER of extensive and exceptional experience in plant engineering work, maintenance department, familiar with entire plant equipment, tools, jigs, die work, building construction, plant layout. Man of about 35 to 40 years of age. Location Philadelphia. 0514-G.

TEACHER for production work in connection with our coöperative courses in engineering; a man with actual experience in production and sufficiently broad experience to cover rather wide field. Salary $2400 or $3000 for three months' service. Location Ohio. 0515 G.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be on hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MECHANICAL ENGINEER, age 32, associate member, now employed as chief engineer of a plant making sugar, evaporating and heavy machinery. Experience of eight years in designing, estimating, purchasing and practical manufacture incidental to this class of machinery. H-207.

PRODUCTION OR WORKS MANAGER with specific training in all branches of shop, time-study and piece-rate efficiency and system, cost and general accounting, production and works management in metal stampings and fittings, tubing, general machine-shop and foundry-forging and die work, engine and general assembly. Available at short notice. Salary approximately $10,000. H-208.

EXECUTIVE OR PRODUCTION ENGINEER. Graduate mechanical engineer, 35 years of age, with 12 years' experience as an executive and in scientific management installations desires connection with manufacturing concern offering an attractive future as reward for hard work and results. At present employed. H-209.

PRODUCTION AND ENGINEERING EXECUTIVE with wide experience in the manufacture of interchangeable parts. Available September 15. Married, aged 30. In class IV of the draft. H-210.

MECHANICAL ENGINEER of executive ability, at present holding position but having little work to do; prefers to be busy. American, past draft age, married, technical education and 15 years' experience in industrial and power-plant work. H-211.

MECHANICAL AND MARINE ENGINEER, member, desires position of high responsibility, having upward of 18 years' experience in designing and operating large power plants and large ocean-going vessels. Will prove an expert on combustion and thermodynamics of either plant or ship. Will go where wanted. H-212.

FACTORY MANAGER OR ASSISTANT FACTORY MANAGER, with 30 years' practical experience and wide knowledge of mechanics in general. Twelve years in last position. Can furnish best of references. Well-informed on gas-engine work and also Liberty motor, with fair knowledge of heat-treating alloy steels. Readily adaptable to shop conditions. H-213.

WORKS MANAGER OR SUPERINTENDENT for manufacture of interchangeable parts. Experienced with large organizations and modern methods of operation. Graduate engineer with practical training in design, installation, operation and business administration. H-214.

MECHANICAL ENGINEER, college graduate, exempted from draft, experienced in sugar machinery and steam-power plant throughout Hayti, Santo Domingo, and Porto Rico, will consider a proposition to go to Cuba or Honolulu for the coming crop. H-200.

MASTER MECHANIC OR MAINTENANCE ENGINEER, member, now employed. Thorough technical and practical experience covering the construction, maintenance and operation of industrial works, steam- and water-power plants. Steam and fuel economy a specialty. Available about September 1. H-201.

MECHANICAL ENGINEER, member, thoroughly experienced in general mechanical and structural engineering; now in charge of engineering work on contracts aggregating twenty million dollars. Good organizer, executive ability, exemplary habits. Thirty-nine years of age. Will consider engineering sales proposition. Middle West preferred. Salary $5,000. H-202.

MECHANICAL OR WORKS ENGINEER, age 31, married, technical graduate, eight years' experience in design, construction and maintenance of paper mills and metal-manufacturing plants. Good organizer and executive. H-203.

SUPERINTENDENT OR MECHANICAL ENGINEER for cement plant, glasswork, porcelain or chemical works. Technical graduate, 39 years of age, married, 14 years' experience, able to handle tactfully executives and men; familiar with design, erecting and operating of crushers, dryers, kilns, furnaces, lehrs and grinding and labor-saving machinery. Can introduce methods of chemical control of raw material and finished product. Employed, but desires responsible position in a northern state. H-204.

SALES ENGINEER of high-grade experience desires a position as sales manager, sales engineer or plant manager; energetic salesman. Has travelled extensively and is well acquainted with machine and automobile manufacturers. Graduate mechanical engineer and good executive. H-205.

JUNIOR ENGINEER desires engineering or executive work with company situated in New York City. Mechanical engineering graduate of Worcester Polytechnic Institute, experienced in office executive work, good correspondent, and clear, rapid thinker, able to adjust himself quickly to new conditions. Is at present holding a civil service position in appraisal-engineering work. Married, exempt from draft, 25 years old and a junior member of the A.S.M.E. and S.A.E. H-206.

SALESMAN OR PURCHASING AGENT well versed in modern sales methods and systems, accustomed to meeting principals of large organizations, and estimating requirements to meet conditions. Has travelled extensively, thoroughly competent to complete contracts. Open for engagements after August 1. H-209.

MECHANICAL ELECTRICAL ENGINEER. 12 years' broad experience, technical training. Tactful executive, strong on coöperation, standardization and resource. Age 32, married. Specialty is design, development and production of small electrical equipment and other accessories with investigation of field for demand and requirements. Fully acquainted with modern factory methods and drawing office management, tool room and die work and finish processes. H-215.

ASSISTANT TO CONSULTING ENGINEER. Junior member, 1913 technical graduate, five years' practical experience in operating, testing and drafting in both electrical and mechanical engineering, four years with one concern, one year of power-plant drafting and heating and ventilating. Age 29, married, in Class IV, employed at present. Wishes a responsible position on the Pacific Coast. Salary, $150 per month. H-216.

FACTORY EXECUTIVE, experienced efficiency and mechanical engineer, in foundry practice, cotton and woolen textile machinery, machine tools, jigs and fixtures, oil mill, hydraulic, transmissions and wood-working machinery, is open for stable proposition offering adequate salary and ample authority. 35 years old. H-217.

CHIEF ENGINEER OR MASTER MECHANIC with thorough technical and practical experience covering construction, operation and upkeep of steel plant, specialty metallurgical work, heating and melting furnaces. H-218.

COMBUSTION ENGINEER, a graduate mechanical engineer, with 13 years' experience in the combustion of anthracite and bituminous coal, hand and stoker fired. Well trained in fuel-research work, sampling and the analysis of fuel. Capable of taking charge of the complete problems of a company consuming a large tonnage. H-219.

WORKS MANAGER, associate member, successful executive, experienced in design, purchase of materials and manufacture of general steel-plate work and allied lines, at present in complete charge of works employing 200 men, desires connection with a firm offering greater opportunities. H-220.

GENERAL MANAGER OR ASSISTANT TO PRESIDENT of a manufacturing company, desired by a resourceful and successful executive mechanical engineer in factory layouts, equipment and management. Complete record on request. H-221.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

News of Other Societies

American Institute of Electrical Engineers

THE thirty-fourth annual convention of the American Institute of Electrical Engineers was held in Atlantic City, June 26 to 28. On Wednesday morning, the opening day, President E. W. Rice, Jr., delivered the annual address, taking as his subject, A Review of Electrical Engineering Progress. He called special attention to the work of engineers in connection with the war, and to the continued efforts which will be needed to carry on the processes of reconstruction after the war. After the close of his address he introduced President-Elect Prof. C. A. Adams, who responded briefly, touching upon the period of reconstruction which is bound to take place at the close of the war, and suggesting the possible need of altering or extending the scope of the activities of the Institute to the service which it can render to the nation and the world.

An important feature of the convention was the conference of Institute officers and delegates of sections and branches each convention day at luncheon, from 12.30 to 2.30 p. m. About fifty officers and delegates of sections met at these conferences.

On Wednesday afternoon, at the first technical session, the papers read dealt with various phases of transmission problems. The Thursday morning session was devoted to several papers on the general subject of protective devices. The papers were as follows: Lightning Arrester Spark Gaps—Their Relation to the Problem of Protecting Against Impulse Voltages, by C. T. Allcutt, of the Westinghouse Electric & Mfg. Co.; The Oxide Film Lightning Arrester, by C. P. Steinmetz, of the General Electric Co.; The Oxide Film Lightning Arrester, by Crosby Field, Ordnance Department, U. S. A.; and Design of Transpositions for Parallel Telephone and Power Circuits, by H. S. Osborne, of the American Telephone & Telegraph Co. Charles E. Stuart of the Power and Light Division of the United States Fuel Administration also outlined the plans which have been formulated by the Government to take care of the question of fuel supply and fuel requirements in order to conserve fuel necessary for the essential industries and for heating purposes.

On Thursday evening a highly interesting war session was held, opened by an address on Engineers and the War, by General William M. Black, Chief of Engineers of the United States Army. General Black gave a most vivid description of the work of the engineers in France, and exhibited several reels of moving pictures showing not only much of their detailed routine work, but also the enormous engineering construction works which have been erected at some of the French ports of debarkation. The balance of the session was devoted to papers on Electric Power for Nitrogen Fixation, by E. Kilburn Scott, Consulting Engineer, of London, and America's Power Supply, by C. P. Steinmetz.

Technical sessions were held Friday morning and afternoon, at which papers on miscellaneous subjects were presented in the field of electrical engineering. One of these of general interest to the engineer was on The Automatic Hydroelectric Plant, by J. M. Drabelle, of the Iowa Railway & Light Co., Cedar Rapids, Ia., and L. B. Bonnett, of the General Electric Co., Schenectady, N. Y.

American Society of Heating and Ventilating Engineers

The semi-annual meeting of the American Society of Heating and Ventilating Engineers was held at Buffalo, June 26-28. The rules for limiting the supply of coal to domestic consumers next winter were advanced to their final stages, and will now be submitted to the Bureau of Mines and to the Fuel Administration. Further progress was made in the society's plans to raise funds for the maintenance of a research bureau. Prof. J. E. Emswiler, of Ann Arbor, Mich., presented details of the methods used at the University of Michigan for testing radiators by electrical means, using an electric heater to generate the steam consumed by the radiator and determining the heat required by measurement of the energy consumed in the heater. Thomas Chester, engineer for the American Blower Company, reviewed the development of mine ventilation in this country. The amount of air used to ventilate a coal mine is usually from two to three times the weight of the coal mined, and the required volume is computed by allowing 150 to 200 cu. ft. per min. per man and 500 cu. ft. per min. per animal. He stated that from 10 to 30 per cent more coal can be mined in a thoroughly ventilated mine.

A session on drying was opened with a paper by W. A. Perry, who pointed out that the big problem of the Food Administration is not that of prices, but the distribution of the available food supply. H. C. Gore, chemist with the Department of Agriculture, described the recent progress made in the drying of vegetables, and referred to some of the principal advantages derived from this process: in the case of tomatoes the saving of freight amounts to 99 per cent; there is also an enormous saving of space. The department has developed a type of drier known as the *general purpose* dryer. Nathan Ovitz, of the J. P. Devine Co., spoke on the possibilities of the vacuum process in drying vegetables and fruits. While the initial cost of the apparatus is higher, the operating cost is low, and all danger of burning the product is eliminated. W. L. Fleisher explained his idea of using the heating and ventilating equipments in public-school buildings throughout the country for the drying of foodstuffs.

The afternoon session on Thursday was convened at the Buffalo Canoe Club, Abino Bay, where dinner was served later. In the first paper, Reasons for Failures of Heating Systems, J. D. Hoffman enumerated the conditions of poor building construction met by heating engineers and the restrictions placed on their work by the owners of houses who insist upon uneconomical installations of piping systems. In the paper next following, A Campaign for Fuel Economy in House Heating, C. W. Baker, recommended warm-air furnace heating, and urged the addition of an auxiliary cold-air duct by which the air supply to the furnace may be taken from inside the house, instead of from outdoors, during very cold or windy weather. Konrad Meier discussed Economy in Heating, basing his ob-

servations on his experience in Switzerland, where he is located. War regulations provide in that country that rooms should not be heated over 60.8 deg. fahr., and the heating of halls and stairways is stopped altogether. He favored intermittent heating by steam, and suggested the wider use of coke as a fuel in place of anthracite. In the final paper on Reforms in the Design of Hot-Air Heating Plants Needed to Compete with Other Systems, C. W. Baker presented the reasons why, by the use of intelligent methods in the design of a hot-air furnace plant, it can be made not merely the equal, but the superior, of either steam or hot-water heating for all buildings of moderate size.

At the closing professional session, on Friday morning, W. M. Franklin's notes on Spontaneous Combustion gave an exhaustive treatment of the principles of combustion, and indicated the two principal methods of preventing spontaneous combustion: either by enclosing the susceptible material in airtight, fireproof cans, or by spreading it in a thin layer freely exposed to the air. A Bulletin of the Bureau of Mines containing Notes on Spontaneous Combustion of Coal was read before the convention. The heating of the base hospital at Camp Dodge was also described in a paper by P. M. O'Connell. (Based on the report in *The Heating and Ventilating Magazine*, July 1918, pp. 27-42)

American Boiler Manufacturers' Association

The thirtieth annual convention of the American Boiler Manufacturers' Association was held on June 17 and 18 at Philadelphia, with M. H. Broderick, president of the association, in the chair. The association and guests were welcomed to Philadelphia on behalf of the mayor and citizens by Dr. E. J. Cattell, city statistician. Following Dr. Cattell's address, William H. Burr, president of the National Founders' Association, discussed informally the present industrial conditions and their relation to war work. D. M. Metcalf, chief inspector of steam boilers, Toronto, Ontario, described industrial conditions in Canada, especially as relating to shell making, shipbuilding and aeroplane building. Dr. D. S. Jacobus, of the Babcock and Wilcox Company, Mem.Am.Soc.M.E. Boiler Code Committee, treated at length the question of boiler-furnace design.

The work of the American Uniform Boiler Law Society in promoting the adoption of the A.S.M.E. Boiler Code was outlined by Charles E. Gorton, chairman of the American Uniform Boiler Law Society.

C. O. Meyer, deputy inspector of the State of Ohio, presented a communication from his department, pointing out that the A.S.M.E. Code does not include vertical-flue boilers and track locomotive boilers, and that as a consequence it had been necessary to make special rules for the former and use the rules of the Interstate Commerce Commission for the latter. He intimated that if such features were not covered by the Boiler Code Committee, Ohio might find it necessary to return to its own rules that were in force before the adoption of the A.S.M.E. Code, and he suggested that the chairman of the American Uniform Boiler Law Society should be a man who is neither a member of the A.S.M.E. Code Committee nor a boiler manufacturer.

A letter from the United States Board of Supervising Inspectors pointed out that their own inspection rules had been in use for sixty years, had met all conditions, were efficient and safe, and for those reasons the board declined to adopt the A.S.M.E. Code instead.

Charles M. Schwab, Director-General of the United States Shipping Board Emergency Fleet Corporation, declared that the situation regarding marine engines and boilers was critical; he said 80 or 90 hulls were already in the water awaiting power equipment. To meet the emergency, all manufacturers of boilers, engines and other ship equipment and accessories are being urged to increase their capacity as much as possible and make extensions wherever needed, with Government funds, which will be available for this purpose.

W. C. Connelly, of the D. Connelly Boiler Company, Cleveland, Ohio, was elected president for the coming year. (*The Boiler Maker*, vol. 17, no. 7, July 1918, pp. 190-197)

American Society for Testing Materials

The American Society for Testing Materials held its twenty-first annual meeting at Atlantic City, N. J., June 25 to 28. It was evident that there is an increased interest in specifications due to the great expansion in this field for war purposes.

The sulphur and phosphorus question in steel specifications was the only one that caused any difference of opinion, but a satisfactory solution was arrived at by the adoption of the following amending clause:

> In view of the abnormal difficulty in obtaining materials in war time, the rejection limits for sulphur in all steels and for phosphorus in acid steels shall be raised 0.01 per cent above the values given in the specifications. This shall be effective during the war and until otherwise ordered by the society.

This clause is to be printed under the title of each specification containing chemical requirements *except* those for boiler and firebox steel and those for boiler rivets. Further, as regards sulphur the note shall not apply to the specifications for carbon-steel car and tender axles.

Urgent war conditions led to preparing the single new specification, for cast-steel anchor chain. A threatened shortage in wrought chain led to active study in several iron works of the possibilities of cast chain, and highly successful results were obtained. The steel committee made tests of the new material and drafted specifications to govern its acceptance, which were accepted by the society as tentative. The steel for chain use, according to these specifications, is to be made in the electric furnace and produced in dry-sand molds or cores.

R. J. Wig, chief engineer, concrete ship division, Emergency Fleet Corporation, delivered an address on the concrete ship. He reviewed the progress of this industry and indicated that its permanency was assured. An interesting statement was that if the wooden ship is taken as 100, the relative weights of the concrete and steel ships are respectively 90 and 75. He felt assured that a cement has been developed recently whereby a lighter ship can be constructed, probably bringing down the ratio from 90 to 77 or 80 as compared with the steel ship at 75.

Dr. Henry M. Howe introduced a topical discussion on industrial research, and emphasized the vital importance of this subject to the nation's present and future welfare.

During the meeting the sad news was received of the death of the distinguished secretary of the society, Dr. Edgar Marburg, an account of whose life is given elsewhere in this number.

American Concrete Institute

The annual meeting of the American Concrete Institute, which was postponed from its regular time in February because of rail congestion, was held on June 27 to 29, at Atlantic City, N. J., simultaneously with the meeting of the American Society for Testing Materials.

Advantage was taken of this concurrence in providing for

joint meeting of the two societies, at which papers dealing with concrete were presented alternately by members of the two bodies.

One of the sessions was devoted to the subject of concrete ships and was illustrated by a number of moving pictures, showing among other things some of the operations in one of the United States Government concrete ship yards. The leading paper of this session was entitled Principles of Design of Concrete Ships, by R. J. Wig, chief engineer of the department of concrete ships, and S. C. Hollister, engineer of design. It was an excellent exposition of the details required in the design of ships, particularly of concrete ships, and outlined the study that the concrete ship department has made on the subject.

Another session was devoted entirely to the subject of concrete houses, and consisted of the presentation by the different members of the Committee on Industrial Concrete Housing of various papers taking up the several divisions of the housing problem. Lieut. K. H. Talbot gave full and valuable information on the different kinds of forms, methods of placing concrete and methods of finishing.

Papers on concrete tests were read at other sessions. J. L. Pearson, of the United States Bureau of Standards, gave in some detail the present status of the stucco tests being conducted by the Bureau.

The papers on design and construction included a complete analysis of a reinforced-concrete chimney by J. C. Mingle, a discussion of the stresses in eccentrically loaded reinforced columns by L. J. Mensch, and an analysis of the treatment of concrete surfaces by J. J. Earley, Washington, D. C.

Several important reports from different committees were submitted to the convention, as well as papers on the details of certain concrete structures.

Prof. W. K. Hatt, Purdue University, Lafayette, Ind., was reëlected president for the ensuing year. (From report in *Engineering News-Record*, July 4, 1918)

National Electric Light Association

The thirty-fourth annual meeting of the National Electric Light Association was held at Atlantic City, N. J., June 13-14.

President John W. Lieb, general manager and vice-president, New York Edison Co., in his address to the Association, pleaded for the continuation of teamplay in the electrical industries, in which he included street railways, telephone, telegraph, light, power and the manufacturing enterprises. He regarded the "linking up" of systems to further fuel economy as the most important problem now confronting the industry.

Samuel Insull, president, Commonwealth Edison Co., Chicago, suggested that relief from the burdens of high cost of conducting the industry could be had by applying for rate increases to the public-utility commissions. He urged that central stations drop extravagances of a capital character and of an operating nature.

P. B. Noyes, Director Conservation Division of the United States Fuel Administration, pointed out the work the administration was doing. America must mine 220 million tons of coal in excess of that ever before mined in one year, and the draft has taken away 35,000 coal miners. He stated that it was impracticable completely to cut off fuel to non-war industries. One ton of coal meant keeping at least fifty people at work. The Administration expects the utilities to do much of their own policing in respect to the economical use of fuel.

Dr. S. S. Wheeler made an address on training the blind to do work in the electrical industry. They are now successfully winding coils of stators and armatures at the same piecework rate paid sighted persons.

Charles E. Stuart, Chief of Power and Light Division, United States Fuel Administration, in his paper on War Conservation of Power and Light detailed the manner in which the Power and Light Division will carry out the general plans laid out for the conservation of light and power by the Bureau of Conservation of the United States Fuel Administration. Isolated plants will be eliminated. Shop committees appointed by the management of manufacturing and industrial establishments will have charge of all details in the operation of their plants that would in any way contribute to economy in fuel. Interconnection of the power systems of the country will permit the utilization of considerable excess waterpower which is at present available. In coöperation with the Joint Commission on Refrigeration, the Power and Light Division is planning to introduce a number of proved economies in the operation of ice and refrigerating plants.

W. W. Nichols, of the Allis-Chalmers Co., read a paper on The Development of Water Power as a War Measure. The 1,058,000 hp. of hydroelectric machinery built and installed in 1917 represented a saving of 8,500,000 tons of coal. Ten per cent of the estimated coal shortage of this year would be met if the industry could repeat that performance.

W. F. Wells, vice-president and general manager of the Edison Electric Illuminating Co., Brooklyn, N. Y., was elected president of the association. (Based on the report given in *Power*, June 25, 1918)

Society for the Promotion of Engineering Education

The twenty-sixth annual meeting of the Society for the Promotion of Engineering Education was held at Northwestern University, Evanston, Ill., June 26 to 29, with an attendance of 125 representing 40 institutions. The subject for discussion was Engineering Education and the War.

The War Department was represented by Drs. J. R. Angell, C. R. Mann and S. P. Capen. Dr. Angell spoke at length on the Committee on Education and Dr. Mann presented the final report of the Joint Committee on Engineering Education which was organized at the Cleveland meeting in 1907.

One of the most important subjects discussed was the question of attendance at engineering schools next year. Announcement was made of the modification of the Selective Service Regulations as follows:

> Under such regulations as the Secretary of War may prescribe, a registrant who is regularly enrolled in a school approved by the War Department Committee on Education and Special Training, and is pursuing full-time courses leading to a bachelor or higher degree in medicine, engineering, physics, chemistry, and other technical subjects essential to the prosecution of the war, or who is an indispensable teacher in such courses, or who is engaged in the training of Army personnel, may enlist in the Enlisted Reserve Corps, and thereafter on presentation by the registrant to his local board of his certificate of enlistment, such certificate shall be filed with his questionnaire, and the registrant shall be placed in Class 5 on the ground that he is in the military service of the United States.

Dr. Capen read a paper on the Relation of the Bureau to the War and to Engineering Schools. The report of the standing committees occupied practically one day. The Committee on Mathematics recommended that the society, through its executive officers, request the coöperation of the Mathematical Association of America toward the appointment of a joint committee for consideration of the entire question of teaching of mathematics.

The joint session of the Western Society of Engineers, the Chicago Section, A. S. M. E., the Chicago Section, A. I. E. E., and the S. P. E. E. on Thursday night, was a success in every way. A. S. Baldwin, chief engineer, Illinois Central Railroad, presided.

The society celebrated its 25th anniversary at this meeting. The following men were present who were at the organization of the society at the World's Fair in 1893: G. C. Anthony, Ira O. Baker, L. M. Hoskins, William T. Magruder, and S. N. Williams. They were called upon for addresses at the get-together meeting in the gymnasium on Wednesday night.

The institutional delegates sent the following telegram to the Secretary of War:

> The institutional delegates present at the convention of the Society for the Promotion of Engineering Education express their hearty appreciation of the cordial relations which have existed between the engineering schools and the Committee on Education and Special Training of the War Department and offer their sincere coöperation in support of plans for the Student Army Training Corps.

The presidential address, Essentials in Engineering Education, was read by Vice-President John F. Hayford in the absence of President Milo S. Ketchum.

Committee on Development of the American Society of Civil Engineers

The spirit of the times for high ideals and greater service as now evidenced in all walks of life and business is reflected in resolutions adopted by the Board of Direction of the American Society of Civil Engineers, on June 18, 1918. The same spirit was shown in the discussion on the objects of an engineering society as the result of Mr. Cooke's paper on The Public Interest as the Bed Rock of Professional Practice, at our Spring Meeting at Worcester; and it is further attested in the principles enunciated by the Engineers' Club of Dayton, to which reference is made in another column of this issue. The significance of this spirit is indicated in the preamble preceding the resolutions relating to the American Society of Civil Engineers, the text of which follows:

> The development and application of the sciences in recent decades have caused profound changes in the social and industrial relationships of all peoples.
>
> The engineer has been a leader in this progress.
>
> Sociological and economic conditions are in a state of flux and are leading to new alignments of the elements of society.
>
> These new conditions are affecting deeply the profession of engineering in its services to society, in its varied relationships to communities and nations, and in its internal organization.
>
> A broad survey of the functions and purposes of the American Society of Civil Engineers is needed in order that an intelligent and effective readjustment may be accomplished so that the Society may take its proper place in the larger sphere of influence and usefulness now opening to the profession.
>
> Such a survey and readjustment can be accomplished successfully only with the aid of the membership throughout the country.
>
> Any steps toward changes in organization must lead to a revision of the Constitution of the Society, which has not been materially modified for many years, during which the Society has grown rapidly and has established 22 Local Associations of Members.
>
> The Constitution should be revised only after securing the views of the membership of the Society as to what its purposes and activities should be and as to the instrumentalities through which these purposes and activities should be carried out.
>
> Any changes in organization must take into account all the conditions above indicated, and also the relationship of the American Society of Civil Engineers to other engineering organizations and to the public.
>
> Therefore:
>
> *Resolved*, That a committee be created to report on the purposes, field of work, scope of activity and usefulness, organization, and methods of work of the American Society of Civil Engineers, and to make recommendations concerning these matters; the committee to consist of one member chosen by each Local Association of Members, and seven members at large appointed by the President.
>
> *Resolved*, That the President be instructed to select from this committee an executive committee of not less than five nor more than nine members and to appoint the chairman of this executive committee, who shall also be the chairman of the general committee.
>
> *Resolved*, That the President be instructed to prepare a precept for the general guidance of this committee.
>
> *Resolved*, That this committee be requested to present to the Board of Direction a preliminary report, not later than November 1, 1918, so that it may be printed and distributed to the membership in advance of the Annual Meeting in January 1919, at which meeting it will be presented for discussion.

Chicago Technical Societies Organize for War Work

Representing an effort to coöperate effectively and vigorously for war work, an important joint war committee has been formed by representatives of technical societies centered in Chicago. The movement was started by the military committee of the Western Society of Engineers, and at the invitation of that committee several meetings have been held at the Chicago Engineers' Club. As a result, the "War Committee, Technical Societies of Chicago," to quote the official name, was organized June 4, 1918.

The purpose of this organization is "to enable the technical societies of the Chicago zone to call into play the efforts of the members of the various societies herein represented as occasion may arise and to coördinate their activities in the most effectual manner to help win the war." It is not proposed to attempt any novel "stunts," but rather to place at the disposal of the United States Government and other authorized agencies the combined strength and resources of the Chicago technical societies for war work as need may arise.

The following member societies are coöperating in the new war committee:

Western Society of Engineers
Structural Engineers' Association of Illinois
Society of Industrial Engineers
Illinois Society of Engineers
Illinois Society of Architects
The American Railway Engineering Association
The Swedish Engineers' Society of Chicago
Illinois Chapter, American Institute of Architects
Chicago Section, American Society of Mechanical Engineers
Chicago Section, American Chemical Society
Chicago Section, American Institute of Mining Engineers
Mid-West Section, Society of Automotive Engineers
Illinois Association of American Society of Civil Engineers
Chicago Section, American Society of Heating and Ventilating Engineers
Chicago Section, American Society of Refrigerating Engineers
Chicago Section, Steel Treating Research Society
Chicago Section, Illuminating Engineering Society
Chicago Chapter, American Association of Engineers.

Officers of the war committee have been elected as follows: Chairman, F. K. Copeland; vice-chairman, W. L. Abbott; secretary, Edgar S. Nethercut; treasurer, William A. Fox. The executive committee consists of F. K. Copeland, W. L. Abbott, William Hoskins, C. A. Keller, Charles E. Lord, C. F. Loweth, Isham Randolph and Richard E. Schmidt. The address of the secretary of the war committee is 1735 Monadnock Block, Chicago. (*Official Bulletin*, June 22, 1918, p. 22)

War Work of Federal Board for Vocational Education

Since coming into existence one year ago the Federal Board for Vocational Education has organized its work in every state of the Union, and has rendered substantial assistance to the war-making branches of the Government through training men for special duties.

Under supervision of the board, war-emergency training classes for conscripted men have been organized in secondary schools and a series of war-emergency training courses has been prepared, not only for training under direct supervision of the board but in classes organized by the War Department among enlisted men and for classes conducted on a commercial basis under private civilian control.

Emergency war-training bulletins prepared by the Federal Board include announcements of training courses in shipbuilding for shipyard workers; mechanical and technical training for conscripted men (Air Division, United States Signal Corps); training for motor-truck drivers and chauffeurs; for machine-shop occupations, blacksmithing, sheet-metal working, and pipe fitting; for electricians, telephone repair men, linemen, and cable splicers; for gas-engine, motor-car, and motorcycle repair men; for oxy-acetylene welders; and for airplane mechanics, engine repair men, woodworkers, riggers and sheet-metal workers.

The preparation of these courses and the organization of training classes have been undertaken at the request of and in coöperation with the Signal Corps and the Quartermaster Corps in the War Department and the United States Shipping Board.

In June 1918, 12,000 men had been trained through the Federal Board and state authorities for vocational education and turned over to services—6000 in mechanical lines, 5000 in radio work for the Army, Navy and mercantile marine, and 1000 in clerical occupations for Quartermaster Corps work. It is estimated that an additional 3000 men have been trained by private agencies through impetus given to the work by the Federal Board, and that, when the complete reports for May are in, the number in training will be shown to be at least 7500. On June 13 the May reports showed 165 radio classes operated in 38 states and 172 mechanical classes in 49 communities distributed over 14 states. Contracts now in force provide for the training of 100,000 men during the current year. (*Official Bulletin*, July 17, 1918, p. 19)

Military Instruction Planned for College Students

In order to provide military instruction for the college students of the country during the present emergency, a comprehensive plan will be put in effect by the War Department, beginning with the next college year, in September 1918, in connection with institutions of collegiate grade. The details remain to be worked out, but in general the plan will be as follows:

Military instruction under officers and non-commissioned officers of the Army will be provided in every institution of college grade which enrolls for the instruction 100 or more able-bodied students over the age of eighteen. The necessary military equipment will, so far as possible, be provided by the Government. There will be created a military training unit in each institution. Enlistment will be purely voluntary, but all students over the age of eighteen will be encouraged to enlist. The enlistment will constitute the student a member of the Army of the United States, liable to active duty at the call of the President. It will, however, be the policy of the Government not to call the members of the training units to active duty until they have reached the age of twenty-one, unless urgent military necessity compels an earlier call. Students under eighteen and, therefore, not legally eligible for enlistment, will be encouraged to enroll in the training units. Provision will be made for coördinating the Reserve Officers' Training Corps system, which exists in about one-third of the collegiate institutions, with this broader plan.

This new policy aims to accomplish a twofold object: first, to develop as a great military asset the large body of young men in the colleges; and second, to prevent unnecessary and wasteful depletion of the colleges through indiscriminate volunteering, by offering to the students a definite and immediate military status. Those who do not graduate this spring should be urged to continue their education and take advantage of this opportunity to serve the nation.

Training camps to fit men to act as assistant instructors in the new Students' Training Corps are now being held at Plattsburg, N. Y., Fort Sheridan, Ill., and Presidio, Cal. Courses at these camps will end on September 16.

The character of the training given in the Students' Army Training Corps will depend on the kind of unit organized in the particular institution. The standard time to be allotted to military work will be ten hours per week during the college year supplemented by six weeks of intensive training in a summer camp. The ten hours a week will not include the hours of outdoor work in drill. The summer camps will be an important feature of the system. These will be active for six weeks, and there will be an intensive and rigid course of instruction. The plan provides approximately 650 hours of military work per annum.

Salvage of Waste Material Made Profitable in England

Consul Augustus E. Ingram, at Bradford, reports:

The National Salvage Council is now urging all local authorities to recover for utilization waste and dormant materials hitherto regarded as "refuse." A definite national use has been found for many of these articles, and by well-organized collections and proper treatment not only have national resources been conserved, but a reduction has been effected in the tonnage required for the importation of new raw material.

Conferences with municipal authorities have been held in various cities. In certain salvage operations, such as retinning old cans, large authorities could put down a plant that neighboring small authorities or townships could utilize. (The Director of National Salvage is about to issue particulars as to the best method for dealing with this material, so as to reclaim not only the steel, but also the tin and solder.)

The advice given at the beginning of the war to "burn all refuse" is now obsolete. For instance, waste paper, if properly utilized, saves a great deal of shipping. At present only one-third of the paper is returned for trade use, although 365 trades are absolutely dependent on paper. Some authorities are paying a bonus to their employees for bringing in waste paper from the refuse. In Shipley, 80 tons of waste paper were collected in 1917, and that, including rags, realized £641 ($3119). In Bradford last year 75 tons of paper were collected from various public departments in the city, and realized £430 ($2093). The pulping mills now established in the country are a valuable new industry.

A pamphlet has recently been issued to local authorities by

the National Salvage Council offering many suggestions on the collection and utilization of waste and dormant materials. Among other things it states that organic refuse is needed for the extraction of glycerine and for feeding pigs. Grease traps to save the grease from dish washing at hotels, etc., are suggested. All available bone material should be saved; at present only about half such available material is recovered. Fish waste should have the oil extracted and a meat food suitable for feeding animals and poultry made from the residue; at Liverpool a plant has been installed for this purpose, and the fats obtained find a ready sale at £80 ($389.32) per ton, while the meal is retailed at about £21 ($101.20) per ton.

The municipal destructor works at Bradford is doing excellent waste-reclamation work. Ashpit refuse, after the old cans and metal are sorted out, is utilized as fuel for operating the reclaiming machinery. The clinker from the furnace is ground into a coarse grit and sold for use in braking tramcars and fine ashes are utilized in the manufacture of disinfectant powder. Animal refuse is subjected to steam heat and disintegrated, yielding finally tallow, bone meal, and meat meal. (*Official Bulletin*, June 25, 1918, p. 16)

British Thermal Gas Unit Proposed as U. S. Standard

The Fuel Administration issues the following:

The proposed order of the United States Fuel Administration, making a universal British-thermal-unit standard of 528 in the manufacture of gas in the United States, was discussed at a conference held in the office of Mark L. Requa, director of the oil division of the Fuel Administration. Representatives of the public-utilities commissions of New York, Illinois, Pennsylvania, Maryland, New Jersey, Wisconsin, New Hampshire and Massachusetts were present, together with representatives of the War Department, Council of National Defense, and the war-service committees of the gas-making industry.

Mr. Requa explained that the purpose of the proposed order was to conserve oil; that the standard as adopted in the proposed order was the same standard as that now in effect in the State of Massachusetts; and that this standard was for all practical purposes the standard adopted by the French Government after an investigation extending over a period of years. The public-utilities commissioners present expressed themselves as being entirely willing to coöperate in the Fuel Administration's effort to conserve oil. Several of them requested the privilege of presenting suggestions in writing, which they thought would tend to make the proposed order more definite.

When the question of the price at which gas was to be furnished the public under the new standard came up for discussion, Mr. Requa said the public-utilities commissions of the various states should settle the matter for themselves—that the Fuel's Administration's principal interest was in reducing oil requirements to the minimum.

The proposed order would supersede all previous standards for candlepower and British-thermal-unit value in artificial gas. A British thermal unit is the amount of heat required to raise 1 pound of water 1 degree in temperature. (*Official Bulletin*, June 26, 1918 (p. 11).

Conference on Metal-Working Machinery

The War Industries Board announced today that the methods for increasing the output of plate-working machinery to meet the unusual demands, principally of the Navy and the Emergency Fleet Corporation, were discussed at a meeting of such tool builders with representatives of the War Industries Board, army and navy engineers, the Emergency Fleet Corporation and some of its sub-contractors. Probably 95 per cent of the manufacturers of punching and shearing machinery, bending rolls, plate planers, spacing tables, etc., were represented.

Suggestions for increasing the output included: more intensive manufacturing by eliminating the usual large variety of tools and concentrating on the production of a limited variety, and the distribution of contracts to concerns that have no urgent war contracts but which, with the aid of patterns, drawings and the coöperation of regular manufacturers, could produce standard equipment. It is hoped in this way to advance the general war program.

To carry out the suggestions adopted by the meeting a committee of manufacturers was appointed to work in conjunction with G. E. Merryweather, chief of the machine-tool section of the War Industries Board. This committee includes H. J. Bailey, of Hilles & Jones, Wilmington, Del., as chairman; W. R. Beatty, of the Beatty Machine & Manufacturing Co., Hammond, Ind.; W. H. Harman, of the Southwark Machine Co., Philadelphia; Walter D. Sayle, of the Cleveland Punch & Shear Works, Cleveland, Ohio; Fred C. Avery, of the Long & Allstater Co., Hamilton, Ohio. (*Journal of Commerce*, July 9, 1918, p. 3)

Lehigh University to Give Degree in Three Years

In order to meet the needs of the present war situation, Lehigh University will substitute, as a war measure, three-year courses in place of four-year as heretofore. By this means the student will gain one whole year of time in his life and save the cost of living expenses for one year without his being subjected to any serious additional strain in his work. By substituting three terms a year in place of two terms, and by shortening the summer vacation to one month, the University will be able to give the student the same course in three years that is now given in four.

Under the four-year system of two terms yearly of 17 weeks each, 34 weeks in a year, gave in the four years a total of 136 weeks, of which two weeks yearly, or eight weeks in the four years, were devoted to examinations, leaving 128 weeks for instruction. Without lessening the thoroughness of the different engineering and arts courses by introducing three terms of 14 weeks each, devoted entirely to instruction, 42 for the year, or 126 for the course, the work can be given in three years. This change involves the elimination of a little over two weeks yearly now given to final examination periods. Examinations will be taken care of by tests throughout the term. The proposed plan will allow one vacation of one week at Christmas and one of one week in the spring, with eight weeks in the summer, three or four weeks of which will be devoted to the required summer schools in practical work of the technical courses, leaving the men from four to five weeks' free time for rest and vacation—certainly an ample provision in this time of war strain, and perhaps at any time.

"Carry On" is the title of a new publication on the subject of the reconstruction of disabled soldiers and sailors. The magazine is a monthly message from General Gorgas, Surgeon-General of the U. S. Army, and published for him by the American Red Cross. It may be obtained without charge by addressing the Surgeon-General, U. S. Army, Attention Editor *Carry On*, Washington, D. C.

REVIEW OF ENGINEERING PERIODICALS

Aeronautics

The A. E. G. Bombing Biplane. Description, with illustrations, of one of the large German bombing planes. It is stated that judging from contemporary British standards of design the A.E.G. is, according to the official report, decidedly clumsy not only in detail work but also in appearance, while its performance is poor. Steel is used in construction to a very large extent while wood is introduced very sparingly and plywood is almost entirely absent. It is also quite inferior to the German Friedrichshafen machine as regards the useful load it can carry although the power plant is the same.

The following features of construction are of interest. The framework, possibly because it is made entirely of steel tubing, is formed as one unit from tip to tail. The cross and upright tubes of the framework are attached to the main booms by direct welding without the use of sockets, and single and double lugs are welded into the corners for the attachment of the bracing wires.

The method of carrying the engines is peculiar, the chief feature being the absence of any direct tie between the engine and the outer plane. In fact, the engines are supported entirely from the main spars of the lower wings with ties reaching out to the main booms of the fuselage. Each engine is supported from the front main spar by two pairs of V-struts meeting at a point and fixed to the spar by means of a ball-and-cup joint. A single pair of V-struts supports the engine from the rear spar, the connection with which is also made by means of ball-and-cup joint.

The one propeller which has been recovered has a diameter of about 10 ft. 4 in. and a pitch of 59.3 in. It is built up of ten laminæ, of which the first and tenth are of walnut, the second, third, fourth, sixth and ninth of mahogany, and the fifth, seventh and eighth of a different kind of mahogany, probably African. The thickness of the laminæ varies in a peculiar manner; the first is 0.73 in. thick, the second to the sixth are 0.80 in., the seventh and eighth 0.40 in., the ninth 0.80 in. and the tenth 0.83 in. thick. The official report surmises the enemy is either short of timber or has some highly scientific reason for varying the thickness, concerning which we have no knowledge. (*The Engineer,* vol. 125, no. 3258, June 7, 1918, pp. 484-486, 14 figs.)

Air-Propeller Performance and Design by the Specific-Speed Method, M. C. Stuart. The purpose of the paper is to develop and show a new method of treatment of the performance and design of geometrically similar air propellers. The method described is an adaptation and extension of methods which have been successfully applied to hydraulic turbines, centrifugal fans and centrifugal pumps; in particular, by the author in a paper on Centrifugal Fan Calculations by the Specific-Speed Method (*Journal of the American Society of Naval Engineers,* August 1916).

When the more usual type of propellers is applied to a machine the requirements of power and forward velocity of the machine are known and the rotational speed and diameter of the propeller are expressed in terms of power and forward velocity and the direct method of treatment is thus obtained.

The writer defines the specific speed N_s of a propeller operating at any given efficiency as the speed of a geometrically similar propeller which is of such a diameter D_s as to produce unit power at a unit velocity and with the same efficiency. Conversely, the specific diameter D_s of any propeller operating at a given efficiency is the diameter of a geometrically similar propeller which, when running at a speed N_s, will produce unit power at unit velocity and with the same efficiency.

The specific tip speed v_s of a propeller operating at any given efficiency may be defined as the tip speed of a geometrically similar propeller required to produce unit forward velocity at the same efficiency.

An interesting feature of the Specific-Speed method is the fact that the use of slip and slip function is not necessary.

The specific speed, specific diameter and specific tip speed of any type of air propeller, operating at any given efficiency, are defined as the speed, diameter and tip speed, respectively, of a geometrically similar propeller which will develop 100 useful (thrust) horsepower when the forward velocity is 100 m.p.h. Formulæ for these three specific units are derived from the laws of similitude as applying to propeller performance. From test data of any propeller of the type computations are made of the values of the specific units at various efficiencies; and the specific units and efficiencies are plotted in the form of curves, which, in connection with the formulæ, cover completely the design and performance of all propellers which are geometrically similar to the propeller tested.

It is believed that the presentation of the performance of propellers and the solution of problems by the Specific-Speed method may prove to be much simpler than the present methods which involve the use of coefficients and functions for the following reasons:

a The coefficients or functions are merely abstract numbers without any tangible significance, while the specific units used

in the Specific Speed method may be thought of as speeds and diameters for unit requirements of performance, and the actual speeds and diameters for any requirements of performance are simply proportional to the specific units.

b All problems in the performance or design of a group of geometrically similar propellers may be solved by the use of a single curve and the simple formulæ for the specific units.

c The characteristics of various types of propellers may be compared upon coordinates which show directly the value of the propellers in meeting any desired requirements of performance. (*Journal of the American Society of Naval Engineers*, vol. 30, no. 2, May 1918, pp. 315-333, 5 figs.)

THE AUSTRIAN BERG SINGLE-SEATER FIGHTER. The machine is of the single-seater fighter type, in which the pilot and top plane are so placed in relation to each other that the wing obstructs the view to a very small extent only. This has been accomplished mainly by making the body very deep and placing the pilot fairly high inside the body, the extra depth of the body being secured by deepening the turtle back which forms a very much greater proportion of the overall depth than is the case in most machines. The turtle back is different from the majority in that it does not, except in the front, cover the whole width of the flat top of the body, but comes to a point just in front on the vertical fin.

The pilot's seat is extremely comfortable and is provided with arm rests, enabling the pilot to rest one arm while working the control lever with the other.

The controls are mainly of the usual type, but, in connection with the lateral controls, the wing flaps are fitted with cranks recessed in slots in the planes; and there is a somewhat unusual arrangement whereby the *positive* cable is taken to the front arm of the crank, so that it is the *return* cable which pulls the wing flaps down. The reason for this may be found in the warped wing flap, which may conceivably have its outer tip tilted upwards to such an extent that the effect of moving the flaps is between a force acting downward on the flap moved upward before the flap on the opposite side which has been moved down simultaneously, receives an upward force.

Aerodynamically, the wings present an interesting feature. The upper surface of the wing section has a most decided return sweep beginning behind the rear spar and being of such a magnitude as to present a considerable area of concave surface.

The tail planes are built of steel tubing throughout and the fixed tail plane is of interest because of the fact that although it is built up of single steel tubes, the section is made cambered by bending the single tubes forming the ribs. Both upper and lower surfaces, therefore, have the same camber. The incidence of the tail plane is adjustable, but not during flight. (*Flight*, no. 491 (no. 21, vol. 10), May 23, 1918, pp. 555-557, 1 fig.)

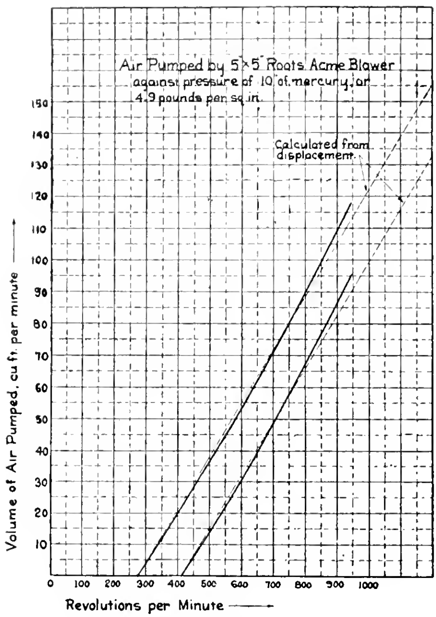

FIG. 1 RELATION BETWEEN QUANTITY OF AIR DELIVERED AND SPEED OF BLOWER

Air Machinery

TESTS ON ROTARY BLOWERS AND EXHAUSTERS. Investigation of the effect of pressure drop due to friction in the intake pipe and of actual and probable delivery with varying speeds.

Tests on rotary exhausters are seldom performed, partly because their discharge is pulsating and therefore nozzles or orifices cannot be used to measure the flow directly, and also because the rotary exhauster is in itself a meter of the displacement type, its speed being the measure of the quantity of gas delivered.

Usually the probable delivery is found by multiplying the difference between the slip speed and the actual speed by the displacement of the exhauster per revolution.

There is a belief, however, that other factors enter into the rate of delivery, and, among other things, that the pressure drop due to friction in the intake pipe reduces the delivery and counteracts the increase in efficiency due to the higher ratio of actual speed to slip speed.

In order to clear up these points Prof. W. Trinks (Mem. Am.Soc. M.E.) undertook a test at the Carnegie Institute of Technology on the delivery of a Roots rotary blower. The results of this test are shown in Fig. 1, which indicates the relation between the quantity of the air delivered and the speed of the blower.

In order to get a larger slip the head plates were removed from the blower and more red lead was put into the joint. The right-hand curve was obtained from this test; the character of both curves being exactly the same, however.

The length and shape of the inlet pipe were varied and the location of the pressure gage on the outlet was changed, but none of these changes had any appreciable influence on the shape of the characteristic curves.

From these curves it appears that the actual delivery falls below the probable delivery at lower speeds and rises above it at higher speeds, which is probably due to vibrations of the air column. As regards these vibrations, it is stated that they have a phase lag against the impressed vibration of the blower, which may explain why attempts to furnish an engine torque of the blower have not been successful.

Vibrations occur in the discharge pipe as well as in the intake and increase with the speed, but only up to the point where they become sound waves. Above this speed the pitch of the sound, that is, the frequency of vibration increases, but the amplitude, that is, loudness, remains constant, the maxi-

mum depending upon the ratio of outlet-pipe size to fluctuation of displacement. The smaller the outlet pipe for a given blower the worse the vibration becomes. (*The Blast Furnace and Steel Plant*, vol. 6, no. 7, July 1918, pp. 298-299, 3 figs., *e*)

Engineering Materials

Rubber Substitutes, Andrew H. King. Technical discussion of the factors and limitations to be considered in studying rubber substitutes. The writer believes that there is, as yet, no real substitute for rubber and states that oil substitutes are not in great demand in this country, because of the extensive use of reclaimed rubber and mineral rubber. He discusses the use of substitutes based on certain pitches, greases and waxes and briefly mentions the matter of glue substitutes. (*Metallurgical and Chemical Engineering*, vol. 18, no. 12, June 15, 1918, pp. 630-636, 1 fig., 7 tables)

Uses of Zirconia as a Refractory. Abstract of a paper recently presented by J. A. Audley before the refractory section of the Ceramic Society (British).

The paper covers such matters as properties and composition of zirconia, its technical applications and as a lining for industrial furnaces especially, and the use of zirconia in the manufacture of ferrozirconium to be ultimately used for the production of zirconium steels. It was stated that these steels are particularly hard and it is affirmed that 1-in. armor plate of zirconium steel is equal to 3-in. armor plate of the best German steels. The matter of the manufacture of crucibles of zirconia was also discussed. (*The Iron Age*, vol. 102, no. 2, July 11, 1918, pp. 72-73)

The Effect of Annealing on the Electrical Resistance of Hardened Carbon Steels, I. P. Parkhurst. Paper read at the metallurgical symposium of the American Chemical Society in Boston, September 1917, in which the writer comes to the following conclusions:

The total change in resistance increases with the carbon content of the steel. The change is very rapid at the beginning of the annealing and becomes slower as the resistance decreases. However, there was no indication in any case that the change was complete at the end of the test.

Since the resistance of a steel changes with the hardness, the curves are a fair indication of the varying rates at which hardened steels are softened by annealing at a constant temperature. The larger part of the change is completed within a few minutes, but the change is not entirely complete in 113 hours. (*The Journal of Industrial and Engineering Chemistry*, vol. 10, no. 7, July 1, 1918, pp. 515-518, 3 figs.)

Influence of Small Quantities of Some Metallic Elements on the Mechanical Properties of Brass, E. Millington. Description and data of experiments carried out to determine the effects of certain metallic elements on the mechanical properties of brass castings, the metallic elements investigated being tin, iron, manganese and aluminum. The addition of the first three elements to the copper-zinc alloy has been usually limited to 2 per cent, while manganese was carried to 2.81 per cent. In some respects the ternary alloys proved to have mechanical properties quite dissimilar from those of the original binary alloy. (*Journal of the Society of Chemical Industry*, vol. 37, no. 10, May 31, 1918, pp. 149 T-155 T, 3 figs., 3 charts, 2 plates)

Specifications for Aircraft Steels. Abstract of an address of Albert Ladd Colby at the last annual convention of the American Society for Testing Materials. Mr. Colby attended the Anglo-American and the International Aircraft Conferences, held in February and March, as the society's delegate. He stated that specifications were formally adopted and issued in April 1918 in the form of a pamphlet under the auspices of the British Engineering Standards Association, and gave some details of these standards. (*The Iron Age*, vol. 102, no. 2, July 11, 1918, pp. 70-71)

Tests Give New Information on Concrete Behavior. Abstracts of some of the papers presented at the joint meeting of the American Society of Testing Materials and American Concrete Institute.

Capt. L. N. Edwards, U. S. E. R., advanced the theory that the strength of cement mortars and consequently of concretes is dependent upon the quantity of cement in relation to the surface areas of the aggregates, consistency and physical qualities being equal. In other words, since the strength of mortar is primarily dependent upon the character of the bond existing between the individual particles of the sand aggregate, the optimum quantity of the cementing material depends upon the total surface area of the sand.

In fact, Captain Edwards stated that diagrams could readily be made showing the relation between granularmetric analyses of sands and their surface areas. To do this, actual counting of particles would have to be made at the beginning, but with these diagrams the proper quantity of cement for any given sand could readily be taken off.

P. J. Freeman, of the Pittsburgh Testing Laboratory, described the first year's results of tests of the five-year period of tests on the value of blast-furnace slag for a coarse aggregate in concrete.

In a paper entitled Fire Tests for Concrete Columns and based on tests made at the Pittsburgh Laboratories of the U. S. Bureau of Standards, Walter A. Hull, of the Bureau, indicates that the results so far obtained show beyond doubt that the design of a reinforced-concrete column, that is, the amount and disposition of the steel, is not nearly as important a factor in fire resistance as is the nature of the aggregate. It was further found that gravel-concrete columns showed a marked tendency in the concrete to break up early in the fire test.

Prof. D. A. Abrams, of the Lewis Institute, Chicago, showed through a series of elaborate tests that little additional strength can be attained by mixing concrete over one minute.

The same author presented a paper on the effect of age and storage on concrete strength. Data of many long-time tests taken from available literature showed a progressive increase in the compressive strength up to one, or in some cases, two years, with often a slight falling off beyond that period. When plotted to logarithmic curves, however, these showed a characteristic straight-line curve reducible to a formula with two constants, dependent on material, manufacture and storage.

To avoid certain difficulties with the standard Deval rattler when used for abrasive tests of road materials, Prof. H. H. Schofield, of Purdue University, has devised a modified rattler which is claimed to give a greater range of results. (*Engineering News-Record*, vol. 81, no. 1, July 4, 1918, pp. 48-49)

Internal-Combustion Engineering (See also Railroad Engineering)

Effect of Circulating-Water Temperature on the Lubricating Oil. Data of tests recently made by the Texas Company for the purpose of determining the effect of the temperature of the water in the circulating system on the condition of the lubricating oil.

The motor used was a Buda-type H. U. which employs a forced-feed oiling system at an oil pressure of 30 lb., the oil reservoir holding eight quarts.

The first test was made with the entire radiator front blocked by a sheet of cardboard and the radiator filled with hot water. The second test was made by removing the cardboard and filling the radiator at the start with cold water. During the two tests the atmospheric temperature was quite low. A medium-bodied motor oil was used for both tests.

The prevailing idea as to the relation between the temperature of the motor and the character of the lubricating oil has always been that a hot motor thinned the oil down rapidly and that a heavier oil was required than for a colder motor. It appears, however, that when lower-grade gasolines and kerosenes are used and partially vaporized fuel passes into the cylinder, the liquid portions or heavy ends condense on the cylinder walls and tend to wash the lubricating oil off the cylinder walls. The test made with the circulating-water temperature of 180 deg. fahr. showed a reduction of viscosity of the oil of only 26.3 per cent, while similar tests made with a circulating-water temperature of 102 deg. fahr. indicated a reduction of viscosity of the remaining oil 48.3 per cent.

In the opinion of the author these tests show the bad effect on the lubricating oil of unvaporized fuel in the cylinder, and also show that even if complete vaporization is not secured through the carburetor the fuel loss may be reduced by the use of higher circulating-water temperatures. (*Lubrication*, vol. 5, no. 8, June 1918, pp. 11-14, 1 fig., *e*)

Machine Parts

ELASTIC COUPLING OF PRIME MOVERS AND GENERATORS, O. Ohnesorge (*Zeits. Vereines Deutsch. Ing.* 62, pp. 77-78, Feb. 16, 1918). In a previous article [Abs. 703 (1916)] the author pointed out that the oscillations of generating plant are set up not only by irregular driving moment, but also by the presence of elasticity in the coupling between the prime mover and generator. On this account the provision of elastic couplings to hinder any hunting of the units may exaggerate the trouble that is to be counteracted unless certain specific conditions are fulfilled. It is necessary that the coupling employed should have a definite elastic constant, but the proposal that all such couplings that are obtainable on the market should be classified according to this feature is hardly practicable. As a matter of fact, the couplings that are obtainable have in general far too low a power of storing energy. The present article describes with illustrations the main features of the design of an elastic coupling with adjustable elasticity and having the property of causing the forces to act on a comparatively large volume of the working fluid that provides the elasticity, a defect of most commercial couplings lying in the fact that there is not room within the coupling to bring sufficient working fluid into action. In the design shown the coupling consists of two parts connected together by pistons working in cylinders containing oil kept under pressure by connection with an air receiver to which the cylinders are joined by an oil-filled pipe passing through a hollow shaft. The elastic forces are able to be adjusted, even during running, by means of the pressure and volume of the air-receiver. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 5, (no. 245), May 31, 1918)

MAXIMUM POWER AND SPEED OF BELT PULLEYS AND GEAR WHEELS, W. Kummer (*Schweiz. Bauzeit.*, 30, no. 5, 1917; *Elektrot. u. Maschinenbau*, 35, p. 629, Dec. 30, 1917). The author investigates maximum practicable values for power and speed in belt pulleys and gear wheels, basing his results upon the maximum peripheral force, P kg., transmitted. In belt drives P depends upon the tensile strength of the belt referred to the maximum peripheral force which can be transmitted. Using quadruple Ideal leather, total thickness 16 mm., with large pulleys, favorable transmission ratio, and high belt speed, a force of p = 55-56 kg. per cm. of belt width can be utilized continuously. If the belt width = b cm. $P = pb$. Let $q = b/D$, where D = diam. in cm. of the smaller pulley, then the moment M in kg-cm. on this pulley $= D^2qp/2$. Introducing the revolutions per second n, and an experimental factor K (in cm./sec.^{2}), we have $D^2 = K^2/n^4$, hence $K^2/n^4 = 2M/qp$. Since the horsepower $L = 2\pi nM/7500$, we have $Ln^3 = \pi qpK^2/7500$. Taking the highest values which can be realized in practice without going to extremes, we have $p \sim 50$ kg./cm.; $q \sim 0.75$; and $K \sim 8000$ cm./sec.^{2}, which yields $Ln^3 = 1{,}000{,}000$ approximately. This equation is plotted in the original. In gear drives, the force P operative at the periphery is $P = kb^2/\psi$ where b = width of gear wheel in cm., k = experimentally determined coefficient of bending strength of the teeth of kg./cm.^{2}, and ψ = ratio of wheel breadth to tooth pitch. By introducing the ratio $q = b/D$, the turning moment M in kg.-cm., is $M = D^3q^2k/2\psi$. Again, by introducing the revolutions per second (n), the constant K, and the horsepower L, we obtain the equation $Ln^5 = (\pi q^2kK^3)/(7500\psi)$, as expressing the relation between maximum power and speed for the smaller gear wheel. This expression appears also in the general form Ln^5 = constant, as the general relation between power and speed in standard electrical machinery. According to American practice in ship driving, suitable values for the constant in the above equation are: $(k/\psi) \sim 60/30 \sim 2$ kg./cm.^{2}; $q \sim 4.0$; $K \sim 53{,}000$ cm./sec.^{2}. Then $Ln^5 \sim 2 \times 10^{12}$.

The curves plotted between L and n for belts and gears from the above formulæ represent the virtual limits of present-day practice (say up to 5000 hp. for belts and 12,500 hp. for gears), assuming the same general construction in each type of drive from various horsepowers. Though these curves will change as practice advances, the general formulæ Ln^3 = constant and Ln^5 = constant will hold good for belts and gears respectively, so long as the appropriate factors are used in determining the constant term. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 5 (no. 245), May 31, 1918)

Machine Shop

SYMPOSIUM ON DROP FORGING. The fifth annual convention of the American Drop Forge Association was held in Buffalo, June 19 to 21, and in connection with this meeting was held the third annual meeting of the Drop Forge Supply Association. Numerous technical matters were discussed.

H. D. Savage presented a paper on Powdered Fuel for Drop-Forge Furnaces. He stated that powdered coal as now commercially developed is a practical, reliable and economical fuel for forge work. While it is not applicable to all existing plants, in those plants where it can be applied it may produce a fuel economy of 30 to 60 per cent over oil or coal burned by other methods, will increase production and greatly minimize the human element in the regulation of combustion. At the same time the author stated that he did not think the use of powdered coal was worked out very successfully in small shops because of the large expense involved in the installation. He also said that the American Locomotive Company is now using powdered-coal furnaces at its Schenectady plant and is equipping its whole forge shop with them. These furnaces are

being provided with stacks and forced draft to exhaust the ashes, and dust that formerly escaped into the shop is now kept in the furnaces and carried up the stack.

B. K. Read presented an interesting paper on Fuel Analysis of the Drop-Forge Plant. In it he pointed out the fact that a vast majority of manufacturers are still burning their fuel under conditions not conducive to the greatest possible economy. This applies not only to the case of coal, but to oil burning as well. He cited a case of one company where the following arrangement is used:

The company has an oil storage capacity of 120,000 gal., approximately a month's supply, in seven storage tanks. The oil house is connected with the steam-drop-hammer shop by a concrete tunnel in which are located the steam and oil lines. A duplicate system of motor-driven circulating oil pumps is located in the steam-hammer house, distributing the oil around the building in the steam-pipe tunnel, then to the board-hammer shop, and then overflowing back to the oil house. A pressure of about 20 to 30 lb. is maintained. From this circulating oil line risers are taken up to the various furnaces. A natural-gas line parallels the oil system so that either fuel may be used. Supplementing the oil-line system is a test oil line. A 300-gal. test tank is located in the oil house and a circulating oil line extends around the shop with a plug tee at each furnace. This enables any one furnace to be tested independently of the main oil supply. A test gas meter is provided for use in making tests when both gas and oil are used. Along with the oil and gas system is the air-pressure system. Air is delivered by a centrifugal compressor at 16 oz. pressure to five mains and then to each furnace.

The furnaces are built to withstand shocks and vibrations, and are completely encased in a steel box lined with firebrick. No induced air is allowed to enter the furnace. The slag opening is normally closed, and the only escape of the products of combustion is over the hearth. Above and in front of the hearth is a perforated air pipe deflecting the gases upward. In the upward path of the waste gases is placed a cast-iron pot or preheater through which the pressure air passes over baffles and is heated before it mixes with the oil and gas. Four sizes of furnaces are used and a spare one of each size is provided.

Tests carried out in this plant have shown a very material economy in fuel, due to the improved method of operation. Thus it was found that the furnaces were burning about as much oil during meal hours and the time between shifts as when there was steel in them. As a result, two men were assigned to watch the furnaces and shut them off during these periods. The air pressure is also a factor in furnace economy requiring an investigation of the air line.

George W. Pressell presented a paper on the relation between the highest quenching speed and maximum hardness. He stated that for hardening purposes an oil should be selected which will give a uniform quenching speed, will not produce gaseous vapors at low temperature, and will not oxidize or thicken with repeated use. The quenching speed of an oil depends on its refrigerating properties and also on its fluidity or viscosity.

He stated that exhaustive tests were made with an animal hydrocarbon oil which is a distillation of wool grease (no further data as to this oil appeared to have been presented) claimed to be an oil possessing a smaller percentage of residue and solid matter in suspension than any other oil known.

The average quenching speed for distilled wool-grease oil was 102 sec. The total variation in time of quenching in temperature of the bath ranging from 82 to 249 deg. was 9 sec., while cottonseed oil under the same conditions showed a quenching speed varying from 104 to 119 sec.

The ideal quenching medium for forgings would be a water-soluble material, which, when mixed with water, would give a quenching speed through the critical range equivalent to that of water, and from the critical range to the atmospheric temperature equivalent to that of oil. Mixtures of water and oil proved to be unsuccessful, however.

George C. Stebbins discussed the Care and Maintenance of Piston Rods. It is at present regarded necessary to use the highest grades of steel in piston rods, and the author found that his greatest trouble was caused by breakages of piston rings.

Referring to the maintenance of hammers, he recommended the use of a central oiling system, and explained a system of this type that he has installed in his plant. A steel tank is located near the steam line, a pipe running from this line into the oil tank to secure the proper pressure. The oil is carried in a line from the pressure tank, from which it is fed to the hammer. A $\frac{1}{2}$-in. line carries it to an ordinary sight-feed lubricator, and there is a $\frac{3}{8}$-in. line above the lubricator, which taps into the throttle. The system is so arranged that the oil supply for any hammer can be shut off. He said that in his plant many of the piston rods that are used had heads riveted on instead of using the solid rod, and he found this type of rods satisfactory. (Abstract made through *The Iron Age*, vol. 101, no. 26, June 27, 1918, pp. 1650-1654, *dp*)

Manufacture of Cast-Steel Chains. Chester K. Brooks. Description of the work of the National Malleable Castings Company in the experimental development of cast-steel chains.

The first problem was the working out of suitable foundry methods for producing chain links in sand molds and uniting them into continuous lengths of chains.

Because of the vital importance of sand castings in a product of this character all of the links are produced in dry-sand molds. The method of application of gates and risers required some study, but it is said that excellent results were obtained both in pouring through the stud and through the side of the link.

The article describes in some detail the methods of testing the product by both dynamic and static tests. The results of these tests are given in the form of tables.

The second part of the paper is devoted to a discussion of the design and manufacture of the M. C. B. coupler.

The limitations of the M. C. B. contour have imposed certain fixed dimensions upon the size of the hub of the knuckle, its weakest point, and have barred any substantial increase in section. At the same time the stress to which this hub is subjected is enormous. It was believed that the use of a material of high ductility would be capable of withstanding these severe shock stresses, as it was supposed a very ductile material would by its elongation absorb some of the shock and so save itself from rupture. The difficulty with this is that the major part of this elongation is available only after the elastic limit of the material has been passed.

Two possible solutions for this problem have been offered: one, a change in the contour of the knuckle, approved some years ago by the M. C. B. Association; and the other, the development of a new steel.

The author states that the experience gained in the manufacture of the coupler knuckle has been extensively utilized for development of the cast-iron chain. In this connection he believes that the standard M. C. B. drop-testing machine presents the most readily available machine for testing cast-steel chain links. (Paper read before the American Society for

Testing Materials, June 25-28, 1918, abstracted through *The Iron Trade Review*, vol. 63, no. 1, July 4, 1918, pp. 29-32, 19 figs., *gd*)

EFFECT OF MASS ON HEAT TREATMENT, E. F. Law. The usual method of experimental work on heat treatment of metals involved using test pieces of comparatively small size. Unfortunately, however, the heat treatment of large masses of steel presents many difficulties not met in the case of small masses. As a result some of the troubles in commercial heat treatment are due not to the lack of knowledge of the underlying phenomena, but to not always correct practical application of that knowledge.

The present investigation had for its purpose the obtaining of information which would enable one to understand the changes which actually take place in a considerable mass of steel during the stages of each treatment.

In this case the experimental cubes were 18 in. on a side, weighing 14.5 cwt.

These cubes, supported on knife edges, were heated in a gas-fired "treatment" furnace in which the flame did not come in contact with the cube. The cube was gradually raised to the temperature of 1650 deg. fahr.

The curves in Fig. 2 show the heating of these cubes. One of the most noticeable features about these curves is the rapidity with which the heat penetrates to the center of the cube. At 130 min. from the time of charging the center and half-way are almost at the same temperature, but at this point the absorption of heat due to the Ac change causes greater lag at the center than elsewhere and the two temperatures do not approach one another again till the lapse of another 70 min.

After being in the furnace for about $4\frac{1}{2}$ hours the cube is withdrawn and cooled one way or another. For air cooling it is placed on knife edges; for oil cooling it is plunged in the usual way in mineral oil having a specific gravity of 0.897.

The comparative cooling curves are given in Fig. 4. The rate of cooling with oil seems to have been surprisingly rapid in this test, due evidently to the fact that a very large volume of oil as compared with that of the metal was used.

A third cube was placed on knife edges and cooled by spraying water at a pressure of 10 lb. per sq. in. on the upper and lower surfaces.

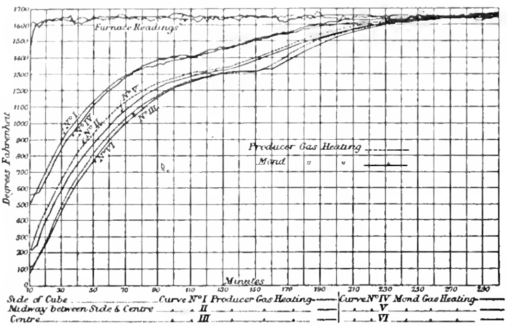

FIG. 2 HEATING CURVES OF STEEL CUBES 18 IN. ON THE SIDE

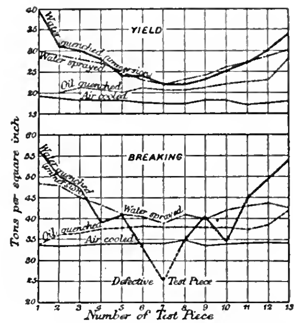

FIG. 3 DATA OF MECHANICAL TESTS OF SAMPLES FROM CUBES COOLED IN VARIOUS WAYS

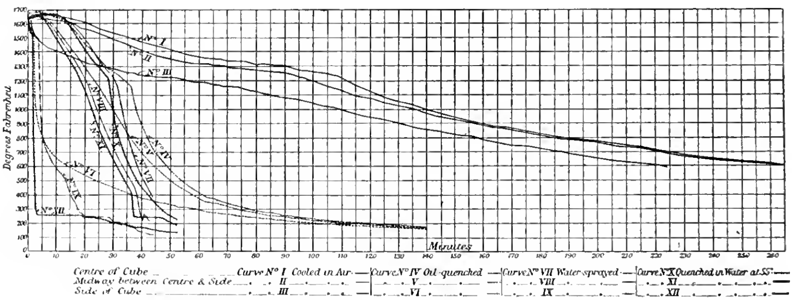

FIG. 4 COOLING CURVES OF 18-IN. STEEL CUBES IN AIR, OIL AND WATER

It is of interest to compare the oil and water curves. With oil—even in the center of the cube cooling takes place rapidly; but the evolution of heat at the Ar point is very noticeable. In the half-way curve, however, there is not the slightest indication of any recalescence. If it occurs (and presumably it does) it appears to be so evenly balanced by the conduction of heat to the outside that no change in the direction of the curve is noticeable. In fact, if the half-way curve were considered by itself it might be supposed that the steel possessed no critical point at all.

The curves VII, VIII and IX secured with water are in some respects similar to the curves with oil. The center curve again shows an evolution of heat and is not unlike the oil-hardening curve, although the rate of cooling through the lower ranges of temperature is more rapid. On the other hand, the half-way curve is totally different to that obtained by oil quenching. There is no sign of recalescence in the upper ranges, and the temperature falls evenly until about 450 deg. fahr. (232 deg. cent.), when there is a sudden acceleration in the rate of cool-

ing, followed by an abrupt halt at about 250 deg. fahr. (120 deg. cent). Somewhat similar features are shown in the curve representing the cooling of the outside of the cube.

The important difference between the two methods of cooling is to be found in the almost sudden slowing up of the cooling in oil shown in the lower ranges of temperature as compared with the cooling in water. Both in oil and water cooling, however, there is a period during which the metal in the center of the cube is cooling down more rapidly than the metal midway between the center and the surface.

A mechanical and photomicroscopical investigation of the metal was also carried out. The results of the mechanical tests are plotted in Fig. 3.

As might have been expected, the 13 results from the air-cooled cube gave practically identical results. In the case of the oil-quenched cube the breaking stress and yield are both raised, while the elongation is lowered, to almost the same extent in every test, the curves approaching a straight line. In other words, the effect of oil quenching is as apparent in the center of the cube as on the outside. In contrast to the results obtained by oil quenching, those obtained by water quenching show a very decided variation from surface to center of the cube; and this is most marked in the case of the cube plunged in cold water. The effect of the quenching is uneven, and the tests suffer from the lack of what might almost be described as "automatic tempering," which occurs in the lower ranges of temperature during oil quenching.

Sections were cut from the test pieces and examined microscopically. The photographs obtained show the characteristic appearance of magnifications of 100 diameters. The entire series are pearlitic, as might have been expected from the mechanical tests, and under higher magnifications they all, with one exception, show well-developed laminated pearlite. The exception is to be found in the surface of the cube quenched by plunging in water. In this case very little free ferrite is to be seen, and it is evident that the transformation has been very nearly arrested. This is confirmed by the fact that the surface of the cube was the only part which presented the slightest difficulty in machining.

The abrupt halt in the neighborhood of 250 deg. fahr. (120 deg. cent.) shown in the curves obtained from the water-cooled samples was totally unexpected and too striking to be passed over without notice. The writer does not claim to give an explanation of this fact, but points out that experiments repeated on 18-in. and 12-in. cubes showed that it occurred with remarkable regularity and was not affected by reasonable variation in mass. (Paper read before the Iron and Steel Institute, May 3, 1918, abstracted through *Engineering*, vol. 105, no. 2736, June 7, 1918, pp. 647-650, 2 figs., eA)

Steels for Gears and Their Treatment, Geo. A. Richardson. The writer divides all gears into two classes:

a Gears which are primarily used merely for the purpose of changing speeds, and

b Gears which are primarily used for the purpose of conveying power and must withstand the severe service conditions which are necessary.

In the first case, the cheapest material consistent with convenience is the best; in the second, the best material is the cheapest.

When the gears are to be used to convey power it becomes necessary to consider:

a Whether resistance to wear is the most important requirement, or

b Whether the resistance which the gear will offer to shock or sudden and excessive loads is of importance.

When resistance to wear is the most important consideration, the oil-hardened gear will, in the opinion of the author, give better service than case-hardened material. This opinion is rather contrary to the generally accepted view, and is based on the consideration that case-hardened material has an excessively brittle surface, and lacks the strength and toughness necessary to withstand the impact of shocks or heavy and excessive loads.

It was formerly believed that superior results could be obtained in gear trains by using varying grades of materials in the different gears, the idea being that those gears which tended to wear out fastest should be made of harder or better material. The latest information shows that when gears are operating under the same service conditions no advantage is secured by using gears of varying hardness.

As regards material, cast iron is the best material where it can be used, but all heavy gears for high, severe service have to be made of cast steel of either the straight-carbon or alloy types. While such gears can be cast in varying sizes for quantity production, drop forgings are preferable because they are cheaper to make, more uniform and stand up better in service.

For especially severe service, large-size gears have been manufactured with great success by using a nickel-chrome composition and air-hardening. In alloy steels for gears there are two general classifications to consider: case-hardening and oil-hardening. In some cases the choice between the two classes is determined by certain definite considerations. In many other applications, either class may be used. Plain carbon steel is used quite extensively in the case-hardened form, but not for the more severe kinds of service, because the core is very low in tensile strength.

An important point to bear in mind in connection with alloy-steel gears is that the lower the quenching temperature that can be used to get an effective hardness, the better the result. The higher nickels can be successfully hardened at the lower temperature. Chrome-nickel steels require a somewhat higher hardening temperature which decreases as the nickel content increases. Chrome vanadium requires the highest quench of all. For case-hardening it is not well to go above 0.20 per cent carbon in any of the alloys.

The alloy steels will stand a forging temperature of as high as 2200 deg. fahr., but they must be finished at a low temperature, the finishing temperature being the more important the higher the grade of steel.

The writer discusses in detail the case-hardening of high-grade steels.

As regards oil-hardening alloy steels, the writer states that the more sensitive of them, such as nickel-chrome compositions, absolutely require a double treatment. The first requirement is a preliminary treatment which may be a quench or an anneal to break down the crystallization set up during forging and bring the steel to a uniform cell size, though not a thorough grain refinement. In addition, it has been found desirable in the case of some alloys to give them a quench from the forging temperature in order to improve the condition of the steel. The forgings are taken directly from the forge and dipped into oil or water. They become black, but not cold and are then buried in ashes. The final treatment should be given at the lowest temperature that can be used and still give hardness.

As regards the relative merits of case-hardening and oil-hardening compositions, the writer states that, as a general

rule, the oil hardened gear can be counted on for more steady and uniform wear. Oil-hardened gears give a lower scleroscope hardness than case-hardened gears, but this is not a criterion of wearing quality, as the toughness of the material always enters in. (Paper presented at the Annual Meeting of the American Drop Forge Association, June 20, 1918, abstracted through *The Iron Age*, vol. 101, no. 26, June 27, 1918, pp. 668-670, 2 figs., *gp*)

Machine Tools

AUTOMATIC SPACING AND PUNCHING MACHINE FOR STRUCTURAL WORK, S. A. Hand. Description of a new machine which automatically spaces and punches variable structural members in both web and flange in one passage through the machine, and in any lengths and widths up to the maximum delivered by the rolling mills. All motions are electrically controlled from a central keyboard in about the same manner as musical instruments are played. (*American Machinist*, vol. 49, no. 1, July 4, 1918, pp. 1-8, 11 figs.)

HIGH-CUTTING-SPEED PLANER. The Powell Machine Company of Worcester, Mass., has developed a metal-planing machine claimed to give high cutting speed. This latter is secured by providing for accelerated platen travel after the cutting action is begun.

High speeds are difficult to secure in a planer because of the following factors: (1) the shock caused by the reversal of the platen at the return of the back stroke, and (2) the impact of the tool striking the work at high speed.

In the Powell planer automatic means are used to allow the tool to enter the cut at a low speed and to increase this speed thereafter.

On the usual driving shaft there are provided a pair of tight and loose pulleys for a return speed of 120 ft. per min., and a pair of tight and loose pulleys for a cutting speed of 60 ft. per min., in addition to which the planer is equipped with a second driving pulley and connections which increase the speed of the driving shaft to 180 ft. per min.

As the table reverses to take the cutting stroke the cutting speed is shifted to the tight pulley, which is provided with a ratchet. The tool now enters into the cutting stroke. After the platen has moved a predetermined distance a dog attached to the platen shifts a belt to the secondary high-speed pulley. This increases the speed of the driving shaft, which unlocks the ratchet pulley. By an arrangement of dogs placed at predetermined positions it is claimed that the cutting speed may be increased or retarded without perceptible shock or strain to moving parts during the cutting stroke. At the end of the stroke the final dog shifts the belts back to the loose pulley and the return is shifted to the tight pulleys. This causes the platen to return at normal speeed. (*The Iron Trade Review*, vol. 63, no. 1, July 4, 1918, pp. 22-23, 1 fig., *d*)

MILLING-MACHINE VISE AS A SPECIAL MILLING FIXTURE, Hugo F. Pusep. A practical discussion for the purpose of showing how the milling-machine vise may be made serviceable in place of the more expensive special fixtures. The writer called attention to the fact that, under the present conditions, production may be held up for considerable periods, because of the difficulty of supplying the machine shop with the necessary special equipment. The article is of a strictly practical nature. (*American Machinist*, vol. 48, no. 26, June 27, 1918, pp. 1101-1103, 6 figs.)

Marine Engineering

AIR SUPPLY TO BOILER ROOMS, Richard W. Allen. The writer discusses the subject of air supply to boiler rooms where closed stokeholds are employed, a matter of particular impor-

tance where oil fuel is used, as this necessitates high air pressures being maintained in the boiler rooms.

The writer gives formulæ for determining the air pressure required to produce a certain speed, and points out that within the range of speeds and pressures actually employed on board ship, the speed varies as the square root of the pressure difference, or for an exit nozzle consisting of a short cylindrical pipe with ends not rounded off an air pressure of 1 in. water gage would produce approximately a speed of 54 ft. per sec. (assuming a coefficient of flow of 0.8).

As regards the velocity of air in the air shafts, the speeds recommended are from 20 to 25 ft. per sec. The pressure required to produce this velocity is relatively small, 0.13 in. to 0.20 in. water gage, but increases in the ratio of the square of the velocity.

Tests recently made on four different classes of ships indicate that the air trunks are sometimes constructed so that they necessitate very high speeds with resultant excessive power losses. It must be remembered that to obtain a speed of air a pressure difference has first to be set up. The pressure energy is converted into velocity energy, the greater part of which is lost so that very little of it is converted back to pressure. Hence, the higher the air speed the greater the loss.

Enlargements and Restrictions in the Air Passages.—Tests taken for steam have shown that when a chamber, such as *C* in Fig. 7, is interposed in a pipe run, even if it be of no

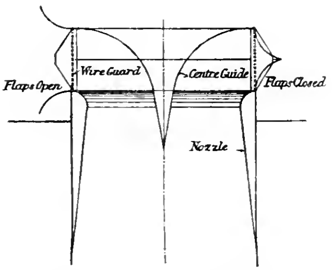

Fig. 8 New-type Cowl with Foul-Weather Flaps, with Center Guide and Nozzle

great length in the direction of the axis of the pipe run is sufficient to destroy completely the speed of the fluid approaching the chamber through the first portion of the pipe, and makes it necessary to have a further pressure drop expended in order to produce the speed afresh in the outgoing pipe.

Such sudden enlargement often presents itself where the air shaft leading from the top deck down to the fan compartment emerges into the fan compartment. There are also many points in the air passage where restrictions in area are frequent and the writer enumerates the chief causes which produce such restrictions.

As regards intakes, the writer calls attention to experiments made to establish the relative efficiency of their different types. The essential requirement in designing a betetr intake was to produce a guide which would perform the protective duty, but at the same time induce the flow of air into the shaft, especially when partly closed against the water.

The results of these tests are shown in Fig. 5, where data are given of the tests with the old-type cowl shown in Fig. 6 and the new type with central guide and nozzle shown in Fig. 8.

It is stated that the new design has an efficiency of 83 per cent against 35 per cent for the old design. In the new design the guides are of stream-line section and pivoted to the top of the air intake shaft so that they can be opened any desired amount. The other two recent innovations, namely, the center guide and nozzle, shown in Fig. 8, are embodied in the deck entry, the center guide in the form of a deflector or inverted pyramid attached beneath the cowl top, and the nozzle providing the *vena contracta* flow at the end of the entrance to the intake shaft.

In explanation of the manner in which the center guide and nozzle contribute to prevent loss of pressure, it has been proved that where these contrivances are not provided the whole of the space which they occupy is filled with eddy cur-

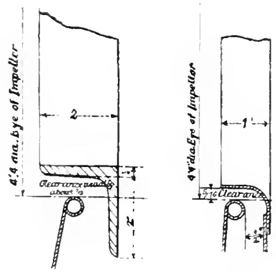

Fig. 9 To the left—Fan Inlet Ring of Incorrect Design; to the right Fan Inlet Ring of Improved Design

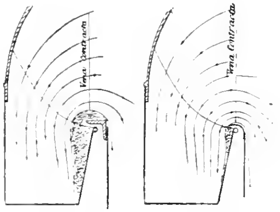

Fig. 10 Air Streams through Rings in Fig. 9

rents, which are continuously absorbing energy. The reason for the formation of the eddies is partly that the direction of the air is changed on entering the shaft and owing to its velocity sweeps round the corners, and partly owing to the law of *vena contracta* for the flow of all fluids, either liquid or gaseous, at entrance or exit of duct. The center guide and nozzle conform to the correct line of flow to prevent the formation of any eddies. Another improvement to which importance is attached is fitting the diaphragms, places athwart-ships, subdividing the air intake shaft. When a ship is traveling at a high speed there is a tendency for the air to rush past the intake without being drawn in, and for the air which does enter to bank up in the after side of the intake shaft, with a consequent tendency to starve the forward fans. By fitting diaphragms, the tendency to unequal air supply fore and aft will be efficiently counteracted, and all the fans will receive their due share of air.

Inlet Rings. In many cases where the fan has failed to deliver its desired output, it has been found on examination to be due to inlet rings badly fitted to the fan eye, or to the inlet ring being of unsuitable shape. The inlet ring should be satisfactory as regards: (1) correct clearance, (2) angle of entry,

and (3) the avoidance of sharp corners. An inlet ring of recommended design with correct clearances is shown at B in Fig. 9, while an incorrectly designed ring with the sharp corner is shown at A of the same figure.

Fig. 10 shows how the design of the ring affects the shape of the air stream. At A, corresponding to ring shown at A, Fig. 9, the effective area of the fan eye is reduced, the velocity of entry increased, and consequently the momentum of the air in the direction parallel to the axis of the fan. Fig. 10 at B shows how the *vena contracta* is increased in area and the velocity of entry reduced. Further, with the lower momentum and elimination of the outer eddies, the radius of change of direction of the air becomes smaller.

Some interesting tests are reported on steam consumption of the fan installation, which show that the increase in the steam consumption is about 20 per cent due to 1 in. vacuum on the inlet. On the other hand, it was found that the performance of a fan may be considerably improved both in output and efficiency through correct design of the fan casing and of discharge of the air from the fan case. Thus, in comparative tests with the fan first in a concentric casing and next in a volute casing, it was found that the improvement due to the volute amounted to 30 per cent in output and 9 per cent in efficiency. Still better results were obtained in another test.

The subject of deflectors on fan casings and of direction of rotation of the fan is discussed in considerable detail on the basis of an interesting e perimental investigation. (Paper read at the Spring Meeting of the Institution of Naval Architects, March 22, 1918, abstracted through *Engineering*, vol. 105, no. 2737, June 14, 1918, pp. 662-665, 18 figs, *ep*A.)

Mechanics

CHARTS FOR THE DESIGN OF HELICAL SPRINGS, M. M. Brayton. The purpose of the article is to bring spring formulæ to the practical man in such a way that he may be able to use them without going through a lengthy calculation on the slide rule or by hand. For this purpose the writer offers several simple graphical solutions.

Helical springs are usually made from wire of circular cross-section and may be designed for either tension or compression. The formulæ apply equally well in either case. In the design of these springs several factors have to be considered, namely, diameter of wire, outside diameter or mean radius of coil, maximum safe axial load, number of coils per inch, maximum safe shearing stress of the steel and the de 'ection of the spring under a given load.

The following formula expresses the general relation:

$$W = \frac{\pi S d^3}{8(D - d)}$$

where W = total safe load on spring in pounds
d = diameter of wire in inches
D = outside diameter of coil in inches
S = maximum fiber stress in pounds per square inch, taken at 60,000.

The writer gives a chart enabling one to find W by merely drawing two lines perpendicular to each other.

Since it is sometimes convenient to have the same formula expressed in terms of the mean radius of the coil rather than the outside diameter, the writer gives another chart based on the formula

$$W = \frac{\pi S d^3}{16 R}$$

where the same notation is used as above. Another chart is given to solve graphically the formula for the deflection of a spring under a given load.

The charts are not suitable for reproduction, but appear to be quite simple and convenient for use. (*American Machinist*, vol. 48, no. 24, June 13, 1918, pp. 1007-1011, 3 figs., *p*)

ON TWO-DIMENSIONAL FLUID MOTION, WITH FREE STREAM LINES, PAST AN OBSTACLE OF CURVED OUTLINE, J. G. Leathem (*Roy. Irish Acad.*, Proc. 34, pp. 11-39, March 1918). The author commences by giving in chronological order a list of papers to which he refers on the subject of two-dimensional flow of infinite liquid, with free stream lines, past a fixed obstacle of curvilinear outline. [For the author's previous paper on Two-Dimensional Fields of Flow, with Logarithmic Singularities and Free Boundaries, see Abs. 644 (1916).] In these researches there have been three distinct objectives: (1) A mathematical formulation, in terms of somewhat general functions, for any motion bounded partly by fixed and partly by free boundaries. (2) The exact or approximate adaptation of such a general formula to the case of an obstacle of arbitrarily assigned outline. (3) The choice of such forms of obstacle as shall correspond to liquid motions that can be precisely specified.

The exact adaptation of a general formulation to the case of an assigned obstacle seems bound to depend upon difficult functional equations, upon whose solution further progress must wait. The primary objective of a comprehensive formulation remains of fundamental importance, since such may well be the only possible point of departure for further progress in general theory, and the present paper offers a general formulation in terms of conformal curve factors—functions whose properties the author has discussed in previous papers. The method leads to expressions in terms of a definite integral involving a single arbitrary function of a real variable, and it is believed that in this form the properties of the relation between the fundamental variables are exhibited as simple as possible. From this formulation as starting point it has proved feasible to make a certain advance in knowledge, for there are obtained formulæ which specify the most forward points at which free stream lines can break away from an obstacle with smoothly curved sides. Attention is called to a probable connection between the positions of these points and the resistance which the obstacle offers to the stream when there are no free stream lines but the "wake" is in rotational motion; and a principle is deduced which may have important bearing on the problem of designing cylinders of small resistance—as, for example, struts for aeroplanes. The various sections of the paper respectively deal with: Notation and formulation; general formulæ; demonstration of generality; determination of points of departure of free stream lines from a curved obstacle; influence of the shape of the obstacle upon the divergence of the free stream lines, and the resistance to relative flow. The subject is treated mathematically throughout. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 5 (no. 245), May 31, 1918)

Railroad Engineering

WELDING TRUCK SIDE FRAMES, BOLSTERS AND ARCH BARS. Report of a special committee made to the Master Car Builders' Association at its meeting in Chicago, June 1918.

The tests were made at the Bettendorf Company's plant, Bettendorf, Iowa, and at the plant of the American Steel Foundries Company at Alliance, Ohio. At Bettendorf a 1500-ton hydraulic press was used, and at Alliance a Riehlé testing

machine of 1,000,000 lb. capacity was used in making the tests.

The following data show the nature of the work performed. The frame shown in Fig. 11 had a crack $3\frac{3}{4}$ in. long, yet under tests did not show signs of opening until a load of 195,000 lb. was applied, and opened $\frac{1}{8}$ in. under a load of 230,000 lb. The frame used in Test No. 8, Book A, with a crack $1\frac{1}{2}$ in long, took a load of 332,000 lb. before the fracture occurred. Any methods employed in welding or preventing cracks of this character from extending would permit the frame to remain in service with safety, as it is only in isolated cases that frames ever failed without giving sufficient warning that by ordinary inspection replacement or repair could be made to prevent accident or derailment. In many cases they have been kept in service until the crack commenced to open or extend into the

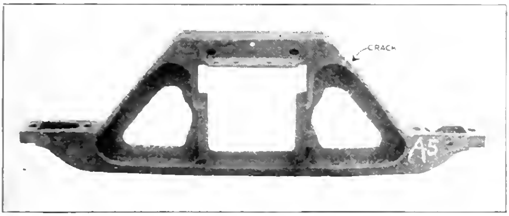

Fig. 11 Side Frame Before Welding

welding under load, as internal strain is liable to be set up through welding, which can be avoided by preheating. It is good shop practice to preheat cast steel and pressed-form bolsters and side frames.

The following summary and conclusions were presented by the committee in connection with one series of tests:

Of the 23 tests as per data herewith, there were 10 castings in which the original fracture had consisted of a complete break of the entire tension member, the fracture extending well into the web, with the exception ot test No. 19, the tension member of which was broken in from both sides, but not quite wholly fractured. (See photograph 1391.)

Of these 10 castings, the tension member of which was entirely fractured, only three broke in the weld under test. (See test No. 11, casting F-8; test No. 17, casting F-1; and test No. 20, casting F-3.)

If, in view of the data herewith submitted, it is desired to weld tension members that are almost wholly broken, with the fracture showing porosity, the welded portion should be built up to a considerable extent tor 2 in. or 3 in. over the surface to compensate for what may have been a weak point.

As a conclusion, it may be said that the tests clearly indicate that properly made welds are satisfactory.

In view of these tests and experiments, it is considered important that in making such welds consideration should be given to the tensile strength of the welding material as com-

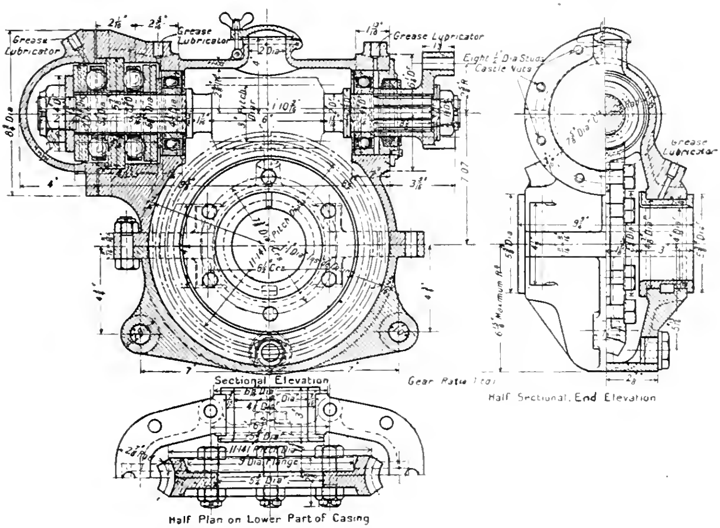

Fig. 12 Worm Drive of Bagnall Locomotive

vertical section before removal and without anxiety on the part of mechanical officers responsible for their performance.

A number of the castings tested were welded where broken entirely across the tension member, yet the welds were sufficiently strong so that under test the casting broke at some location other than the weld. Therefore the proper welding of side frames and bolsters would be permitted, the limit to prohibit welding to be when the strength of the weld would not equal that of the joining sections.

The committee also made certain recommendations as to the manner of carrying out the welding operation. Among other things, it states that great care should be exercised to prevent

pared with the tensile strength of the casting welded. If Norway iron or other welding metals of low tensile strength are used, the welds should be built up an amount sufficient to compensate for the total strength of section to be welded.

The Association by formal actions recognized as good practice and sanctioned the extension of autogenous welding to all parts of car equipment. (Abstracted through *Railway Age*, vol. 64, no. 25, June 21, 1918, pp. 1493-1496, 6 figs., *ep*)

Small Locomotives of Special Types. Description of the 40-hp. internal-combustion locomotive built by W. G. Bagnall, Ltd., Stafford, England.

The [illegible] is of [illegible] type, with cylinders 4[illegible] by 5 [illegible] and is [illegible] gasoline and run on kerosene.

The arrangement of [illegible] worm wheel is shown in Fig. 12. The thrust of the worm is taken up by ball bearings which are of the Hoffman type.

The cooling water, which is circulated on the thermosiphon system, is contained in a cylindrical tank arranged in precisely the same position as is the boiler in an ordinary steam locomotive. The tank, which is built up of two rings, 2 ft. 2⅝ in. and 2 ft. 3 in. internal diameter and 5 ft. long, has internally dished ends which serve as tube plates. There are in all 56 1¼-in. outside-diameter tubes, which are swelled to 1⅜ in. diameter at the front ends. They are of steel and No. 16 W. G. The internal faces of the tube plates are 4 ft. 8 in. apart. The cooling effect is obtained by the passage of the air through the tubes, no mechanical arrangement for forcing the air through the latter being found necessary. The capacity of the water tank is 113 gal. The exhaust pipe from the engine is taken up the chimney, which serves as a silencer. A branch from the exhaust pipe is taken to a whistle which is operated

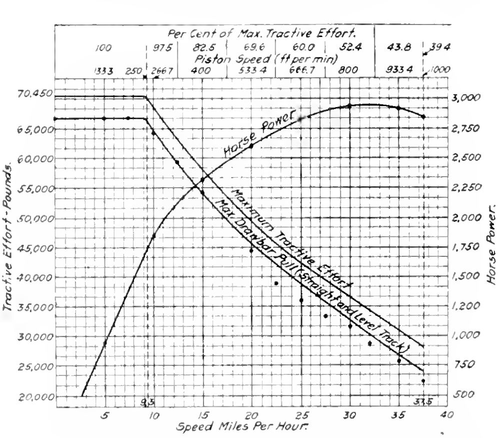

FIG. 13 TEST RESULTS SECURED WITH 2-10-2-TYPE LOCOMOTIVE ON THE UNION PACIFIC ON HEAVY GRADES

by cord from the cab. The arrangement of all the control levers in the cab follows closely steam-locomotive practice and appears to be excellent in every way.

In the same article is described a fireless locomotive built by a British concern. It is claimed to be the smallest fireless locomotive, from the point of view of weight, which has ever been constructed. In working order it weighs only 3½ tons. The engine is carried on four wheels, but only one exhaust is driven. The outer casing is of canvas soaked in boiled oil and painted; the cab is of wood and the buffers are of special shape and material, the plungers being of lignum-vitæ backed up by Spencer springs. (*Engineering*, vol. 125, no. 3256, May 24, 1918, pp. 442-443, and 448, 7 figs., *d*.)

TESTS WITH 2-10-2 LOCOMOTIVE ON THE UNION PACIFIC. Data of tests made with one of 27 engines built last year by the Baldwin Locomotive Works. The new engines were designed to be used over a reconstructed section on the Union Pacific between Ogden, Utah, and Evanston, Wyo. They were designed primarily to move the same tonnage eastbound over the new line with a ruling grade of 1.14 per cent compensated for curvature that the Mikado locomotives handle over the lines with 0.83 per cent grades. It was also desired to eliminate helper service on this district which has several difficult grades.

In tests the 2-10-2-type locomotives handled 1800 tons eastbound over this division (some of the grades are still 63 ft. per mile, uncompensated for curvature) at an average running speed of 15 m.p.h. with the coal consumption of 358.4 lb. per thousand gross ton-miles.

The curves in Fig. 13 show the tractive effort and drawbar pull developed and the horsepower. A maximum of 2940 hp. was developed at a speed of 30 m.p.h., which is at the rate of 1 hp. for every 121.6 lb. weight of the locomotive in working order, an unusually good performance.

The article describes in some detail the construction of this type of locomotives, and gives the principal dimensions and ratios of the locomotives. (*Railway Age*, vol. 64, no. 26, June 28, 1918, pp. 1572-1574, 5 figs., *ed*)

Refrigeration

COLD ACCUMULATORS AND THEIR APPLICATION, Ernest S. H. Baars. The article discusses the purposes of temperature hold-over tanks used in the refrigerating industry and describes a new hold-over tank which uses a weak calcium chloride solution in frozen state. The physical phenomena involved are discussed.

The term "cold accumulator" sounds paradoxical, because technically speaking it is not possible to accumulate cold. What is actually meant is a surplus refrigerating capacity stored up for use later on. The apparatus may also be called a "hold-over tank," because it keeps the room cold during the short period while the refrigerating plant is shut down. Such hold-over tanks are used principally in connection with small refrigerating plants which are not operated continuously. They are also desirable for automatically controlled refrigerating plants to prevent excessively frequent starting and stopping of the compressor and wearing out of the control apparatus.

Hold-over tanks may be divided into three types. The first

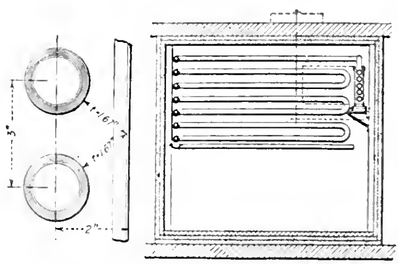

FIG. 14 HOLD-OVER TANK (TO THE LEFT, SPACING OF COILS; TO THE RIGHT, SECTION OF TANK)

is the brine tank. The second is a tank with the requisite amount of evaporating coils and a highly concentrated solution of chloride of calcium brine. While the machine is running the brine is cooled down to about 20 deg. fahr., and during the remainder of the way, when the machine is shut down, the heat that enters the room through the walls is absorbed by the cold brine in the tank, until the latter reaches a temperature when the refrigerating machine must be started again.

Several years ago the writer designed a third type, the working of which is based on a different principle. Instead of using a strong solution of calcium chloride, he uses a weak

solution and freezes it. For the successful operation of the hold-over tanks with frozen brine, tanks must have a special shape. Because of the fact that when a solution is frozen very slowly the water in it is frozen out and the salt crystals fall to the bottom of the vessel, it is essential that no brine be located too far from the evaporating pipe. By this means the salt crystals are kept in the ice and are ready to go in solution with the water as soon as the temperature rises.

Another feature is the flexibility of the walls of the tanks where corrugated sheets are used, thus preventing bursting through the expansion of the ice. Fig. 14 gives an idea of the construction of the tank.

The writer discusses in some detail the molecular movement of liquids as affecting the freezing point of solutions. (Paper read before the Engineers' Society of Milwaukee, abstracted through *Power*, vol. 48, no. 1, July 2, 1918, pp. 31-33, 2 figs. *d*)

Steam Engineering

Effect of Feedwater Temperature and Rate of Injection Upon Steam Flow, Frank G. Philo. The writer shows that under any given condition the actual output of the boiler expressed in B.t.u. absorbed per unit of time is constant, regardless of the rate of feeding and the temperature at which boiler feedwater is injected. At the same time boiler output expressed in pounds of steam per unit of time varies widely with changing feedwater temperature and rate of feedwater injection.

The normal condition is considered to exist when the feedwater is fed into the boiler at the same rate at which the boiler is steaming, while any rate of feedwater injection above or below normal will increase or decrease the rate of boiler steaming and the amount of water in the boiler.

As regards feed temperature, it is stated that when it is the same as the temperature of the water in the boiler, feedwater injection does not affect the rate of steaming, but when the feedwater is higher in temperature than the water in the boiler an increase in steam flow occurs upon feeding water into the boiler.

The following formulæ and chart (Fig. 15) have been developed to show the magnitude of the above described effects.

H = total heat above feedwater temperature of 1 lb. of steam

L = latent heat of 1 lb. of steam under given conditions plus B.t.u. for superheating 1 lb. of steam (if superheated)

h = heat of feedwater from feed temperature to boiler temperature

R_s = rate of steaming

R_w = rate of feedwater injection

1 With feedwater shut off entirely, $R_s = \frac{H}{L} = 1 + \frac{h}{L}$.

2 The rate of feedwater injection that would decrease steam flow to the rate of R_s would be $R_w = 1 + \frac{L - R_s L}{h}$

3 The rate of feedwater injection that would cause steam flow to cease would be $R_w = 1 + \frac{L}{h}$. (R_s = zero)

4 Under any given condition the sum of the heat absorbed by the feedwater and the heat used in boiling the water equals the total heat, or H absorbed by the boiler. As a formula this would be written $R_s L + R_w h = H$.

For examples of the foregoing take the conditions of 100 lb. gage, saturated steam, and 60 deg. fahr. feedwater temperature. Then $H = 1189 - (60 - 32) = 1161$ B.t.u.; $L = 880$ B.t.u.; and $h = 281$ B.t.u.

1 $R_s = \frac{H}{L} = \frac{1161}{880} = 1.32$, the rate of steaming with no feed.

2 Let R_s = 50 per cent, then $R_w = 1 + \frac{L - R_s L}{h} = 1 + \frac{880 - (0.5 \times 880)}{281} = 2.57$, the rate of feed required to reduce the rate of steam flow to 50 per cent of normal.

3 $R_w = 1 + \frac{L}{h} = 1 + \frac{880}{281} = 4.13$, the rate of feed required to stop steam flow.

Variable feedwater injection with the steady load is inimical to uniform steam pressure, but with loads that have a periodic fluctation, as in rolling mills, properly handled variable feedwater injection aids in the maintenance of the steam pressure.

The above discussion emphasizes the necessity of giving closer attention to the matter of correct boiler feeding. (*Power*, vol. 47, no. 26, June 25, 1918, pp. 915-916, 1 fig., *pt*)

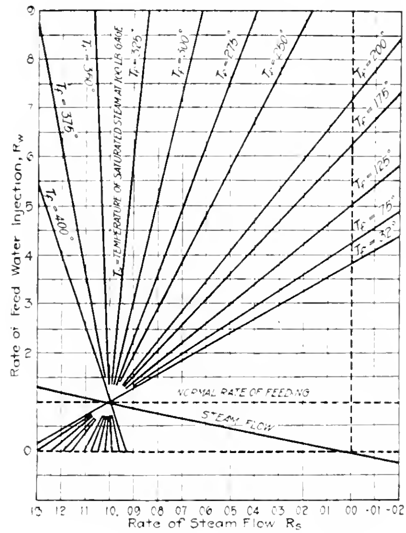

Fig. 15 Effect of Feedwater Injection on Steam Flow

Boiler-House Operation with Reference to Various Fuels, Knust (*Elek. Werk.* 6, 1916; *Elektrot. u. Maschinenbau*, 35, p. 47, Jan. 28, 1917, Abstract). It is economically preferable to distill hard coal rather than use it directly under boilers. All bituminous coals should be subjected to distillation. The author investigates the possibilities of substitutional fuels for boilers. For any given fuel there is direct dependance between the temperature of combustion, the quantity of air for combustion, the CO_2 content, and the temperature of the flue gases. The higher the CO_2 content and the lower the temperature of flue gases the more favorable the utilization of the fuel. The author gives formulæ for the initial temperature T, and by comparing this with the measured value, t, the loss of fuel may be determined at once. If $T = 2000$ deg. cent. and $t = 300$ deg. cent., the gross efficiency η of the firing is $(2000 - 300)/2000$, i.e., 85 per cent; for $T = 2000$ deg. and $t = 200$ deg., $\eta = 90$ per cent.

The author gives a table comparing gross efficiency, initial temperature, air surplus, and air and flue-gas quantities for a specified coal and various CO_2 contents. Formulæ are given for the air theoretically required for combustion and for the

vol[illegible] the [illegible]. A daily consumption of 10,000 kg. of coal when the CO_2 content is 12 per cent and the flue-gas temperature 200 deg. cent. corresponds to 33,400 kg. per diem when the CO_2 content is 4 per cent and the flue-gas temperature 400 deg. cent; the great saving under the former conditions is obvious. A table is given showing for the principal fuels, the calorific value, evaporation factor, maximum CO_2 content, initial temperatures and overall efficiencies. Charts for four of the most important of these fuels show the efficiency as a function of the CO_2 content and the flue-gas temperature.

A mixture of one part of coke to two of hard coal yields no difficulties in working; and a mixture of one coke to three of brown-coal briquets is also satisfactory. Thoroughly good mixing is the principal requirement. If coke be used alone, the grate, air supply, and stoking arrangements must all be modified. Using brown-coal briquets instead of hard coal adds about 60 per cent to the grate and 14 per cent to the smoke-

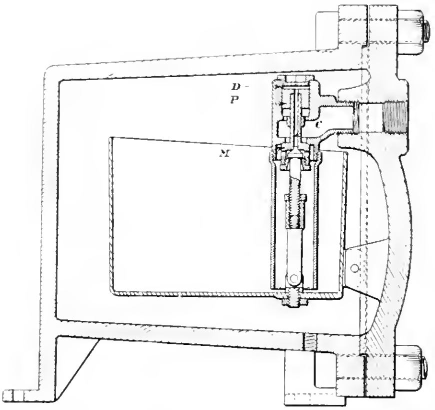

FIG. 16 BUCKET-TYPE STEAM TRAP WITH DOUBLE VALVE SYSTEM

stack duty. A formula is given expressing the cash value of substitutional fuels in terms of heating value. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 5 (no. 245), May 31, 1918)

STEAM TRAPS IN NAVAL SERVICE, F. G. Hechler. Description of the various classes of steam traps, with particular reference to their use in naval service.

As regards the capacity of steam traps, the author points out that while it is customary to designate steam traps according to the size of the inlet and outlet pipe connections, this method is not exact. Traps of the same nominal size often have widely different capacities. For instance, with the $1\frac{1}{4}$-in. traps tested at the Naval Engineering Experiment Station, the minimum capacity for any trap at 250 lb. steam pressure was found to be 2300 lb. of water per hour, while the maximum was 26,300 lb., or more than eleven times as much. This latter trap had a compound valve arrangement similar to that of Fig. 16. A capacity rating of a steam trap is of no value unless the pressure at which it was made is also given.

In order to secure satisfactory capacity results from steam traps it is desirable that they should be provided with interchangeable valves and valve seats adapted to various pressures. Also all valves should operate satisfactorily up to pressures somewhat higher than their rated value, which means that a 30-lb. valve should operate up to, say, 40 or 45 lb. for a margin of safety. This also makes it possible to grind in the valves when they become warm and even to rim out the seat. Both these operations are apt to enlarge the seating area of the valve, with the consequent danger of the trap becoming inoperative at the higher pressures.

The valve shown in Fig. 16, which gave such a large water discharge in the test above referred to, is representative of a type exclusively used in the naval service. With this type either a single- or compound-discharge valve may be used, and the latter gives the trap a very large capacity. This trap has the inlet and outlet connections in the cover so that it can readily be dismantled, provided the body is not fastened to the floor. The counterbored-recess type of gasket flange is used, and the best results will be obtained by carefully fitting the male and female ends so that there is only a small clearance.

The desirable features of a satisfactory steam trap for use in the naval service are summarized by the writer as follows:

Strong, rugged construction with properly designed gasket joints which may be kept tight without difficulty.

Inlet and outlet connections in the body of the trap.

The outlet valve located above the bottom of the trap where it is not likely to become clogged.

An accessible inlet strainer.

Powerful valve-operating mechanism so that the outlet valve may be large enough to give the trap ample capacity.

Proper functioning when oscillated.

A gage glass or other device for easily determining whether the trap is operating properly. For this purpose a hand gear for opening the outlet valve is also often convenient.

To secure the best results with traps they should be installed on the ship with the axis fore and aft to minimize the effects of a heavy sea. They should always be connected to the lines with unions, and every trap should be bypassed. (*Journal of the American Society of Naval Engineers*, vol. 30, no. 2, May 1918, pp. 239-254, 8 figs., *dcp*)

Thermodynamics

DEPENDENCE OF THE THOMSON-JOULE EFFECT FOR AIR ON PRESSURE AND TEMPERATURE FOR PRESSURES UP TO 150 ATMOSPHERES AND TEMPERATURES FROM — 55 DEG. TO + 250 DEG. CENT., F. Noell (*Zeits. Vereines Deutsch. Ing.*, 62, pp. 49-54, Feb. 2, and pp. 63-67, Feb. 9, 1918). The temperature change which a gas experiences by expansion without doing external work, i. e., the Thomson and Joule effect, is a phenomenon first observed by Thomson and Joule but only for moderate pressures and a small temperate range. A systematic investigation has been commenced by E. Vogel at the Munich Polytechnic Institute and participated in by the authors, employing much wider limits. All previous work on the subject had been so arranged that passage from a given high pressure to that of the atmosphere was made by a reducing valve whose low-pressure side communicated with the atmosphere. In this way it was not possible to measure the cooling effect at various pressures, and so study its dependence upon pressure and temperature. The innovations to the method now described in the paper provided for the adjustment of pressure differences on both sides of the reducing valve. The apparatus is discussed at great length and diagrammatically illustrated; the temperature measurements were made by means of a platinum resistance thermometer. Following this comes a full description of the experimental procedure accompanied by nine tables of results, the data being obtained at — 34 deg., — 55.4 deg., — 0.6 deg., 49.2 deg., 99.3 deg., 149.7 deg., 199.3 deg. and 249.9 deg. cent., respectively. The interpretation of the results oc-

cupies the second communication to which seven curves are attached.

The experiments have firmly established the dependence upon pressure and temperature of the Thomson-Joule effect for air between the above temperature limits. The general result may be expressed by the formula:

$$\triangle = dT/dp = \frac{A_1 - A_2p}{T} + \frac{B_1 - B_2p}{T^2} + \frac{C_1 - C_2p}{T^3} + D_1 - D_2p$$

where $\triangle$ is the cooling for 1 atmospheric pressure change, T the absolute temperature of the gas at the high-pressure side, p the arithmetic mean of the pressures on the high and low sides, dp the pressure difference, dT the corresponding temperature difference, and A_1, A_2, B_1, B_2, C_1, C_2, D_1, D_2 constants. At all temperatures investigated a linear decline of the cooling effect by the above formula the temperature drop caused by the reducing valve can be calculated for higher initial pressures by integration and has been depicted graphically, whereby it is seen that the proportionality of the cooling with the pressure difference at low temperatures and high pressures is no longer so exact. The results of this investigation agree with those of others. By extrapolation, a portion of the inverse curve has been determined. From the observed cooling effect the specific heat of air, C_p, was calculated for the region of the experiments with confirmation of the values obtained by Scheel and Heuse and by Swann for one atmosphere. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 5 (no. 245), May 31, 1918)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Rehearsal of Demobilizing Plan in Britain

Plans for the demobilization of the British fighting forces and the furnishing of civil employment for the men as soon as possible after the war are being worked out by the Government. The system as explained in an official statement is essentially as follows:

First, the men will be provided with substantial refreshment. A brief "fall in" will be called and there is to be a handing in of equipment. All must be given up except the uniform which the soldier is wearing and his greatcoat, the latter to be returned after a month of furlough, to which each man is entitled. A man will be allowed to keep his soldier clothes, with the exception of the greatcoat.

At the receiving huts of the dispersal depot the soldier will be expected to "hand over" all his accouterments. In another department each soldier is given an advance, and at the same time he gets a document, made out to the principal post office of the district to which he is going, enabling him to receive in three equal installments, during the period of his 28 days' furlough, the remainder of the money owing to him either on deferred pay, service gratuities or from any other sources.

On his application the man is presented with an out-of-work insurance policy, which is valid for a year. It is in the form of a document which entitles the holder to receive a fixed sum for a definite period, when unemployed, from a post office. The rate and the period will be fixed "when the time comes."

Finally, the men are grouped into different huts, each of which is occupied by those who are destined for a certain locality, and when the locomotive drags the empty carriages into the railway station, the Tommies enter them and are rapidly carried away to their friends and relations. This is the never-ending procession which will go on morning, noon and night, month after month, when the happy era of peace arrives.

It may be surmised with every degree of certainty, that all men on getting to the dispersal station may not be quite as fit as would warrant them being sent on post haste. That has also been provided for. Medical men will be there, and those who are not quite up to the mark will be detained in the hospital ward until able to travel.

At a camp not far from London there has been a rehearsal of the methods to be adopted to "disperse" the men. Big as was the job to get men into the army, it will be a bigger job to get them out of it, but the country may be sure that everything that can be done will be done to enable the soldiers to reach their homes and get employment with the minimum of friction.

The scheme is far-reaching in its ramifications. It has been carefully thought out by the British authorities, who have not only had to consider the position at home but also how it will fit in with the convenience of our French and Italian allies, with the Dominions overseas, with transport facilities from Salonika, Mesopotamia, and Palestine and from other parts of the world. Ships and railways will obviously play an important part in this huge undertaking; and so far as France is concerned the wharf space at the quays across the Channel will be a desideratum of first importance. It is expected, in fact, to dominate the situation. How long it will take to demobilize our army of millions is a question to which even those occupied in the task are not prepared to give a definite reply.

Eighteen dispersal depots are to be established in England, Scotland and Wales. They will be chiefly in populous districts, from which the majority of the fighting men have been drawn.

When the armies have been got away, the distribution of the soldiers into civil employment is a feature of the demobilization which rests with the Ministry of Labor. Up to the point of dispersal the army authorities will have acted in conjunction with the Labor Ministry and the trade unions. Then to some extent they part company. The basis of the whole scheme is industrial reconstruction and not military convenience. The problem of the Ministry of Labor is to tell us who the men are who are required first, and we have devised a scheme by which any man having his job ready for him will be released early. Those who have no occupations to go to will naturally remain in the army a little longer than those who have. Many may desire to remain with the colors, and with those it may be necessary to garrison India and to take the place of men there who will be anxious to get home.

On the other hand, men in trade and industry will be released with the utmost speed, as well as men needed in the factories and in other occupations which it is urgent shall get into their stride as early as possible.

The work involved in keeping records of what is likely to be the after-the-war conditions of millions has been prodigious. This has been mainly the business of the Ministry of Labor. Communication has been kept with employers, and happily, with few exceptions, there is a fine spirit in existence among them to welcome back the men who have left home to face the dangers of the battlefields and the sea.

No doubt when the demobilization comes about there will be many rough edges in the scheme which will need making smooth, but that can only be done as the result of actual experience. The rehearsals have been very successful and, in the opinion of those best able to judge, give promise of an equally successful realization when the moment of disbandment has been reached. (*Journal of Commerce*, July 1, 1918, p. 2)

Under the title, The Deepest Well in the World and the Next Deepest in America, Dr. Israel C. White, state geologist of West Virginia (Morgantown, W. Va.) has described (1) a well 7386 ft. deep put down by the Hope Natural Gas Co., eight miles from Clarksburg, W. Va., and (2) a well 7248 ft. deep owned by the People's Natural Gas Co., and situated five miles from McDonald, Pa. The paper, which has been printed as an illustrated pamphlet of 22 pages, was presented by Dr. White before the National Gas Association of America last May. The second of the two wells described is said to be the third deepest well in the world. (*Engineering News-Record*, July 18, 1918.)

LUBRICATION

THE LUBRICATION OF MACHINE SHOP EQUIPMENT. Lubrication, vol. 5, no. 8, June 1918, pp. 2 5. A general discussion of the subject presented by the Lubricating Engineering Association with the main purpose of showing how proper lubrication may help to eliminate noise and to prolong the life of machines and tools.

WASTE OIL TROUBLES, W. A. Taller. National Engineer, vol. 22, no. 7, July 1918, pp. 296-298, 1 fig.

MARINE ENGINEERING

WELDING SHIP'S PARTS TOGETHER, James G. Dudley. International Marine Engineering, vol. 23, no. 6, pp. 359-360, 4 figs. An account of the development of the electric welding of ships by the Emergency Fleet Corporation.

FERRO-CONCRETE SHIPS, T. J. Gueritte. International Marine Engineering, vol. 23, no. 6, pp. 329-334. Discussion of materials and systems of construction; plastered and molded ships; weight, cost and durability. Paper read before the North East Coast Institution of Engineers and Shipbuilders, Newcastle-upon-Tyne, March 1918.

GOVERNMENT DESIGNS AND BUILDS 3500-TON CONCRETE SHIPS. Engineering News-Record, vol. 81, no. 1, July 4, 1918, pp. 17-21, 7 figs. Shape and size of vessels under construction follow standard wooden ships of same tonnage. Usual concrete details adapted to sea-going ships.

DESIGN STEEL SHIPS FOR MAXIMUM EFFICIENCY OF BRIDGE-SHOP FABRICATION. Engineering News-Record, vol. 81, no. 1, July 4, 1918, pp. 5-12, 13 figs. Description of the fabricated-ship construction at the Hog Island plant and some of the features of construction.

MACHINE PARTS

INGENIOUS MECHANICAL MOVEMENTS, Franklin D. Jones. Machinery, vol. 24, no. 10, June 1918, pp. 902-908, 10 figs. Second of a series of articles on mechanism.

BEARINGS FOR MACHINE SHOP EQUIPMENT, Edward K. Hammond. Machinery, vol. 24, no. 11, July 1918, pp. 975-987, 21 figs. First of a series of articles. Deals with various forms of plain bearings which have demonstrated their ability to give satisfaction in service.

MACHINE SHOP

***DROP FORGING PROBLEMS DISCUSSED.** The Iron Age, vol. 101, no. 26, June 27, 1918, pp. 1650-1654.

GRINDING AND LAPPING THREADS, J. E. Lindgren. Machinery, vol. 24, no. 11, July 1918, pp. 1023-1024, 5 figs. Attachments, fixtures and laps used for producing accurate threads.

MANUFACTURING WRIGHT ROLLER BEARINGS. Machinery, vol. 24, no. 11, July 1918, pp. 1019-1021, 9 figs. Description of the processes involved in machining parts, heat-treating, assembling and inspecting.

OPERATING THE GRIDLEY AUTOMATIC TURRET LATHE—1, Douglas T. Hamilton. Machinery, vol. 24, no. 10, June 1918, pp. 926-931, 16 figs. Complete instructions for tooling, setting up, and operating. 2, July 1918, pp. 1016-1018, 4 figs. Examples of camming and setting tools.

Manufacturing Operations on Jewelry Settings, J. V. Hunter. American Machinist, vol. 49, no. 2, July 11, 1918, pp. 47-52, 13 figs.

Manufacturing the Curtiss Airplane Cylinder, II. The Water Jacket, G. A. Ranger. American Machinist, vol. 49, no. 2, July 11, 1918, pp. 62-65, 15 figs. Describes preparation of the Monel metal jacket and the brazing operations.

Work in a Texas Repair Shop, Frank A. Stanley. American Machinist, vol. 49, no. 2, July 11, 1918, pp. 53-56, 13 figs. Description of a varied line of work in the blacksmith shop and structural department of a large smelter; bending, forming and welding operations; some special tools.

Design and Construction of Work-Benches, Frank H. Mayoh. Machinery, vol. 24, no. 10, June 1918, pp. 880-886, 24 figs. Bench legs and tops; location of benches; portable work benches.

Metallic Electrode Arc Welds, O. S. Eschholz. Railway Mechanical Engineer, vol. 92, no. 7, July 1918, pp. 416-419, 7 figs. Suggestions for determining the quality of the joint; proper methods which will secure good results.

Fusion Welding Fallacies—1, S. W. Miller. Machinery, vol. 24, no. 11, July 1918, pp. 1014-1015, 5 figs. Some common beliefs and why they are unsound.

Arc Welding of Mild Steel, O. H. Eschholz. The Electric Journal, vol. 15, no. 7, July 1918, pp. 247-250, 13 figs.

*Effect of Mass on Heat Treatment, E. F. Law. Engineering, vol. 105, no. 2736, June 7, 1918, pp. 647-650, 17 figs.

Bluing Steel, W. B. Greenleaf. Machinery, vol. 24, no. 11, July 1918, pp. 997-998, 2 figs. Materials, arrangements and methods used on light sheet-steel work.

Heat Treatment of Axles, Dwight D. Miller. Railway Mechanical Engineer, vol. 92, no. 7, July 1918, pp. 419-421, 3 figs. The scientific heat treatment of locomotive and car axles made possible by use of electric furnace.

MACHINE TOOLS

A New Nut Making Machine. The Engineer, vol. 125, no. 3259, June 14, 1918, pp. 510-511, 3 figs.

*Designs High-Cutting Speed Planer. The Iron Trade Review, vol. 63, no. 1, July 4, 1918, pp. 22-23, 1 fig.

Intensive Production on Drilling Machines—1, Edward K. Hamilton. Machinery, vol. 24, no. 10, June 1918, pp. 914-921, 5 figs. Organization of the drilling department and use of special equipment on machine to adapt them for a wide range of work.
2, July 1918, pp. 1030-1034, 12 figs. Design of cutting tools and work-holding fixtures for handling turned lathe work on drilling machines.

The Inspection of Machine Tools, Ethan Viall. American Machinist, vol. 49, no. 1, July 4, 1918, pp. 13-17, 15 figs. Description of testing methods used in some well-known machine-tool-building shops.

War-Time Repairs in the Navy—III, General Repair Work, Frank Stanley. American Machinist, vol. 48, no. 26, June 27, 1918, pp. 1091-1094, 10 figs. The making of small and medium-sized parts. Overhauling machine tools for ships.

Results of Faulty Tool Designing, F. B. Jacobs. Machinery, vol. 24, no. 11, July 1918, pp. 1028-1029, 9 figs. Examples of tools and fixtures that did not work, with reasons for failures.

The Wilt Process of Twist Drill Manufacture, Franklin D. Jones. Machinery, vol. 24, no. 11, July 1918, pp. 1007-1013, 11 figs. A process in which all machining operations on twist drills, except grinding, are done automatically.

Supports for Milling Machine Arbors, Luther D. Burlingame. Machinery, vol. 24, no. 11, July 1918, pp. 992-996, 18 figs. Historical review showing early designs with the development of types now used.

MEASURING APPARATUS AND METHODS

Example of Precision Gage Making. Machinery, vol. 24, no. 10, June 1918, pp. 878-879, 5 figs. Methods of making and testing a gage requiring unusual accuracy.

Universal Milling Machine Dynamometer, R. Poliakoff. Machinery, vol. 24, no. 10, June 1918, p. 932, 4 figs. Describes a dynamometer designed for measuring the pressure that a milling-machine cutter exerts on the work and on the various parts of the milling machine through the work.

Indicator Gages Used in Gasoline-Engine Construction, C. C. Marsh. Machinery, vol. 24, no. 10, June 1918, pp. 910-913, 5 figs. Gages for inspecting cylinder depth, length, external diameter, cam lift, profile and eccentricity.

Contour- and Radius-Measuring Instrument. Machinery, vol. 24, no. 10, June 1918, pp. 898-899, 5 figs. Universal type of instrument for measuring irregular profiles, radius gages and contours that cannot be tested by ordinary measuring devices.

Distantiagraph, W. D. Farris. Proceedings of the U. S. Naval Institute, vol. 44, no. 181, March 1918, pp. 557-559, 3 figs. Describes an instrument designed to determine the actual distance a ship must pass over a light or point.

Gages and Thermometers, John E. Starr. Refrigerating World, vol. 53, no. 6, June 1918, pp. 11-12.

Viscosity Determinations in Absolute Units. Engineering, vol. 105, no. 2737, June 14, 1918, pp. 655.

MECHANICS

Non-Molecular Structure of Solids, Arthur H. Compton. Journal of The Franklin Institute, vol. 185, no. 6, June 1918, pp. 745-774, 15 figs.

Approximate Live-Load Stresses in Railway Bridges, H. R. White. Engineering News-Record, vol. 80, no. 24, June 13, 1918, pp. 1137-1138, 2 figs. Linear formula for floor-beam concentration giving shears and moments easily.

Designing Wall Beams in Concrete Flat-Slab Buildings, Albert M. Wolf. Engineering News-Record, vol. 80, no. 24, June 13, 1918, pp. 1124-1126, 3 figs.

Equivalent Uniform Loads for Concrete Beams, Albert J. Becker. Engineering & Contracting, vol. 49, no. 26, June 26, 1918, pp. 633-635, 3 figs. Method of calculating special beams with partial or non-uniform loads.

Formulas for Calculating Thickness and Reinforcement for Concrete Conduit, L. Robert de la Mahotiere. Engineering & Contracting, vol. 49, no. 24, June 12, 1918, pp. 591-593, 4 figs. A translation from Le Génie Civil. Based on assumption of empty conduit supporting a uniform load on upper half; thickness of conduit constant.

MILITARY ENGINEERING

Condotta e Osservazione del Tiro Terrestre, Giuseppe Fioravanzo. Rivista Marittima, Anno 51, no. 3, March 1918, pp. 173-190, 11 figs. An extensive mathematical article on land artillery fire.

MUNITIONS

Routing and Handling Shells, James Forrest. Machinery, vol. 24, no. 10, June 1918, pp. 922-925, 8 figs. General production methods and short cuts on larger shells.

The Manufacture of the Lewis Machine Gun, X. The Bolt and Feed Operating Stud—I, Frank A. Stanley. American Machinist, vol. 49, no. 1, July 4, 1918, pp. 25-29, 9 figs. Description of the machining operations.

Forging the U. S. 75-Millimeter Shell, Erik Oberg. Machinery, vol. 24, no. 10, June 1918, pp. 890-897, 20 figs. Fourth of a series of articles describing approved methods employed in the forging and machining of the U. S. 75-mm. shell.

By-Product Coke Industry in War Time, William H. Blauvelt. The Iron Age, vol. 101, no. 24, June 13, 1918, pp. 1544-1545. Importance of the by-product method in coal conservation; furnishing raw materials for high explosives; keystone products, bases of important industries. From paper read before the American Iron and Steel Institute, May 1918.

Sidelights on Winchester Gun Production, W. E. Freeland. The Iron Age, vol. 101, no. 24, June 13, 1918, pp. 1521-1526, 9 figs. Control of tools and gages; foremen held responsible for inspection; time-study methods and satisfactory results.

POWER-PLANT ENGINEERING

ESTIMATING POWER REQUIREMENTS OF A LOCALITY, Ludwig W. Schmidt. Power, vol. 48, no. 2, July 9, 1918, pp. 55-56.

PUMPS

A LOG BOOK FOR AN ELECTRICALLY DRIVEN PUMPING UNIT AT NEW BEDFORD, R. C. P. Coggeshall. Journal of the New England Water Works Association, vol. 32, no. 2, June 1918, pp. 173-179, 1 fig., 1 chart.

WATER-WORKS PUMP WITH HIGH EFFICIENCIES. Power, vol. 48, no. 1, July 2, 1918, p. 16, 1 fig. Results of efficiency tests of two 12-in. motor-driven centrifugal pumps.

RAILROAD ENGINEERING

STANDARDIZATION OF INDIAN RAILWAYS' LOCOMOTIVES, E. C. Poultney. Railway Age, vol. 64, no. 24, June 14, 1918, pp. 1425-1430, 9 figs., 3 tables.

*TESTS WITH 2-10-2 LOCOMOTIVE ON THE UNION PACIFIC. Railway Age, vol. 64, no. 26, June 28, 1918, pp. 1573-1574, 3 figs.

DESIGN AND MAINTENANCE OF LOCOMOTIVE BOILERS. Railway Age, vol. 64, no. 25, June 21, 1918, pp. 1522-1523.

SEMI-ELLIPTIC SPRINGS—MANUFACTURE AND REPAIR. Railway Age, vol. 64, no. 25, June 21, 1918, pp. 1528-1531, 10 figs.

*SMALL LOCOMOTIVES OF SPECIAL TYPES. The Engineer, vol. 125, no. 3239, June 14, 1918, pp. 507-510, figs. 19-26.

FEED WATER HEATERS, J. Snowden Bell. Railway Review, vol. 63, no. 1, July 6, 1918, pp. 14-16, 3 figs.

NORFOLK & WESTERN 267-TON MALLET LOCOMOTIVE, H. W. Reynolds. Railway Age, vol. 65, no. 2, July 12, 1918, pp. 59-63. Details of design of a 2-8-8-2 Mallet locomotive and tender built at the Norfolk & Western Shops, Roanoke, Va.

LOCAL STRESSES IN BOX BOLSTERS, L. E. Endsley. Railway Mechanical Engineer, vol. 92, no. 6, June 1918, pp. 343-348, 15 figs. Tests of loaded bolsters with Berry strain gage showing effect on strength of design details. Abstract of paper read before St. Louis Railway Club, May 1918.

THE RAILWAY SHOP TOOL ROOM, M. H. Williams. Railway Mechanical Engineer, vol. 92, no. 6, June 1918, pp. 335-340, 7 figs. The importance of the tool room and its equipment.

DRAFTING MODERN LOCOMOTIVES, H. W. Coddington. Railway Mechanical Engineer, vol. 92, no. 6, June 1918, pp. 331-333, 3 figs.; no. 7, July 1918, pp. 387-392, 10 figs. Improvements effected by a study of draft conditions on Norfolk & Western 4-8-2 type engines.

THE LIGHT RAILWAY ALONG THE BRITISH FRONT AT CLOSE RANGE, Robert K. Tomlin, Jr. Engineering News-Record, vol. 80, no. 25, June 20, 1918, pp. 1162-1169, 15 figs. Where and how lines are built; how maintained and how operated; what they have accomplished.

A WELL-ORGANIZED REPAIR SHOP. Railway Mechanical Engineer, vol. 92, no. 6, June 1918, pp 303-311, 15 figs. A study of methods followed in repairing locomotives on the New York Central at West Albany.

RECLAMATION ON THE SOUTHERN PACIFIC, Frank A. Stanley. Railway Mechanical Engineer, vol. 92, no. 7, July 1918, pp. 381-386, 12 figs. First installment. Describes the extensive salvage work done in the road's Sacramento shop.

DOINGS OF THE UNITED STATES RAILROAD ADMINISTRATION. Railway Age, vol. 65, no. 2, July 12, 1918, pp. 48-57. Action of freight classification, valuation, mileage, etc.

REFRIGERATION

*COLD ACCUMULATORS AND THEIR APPLICATION, Ernest S. H. Barrs. Power, vol. 48, no. 1, July 2, 1918, pp. 31-33, 2 figs.

STEEL FRAME REFRIGERATOR CARS, E. G. Goodwin. Railway Mechanical Engineer, vol. 92, no. 7, July 1918, pp. 401-405, 10 figs. Description of Norfolk & Western design with bunched insulation, insulated bulkheads and conduit floor racks.

STEAM ENGINEERING

INTERPRETING STEAM-TURBINE TEST CURVES, H. E. Brelsford. Power, vol. 47, no. 25, June 18, 1918, pp. 866-868, 5 figs. Brief description of standard turbine test curves and how they are derived and used in interpreting turbine characteristics.

*EFFECT OF FEED-WATER TEMPERATURE AND RATE OF INJECTION UPON STEAM FLOW, Frank G. Philo. Power, vol. 47, no. 26, June 25, 1918, pp. 915-916, 1 fig., 1 table.

IMPROVING PLANT CONDITIONS, A. W. Blom. Power, vol. 48, no. 1, July 2, 1918, pp. 11-12, 4 figs. How changes were made to prevent air from leaking past the end of chain-grate stokers. Description of a feed-water heater working on the jet-condenser principle.

REMODELING THE ST. LOUIS BADEN STATION, K. Toensfeldt. Power, vol. 47, no. 25, June 18, 1918, pp. 862-865, 4 figs. Remodeling a station of 3300 boiler horsepower at a total investment cost of \$177,500 for an estimated annual saving of \$11,797.

TABLE OF B.T.U.'S PER BOILER HORSEPOWER AT VARIOUS EFFICIENCIES, Charles H. Bromley. Power, vol. 48, no. 2, July 9, 1918, p. 46.

SOME CAUSES OF BOILER-TUBE FAILURES, R. Cederblom. Power, vol. 48, no. 2, July 9, 1918, pp. 43-46, 4 figs. Theory advanced that failure of tubes through blistering is due to steam formation in the tube preventing the water from sweeping the tube surface and keeping it cool. How to minimize the trouble; influence of baffling on steam generated per square foot of tube.

CAUSES OF VACUUM TROUBLE, L. F. Forseille. Power, vol. 47, no. 26, June 25, 1918, p. 909, 1 fig. An analysis of trouble experienced in the maintenance of a normal vacuum on a 10,000-kva. turbine unit equipped with a jet type of condenser.

MAIN AND AUXILIARY STEAM PIPING, Ralph W. Propert. The Journal of the American Society of Marine Draftsmen, vol. 5, no. 1, April 1918, pp. 9-11.

SOOT BLOWERS FOR HORIZONTAL WATER-TUBE BOILERS. Power, vol. 48, no. 1, July 2, 1918, pp. 2-7, 19 figs. An extensive discussion of the subject of soot blowers with special reference to the different types of mechanical blowers on the market and their application to the various boilers in use.

GASKETS FOR STEAM-PIPE LINES, Zeno Schultes. Power, vol. 48, no. 1, July 2, 1918, pp. 8-10, 4 figs. General discussion of the subject of packing for steam pipe lines. The author claims that flanged pipe joints are particularly apt to leak and explains it by the presence of rough flange faces, large bolt holes and holes spaced too far apart.

VARIA

AMERICAN CHEMISTS' DEFENSIVE MEASURES AGAINST GAS ATTACKS IN FRANCE, Robert K. Tomlin, Jr. Metallurgical and Chemical Engineering, vol. 18, no. 12, June 15, 1918, pp. 636-639, 3 figs.

HANDLING MATERIALS AT HOG ISLAND, H. Cole Estep. The Marine Review, vol. 48, no. 7, July 1918, pp. 277-279, 313, 4 figs.

EVOLUTIONARY BUSINESS PRINCIPLES, L. P. Alford. Industrial Management, vol. 56, no. 1, July 1918, pp. 8-9.

VESTIBULE SCHOOLS FOR THE UNSKILLED, H. E. Miles. Industrial Management, vol. 56, no. 1, July 1918, pp. 10-12.

BOXING MACHINERY TO PREVENT DAMAGE, Luther D. Burlingame. Industrial Management, vol. 56, no. 1, July 1918, pp. 27-33, 18 figs.

TANKS FOR WATER SUPPLY, Charles L. Hubbard, National Engineer, vol. 22, no. 7, July 1918, pp. 288-295, 18 figs., 1 table.

ARMY LEAD IN WASTE PREVENTION AND UTILIZATION. Engineering News-Record, vol. 81, no. 1, July 4, 1918, pp. 25-26, 1 table.

L'INDUSTRIE DU CHAPEAU DE PAILLE EN LORRAINE. Société Industrielle de l' Est, Bulletin no. 138, May 1918, pp. 4-12. The straw-hat industry in Lorraine.

YOUNGSTOWN SHEET AND TUBE TANDEM PLATE MILL. The Iron Age, vol. 101, no. 26, June 27, 1918, pp. 1660-1663, 6 figs. Description of continuous slab-heating furnaces and new type of plate turnovers. Capacity, 15,000 tons per month.

INTERMEDIATE RATE FINE-SAND WATER FILTER OPERATES UNDER VACUUM. Engineering News-Record, vol. 80, no. 26, June 27, 1918, pp. 1230-1232, 4 figs. Silty water after a 75-mile journey through

irrigating [illegible] is clarified without chemical treatment to the extent of 3 million gallons daily.

Engineering Education as Applied to Naval Architecture and Marine Engineering, H. A. Everett. International Marine Engineering, vol. 23, no. 6, June 1918, pp. 337-342. From an address before the Delaware River Branch of the American Society of Marine Draftsmen, Feb. 1918.

Training Engineer Officers for the Army at Camp Lee, Frank C. Wight. Engineering News-Record, vol. 81, no. 1, July 4, 1918, pp. 12-15, 10 figs.

Compulsory Cooperation of Central Station and Isolated Plant, S. R. Sague. Power, vol. 47, no. 25, June 18, 1918, pp. 870-872. Correspondence with city officials of Cleveland, O., the Fuel Administration and others concerning the advisability of enforced coöperation of public-service and privately owned plants, so as to avoid duplication of distribution systems and prevent waste of coal.

Early Attempts at Submarine Building, H. H. Manchester. American Machinist, vol. 48, no. 26, June 27, 1918, pp. 1081-1085, 10 figs. Attempts by former generations to devise submarine boats dating from 390-1800 A. D.

The Laws Guarding Machinery, Chesla C. Sherlock. American Machinist, vol. 49, no. 2, July 11, 1918, pp. 76-78.

The Lyons Fair. American Machinist, vol. 49, no. 2, July 11, 1918, pp. 68-70, 2 figs. Delayed correspondence dealing with the annual industrial exposition at Lyons, France.

War as a Test of Efficiency, Edward H. Hurley. American Machinist, vol. 49, no. 1, July 4, 1918, pp. 11-12.

Changes in American Machine-Tool Exports, L. W. Schmidt. American Machinist, vol. 49, no. 1, July 4, 1918, pp. 9-11. Changes in the industrial condition of our allies which must be taken into account in planning after-war business.

Factory Moving, L. J. Hengesbach. Machinery, vol. 24, no. 11, July 1918, pp. 999-1002, 5 figs. Methods of efficiently solving the problems arising when moving machinery into a new factory.

Training Women for the Drawing Room, Howard W. Dunbar and W. E. Freeland. The Iron Age, vol. 102, no. 1, July 4, 1918, pp. 1-5, 2 figs. Description of the successful teaching system employed by the Norton Grinding Co., and of the results secured.

LIBRARY NOTES AND BOOK REVIEWS

Articles of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

BOOK NOTES

American Lubricants. From the Standpoint of the Consumer. By L. B. Lockhart. The Chemical Publishing Co., Easton, Pa., 1918. Cloth, 6x9 in., 236 pp., 13 illus., 44 tables. $2.

The purpose of this book is to aid the user of lubricants in the intelligent selection of oils and greases by giving facts and figures of value and excluding all irrelevant matters.

American Railway Accounting. A Commentary by Henry C. Adams. Henry Holt & Co., New York, 1918. Cloth, 5x8 in., 465 pp. $3.

Discusses the standard system of railway accounts promulgated for and used by American railways and is intended to explain the accepted rules to students of accounting and practical accountants.

Automobile Construction and Repair. A Practical Guide to the Design, Construction, and Repair of Automobile Mechanisms. By Morris A. Hall. American Technical Society, Chicago, 1918. Flexible leather, 711 pp., 6x8 in., 568 illus., 4 pl., 4 tables. $2.50.

Intended for mechanics engaged in automobile construction and repair. Describes the construction of the standard types of transmission, clutches, valves, etc., and gives methods for repairing the troubles that occur in operation.

Train Operation. A Treatise on Train Rules, Train Orders, Change of Time Table, Automatic Block Signals, Interlocking, Examination Questions and Answers. By William Nichols. Le Grand Brown, Rochester, N. Y., 1916. Flexible leather, 340 pp., 55 pl., $2.50. (flexible cloth $2.)

An interpretation and amplification of the Rulings of the American Railway Association issued prior to November, 1915, and of the Standard Train Rules and other practices which have been found necessary in handling trains. Based on the author's experience as chairman of the Board of Examiners, Southern Pacific Co., but does not apply to any particular railroad.

The Fighting Engineers. The Minute Men of Our Industrial Army. By Francis A. Collins. The Century Co., New York, 1918. Cloth, 5x8 in., 220 pp., 31 pl. $1.30.

A popular account of the work of the American engineering regiments in France and America.

The Financing of Public Service Corporations. By Milton B. Ignatius. The Ronald Press Company, New York, 1918. Cloth, 6x9 in., 508 pp. $5.

This volume presents a comprehensive discussion of all the important aspects of public-service-corporation financing from the inception of the enterprise to the expenditure of the proceeds. Intended for corporation officials, public officers, bankers and brokers. Based on the work of the Public Service Commission of the Second District of New York.

Heating and Ventilation. By John R. Allen and J. H. Walker. First edition. McGraw-Hill Book Company, Inc., New York, 1918. Cloth, 6x9 in., 305 pp., 174 illus., 76 tables. $3.

Intended for use as a textbook in schools of engineering and architecture, and as a handbook by practising engineers.

Hiring the Worker. By Roy Willmarth Kelly. The Engineering Magazine Co., New York, 1918. Cloth, 6x9 in., 245 pp., 8 pl., 66 forms, 5 charts, 2 folded, 2 tables. $2.

A summary of the efforts of many firms to solve the problems of employment. Describes the theories and policies which have been tested, suggests the possibilities of employment management and attempts to point out the profitable avenues of advancement.

A History of Chemistry. By F. J. Moore. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6x8 in., 292 pp., 6 illus., 12 pl., 37 por., 8 diag., 5 tables. $2.50.

This volume is based on a course of lectures given to the senior students of chemistry in the Massachusetts Institute of Technology and is intended to provide a concise account of those facts and influences which have made the science what it is today. Suitable for mature students.

An Introduction to the Chemistry of Plant Products. By Paul Haas and T. G. Hill. Second edition. Longmans, Green and Co., New York, 1917. Cloth, 6x9 in., 411 pp., 5 illus. $3.50.

This work is an attempt to provide botanists with an account of the chemical and biological significance of the more important substances occurring in plants. The present edition has been revised as a whole and the section on plant pigments has been rewritten.

Modern Inorganic Chemistry. By J. W. Mellor. New edition. Longmans, Green and Co., New York, 1917. Cloth, 6x8 in., 910 pp., 334 illus., 64 tables. $2.50.

A general course in chemistry intended to develop skill in observation and experiment, memory and knowledge of relevant facts, ability to reason and think in a logical, systematic way, to cultivate the imagination and to develop a critical and impartial judgment.

Modern Locomotive Valve and Valve Gears. By Charles L. McShane. Griffin & Winters, Chicago, 1918. Cloth, 5x8 in., 339 pp., 113 illus., 1 folded pl. $2.50.

A practical discussion of the principles, construction and operation of the valves and valve gears of modern locomotives. Written in simple, non-mathematical language.

Northwest Mines Handbook. A Reference Work of the Mining Industry of Idaho, Washington, British Columbia, Western Montana and Oregon. By Sidney Norman. Vol. 1. Published by author, Spokane, 1918. Cloth, 6x10 in., 366 pp. (advertising pages included), 28 illus., 9 por., 2 maps, 1 folded, 13 tables. $5.

Covers the mining enterprises which surround Spokane. Contains general descriptive articles on mining and geology of each state, statistics of production, gives lists of the mines and mining corporations, showing capital stock, property and development.

Over the Drawing Board. A Draftsmen's Hand Book. By Ben J. Lubschez. Journal of the American Institute of Architects, Washington, 1918. Cloth, 5x7 in., 131 pp., 22 illus., 9 pl. $2.

Contents: Introductory, Drafting Room, Equipment, Instruments, Mounting of Paper and Drawings, Tracing Paper and Tracing Cloth, Geometrical Short-cuts, Lettering, Titling, Numbering, Working Drawings, Indications, Lines, Sketches, Exhibition Drawings, Water Colors, Perspective, Filing of Drawings and Plates, Photography, the Reproductive Processes, Photo-Engraving, Etching, Wood Engraving, Lithography.

From his experience and observation, the author has selected convenient methods and short-cuts for draftsmen.

Popular Oil Geology. By Victor Ziegler. C. H. Merrifield, Golden, Col., 1918. Flexible cloth, 5x7 in., 149 pp., 62 illus., 1 pl. $2.50.

An exposition of the fundamental principles of oil geology, intended for men without technical training who are interested in the subject.

Regulation of Railways. Including a Discussion of Government Ownership Versus Government Control. By Samuel O. Dunn. D. Appleton and Co., New York, 1918. Cloth, 5x8 in., 354 pp., 5 tab. $1.75.

Contents: What is the Matter with Railway Regulation? Functions of Government in Relation to Railways, Commission versus Legislative Regulation, Federal versus State Regulation, Regulation of Rates, Valuation in Relation to Regulation of Rates and Securities, Regulation of Securities, Regulation of Railway Operation, Peaceful Settlement of Labor Disputes or Strikes? Government Regulation versus Government Ownership, Some Practical Phases of Government Ownership, The Failure of Government Ownership in Canada.

A general presentation of the methods that have been advocated and of the actual effects of rate regulation.

Rubber. Its Production, Chemistry and Synthesis in the Light of Recent Research. A Practical Handbook for the Use of Rubber Cultivators, Chemists, Economists and Others. By A. Dubosc and Dr. A. Luttringer. English Edition by Edward W. Lewis. J. B. Lippincott Co., Philadelphia, 1918. Cloth, 6x9 in., 383 pp., 51 tables. $6.50.

The authors have collected into a single volume all the scattered writings relating to the cultivation or the modern chemistry of rubber, with the addition of their own observations on these subjects. Much attention is given to the various proposed processes for the synthesis of rubber.

Scientific Management. A History and Criticism. By Horace Bookwalter Drury. Second edition, revised. Studies in History, Economics and Public Law; Edited by the Faculty of Political Science of Columbia University. Vol. 65, No. 2. Whole Number 157. Columbia University, New York, 1918. Paper, 6x10 in., 251 pp. $2.

A history of the origins and development of scientific management, with a critical review of its important aspects. Brief biographies of the leaders in the movement are given, and its relation to labor is discussed. The present edition has been largely extended and revised. The statements have been brought down to date, and the conclusions have been rewritten in a number of cases.

Strength of Materials. A Comprehensive Presentation of Scientific Methods of Locating and Determining Stresses and Calculating the Required Strength and Dimensions of Building Materials. By Edward R. Maurer. American Technical Society, Chicago, 1918. Cloth, 5x8 in., 126 pp., 2 pl., 7 tables. $1.

An elementary presentation of the subject, in which the use of higher mathematics has been avoided.

Standard Wiring for Electric Light and Power. As adopted by The Fire Underwriters of the United States, in Accordance with This Year's Edition of the National Electrical Code, with Explanations, Illustrations and Tables Necessary for Outside and Inside Wiring and Construction for All Systems, Together with a Special Section on House Wiring. By H. C. Cushing, Jr. H. J. Cushing, Jr., New York (copyright, 1918). Flexible cloth, 4x7 in., 360 pp. (advertising pages included), 4 illus., 21 diag., 37 tables.

This edition of the essential rules and requirements for safe and efficient wiring and construction for electric heat, light and power follows the plan adopted in former editions, but has been revised to meet present requirements.

A Text-Book of Inorganic Chemistry. Edited by J. Newton Friend. Vol. 5: Carbon and Its Allies, by R. M. Caven. J. B. Lippincott Co., Philadelphia, 1917. Cloth, 6x9 in., 468 pp., 15 illus., 70 tables, 1 folded, 1 chart.

Contents: Introductory, Carbon and its Compounds, Silicon and its Compounds, Titanium and its Compounds, Zirconium and its Compounds, Thorium and its Compounds, Germanium and its Compounds, Tin and its Compounds, Lead and its Compounds.

The aim of this series is to provide a comprehensive textbook of inorganic chemistry, sufficiently complete for ordinary purposes, and supplied with numerous references to the leading works and memoirs.

Tire Making and Merchandising. A Book of Facts Concerning Manufacturing Processes, Illustrating the Principal Tire Types, Rims and Non-Skid Treads, with Chapters on Rubber and Other Factors Governing Tire Costs, Present and Future Trend of the Market, Merchandising for Profit, Dividends from Service, Marketing Methods and Sales Campaigns, Tire Equipment of All Pleasure and Commercial Cars from 1913 to Present Date, and a Dealers' Dictionary of Terms. By F. R. Goodell. U. P. C. Book Company, New York, 1918. Flexible cloth, 5x8 in., 222 pp., 42 illus., 6 tables, maps, 7 diag. $2.

A compact summary of information on tire manufacture, marketing and merchandising, designed especially for those engaged in tire business.

Topography and Strategy in the War. By Douglas Wilson Johnson. Henry Holt and Co., New York, 1917. Cloth, 6x9 in., 211 pp., 33 pl., 18 maps. $1.75.

The author's objects have been to emphasize the effect played by land forms in plans of campaign and movements of armies in the great war, and to place before the reader a picture of each theater of war that will enable him to follow with intelligence the movements of the troops.

Wooden Shipbuilding. A Comprehensive Manual for Wooden Shipbuilders, to Which is Added a Masting and Rigging Guide. Compiled by W. J. Thompson. A. C. McClurg & Co., Chicago, 1918. Flexible cloth, 5x7 in., 202 pp., 2 tables. $2.50.

Contents: Wooden Ships, Masts and Rigging, Methods of Masting, Tables of Rigging. A book of pocket size, compiled from standard authorities. Chiefly intended as a glossary of the parts of ships and their rigging, with brief descriptions of the methods of construction, arranged in dictionary form.

Electric Furnaces in the Iron and Steel Industry. By W. Rodenhauser, J. Schoenawa and C. H. Vom Baur. Translated from the original by the latter and now completely rewritten. Second edition. John Wiley & Sons, Inc., New York, 1917. Cloth, 6x9 in., 429 pp., 134 illus., 2 pl., 24 tables. $3.75.

A review of the electrical furnaces used in iron smelting, and of the processes employed. The present edition contains minor revisions covering certain changes since 1913.

Tycos Mineral Oil Tables. Taylor Instrument Companies, Rochester, N. Y., 1918. First edition. Cloth, 4½x6½ in., 204 pp. $1.

A useful and handy collection of gravity and temperature tables for mineral oils—from determinations of the Bureau of Standards, together with other tables for general testing and refinery practice, including viscosity, water density, steam, ammonia and humidity tables, as well as tables for the conversion of weights and measures, and various physical and chemical tables. The book also contains instructions for testing oils.

Correction.—The price of A. N. Goldsmith's Radio Telephony is $2 instead of $1.25, as stated in the June issue.

ACCESSIONS TO THE LIBRARY

ALUMINUM. Its history, occurrence, properties, metallurgy and applications, including its alloys. Edition 2. By Joseph W. Richards. *Philadelphia, 1890.* Gift.

ALUMINUM AND ITS CONGENERS, including the rare earth metals. By H. F. V. Little. Vol. IV of Text-book of Inorganic Chemistry. *London, 1917.* Purchase.

THE EFFECT UPON FUEL ECONOMY OF DIFFERENT ARRANGEMENTS OF BAFFLES IN BOILER TUBES

By Lieut. William G. Eager,[1] Philadelphia, Pa.

When it is considered that the cost of fuel is invariably from forty to sixty per cent of the operating cost of producing power and that even in a small plant this cost runs to many thousand dollars a year, it is surprising that so little time is given by operators to investigating the effect upon fuel economy and boiler capacity of varying the paths of the gases between the combustion chamber and the uptake.

Considerable thought seems to be given to the design of the boiler shell, tubes and accessories to make them more nearly perfect theoretically and mechanically. An arbitrary relation is taken between heating surface and grate area based upon years of experience, and much ingenuity is used in the development and application of different types of mechanical stokers and other labor-saving appliances. There seems to be, however, among some boiler makers and operators an indifference in the matter of investigating the actual results obtained by varying the location of the baffles in the banks of boiler tubes.

Upon this phase of boiler practice depends to no small extent the ultimate economy of the boiler. If the gases pass through the banks of tubes in too direct a course, they carry with them up the stack an unnecessary amount of valuable heat. On the other hand, if the arrangement of baffles in the tubes is such as to restrict unduly the passage of the gases, the boiler may evaporate water economically but it will not readily respond to unusual demands on its capacity.

Again, the baffles may be so arranged as to form pockets of inactive gases, which are excellent non-conductors and which will tend to cut down the effective heating area. This would lower both the efficiency and capacity of the boiler.

Object of Tests

With these facts in view, a series of tests was made upon three similar boilers of the Heine type to determine the arrangement of baffles for this type of boiler which would give the best evaporation in pounds of water from and at 212 deg. fahr. per pound of coal, and at the same time meet the requirements of full capacity and a moderate superheat temperature.

These tests were made under commercial operating conditions at the combination ice and electric plant of the Valdosta (Ga.) Lighting Company and extended over a period of six and one-half weeks, beginning March 10, 1913. No records of previous investigations along this definite line and no references dealing with this specific phase of boiler practice were available. While it was not possible to introduce such refinements as are obtained in laboratory work, it is believed that the tests conducted under these normal and fairly uniform operating conditions have satisfactorily brought out the valuable features of the matter under investigation. The questions of the effect of baffling on draft, combustion, circulation and scale forming are of interest and importance, but these are problems which could each be made the major subject of an extended investigation. It is not intended in this discussion to attempt to differentiate between the effects produced by each of these factors, but to accept the effects as a whole as reflected in the final results.

Had a CO_2 recorder been available these records would prove of value and importance in that they would indicate what degree of uniformity of combustion was obtained in the various cases. Such an instrument, however, was not at hand, and, with a view to obtaining a comparison which would indicate any wide variation in the method of firing, tests were conducted on each of the three boilers, using the two arrangements of baffles which showed best results.

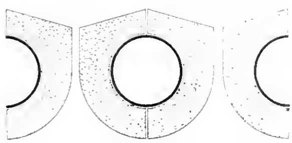

Fig. 1

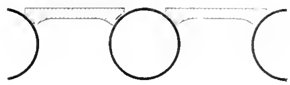

Fig. 2

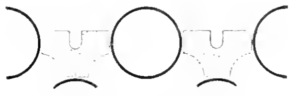

Figs. 1-3 Types of Baffle Tile Used in Boiler Tests

Note.—Tile in Fig. 3 falls away from tubes at top and closes passage between tubes.

Principles and Methods Employed in the Investigation

The problem involved in this work was fundamentally the choosing of that location of the baffles which would enable the heating surface of the boiler to extract the greatest amount of heat from the coal burned without impairing the capacity of the boiler, and this brought up for consideration several important points and principles. First of all, an encircling tile shown in Fig. 1 was used on the lower bank of tubes. This baffle remained the same in each test, and it is interesting to note that it offered a hot surface against which the unburned gases might impinge, thus burning the volatile matter and carbon particles more completely than as if they had been allowed to strike the cold surface of the tubes. Secondly, this encircling tile saved the lower banks of tubes by protecting them from wide and sudden temperature variations and the intense heat over the bridge wall.

The orifice between these baffles on the lower bank of tubes and the back water leg must be large enough not to restrict the flow of the gases and yet close enough to the rear water leg to force the gases well back in order to take full advantage of the large heating area of these tubes, which would be lost if the gases were cut off too soon. The middle course of baffles, where one is used, must be placed with this latter thought in

[1] Assoc.-Mem.Am.Soc.M.E. Formerly Gen. Mgr. Valdosta (Ga.) Lighting Co.; now Lieut. (Sr. G.) U. S. N. R. F., Asst. Production Mgr. in Charge of Field Work, Philadelphia District.

Abstract of a paper presented at a meeting of the Atlanta Section of The American Society of Mechanical Engineers, April 9, 1918.

mind, and in addition it must be remembered that the falling temperature of these gases at practically constant pressure gives a corresponding reduction in volume, and for this reason this course of baffles should be pushed nearer to the front water leg than the lower baffle is to the rear water leg. This type of baffle is shown in Fig. 2. If the split baffle is used, that is, if the baffle does not extend to either water leg, it should be installed in such a way as to split evenly the gases, as the heating surfaces either way are practically the same. Moreover, equal care must be taken not to obstruct the gases here.

Another item to be considered in connection with this baffle is that its position will affect the temperature of superheated steam to a considerable extent, as will be shown. The principles regarding the reduction in volumes and the undue restriction of gases also apply to the top course of baffles. This type is shown in Fig. 3. It must be borne in mind that the heating area under the drums is much less than that available in the banks of tubes above the middle baffle, and also that if the gases are permitted to do so, they will rise under the drums and move along it to the uptake. If these gases are therefore to be split at this point, they should be divided roughly in the ratio of the effective heating area under the drums and that available in the tubes. In this connection, however, it is well to note that the gases in the banks of tubes will tend to creep along the top banks to some extent, and that these banks will consequently do more than their share of the work. Care must also be taken in the placing of baffles to see that they are not so located as to prevent the proper blowing of the soot from around the tubes.

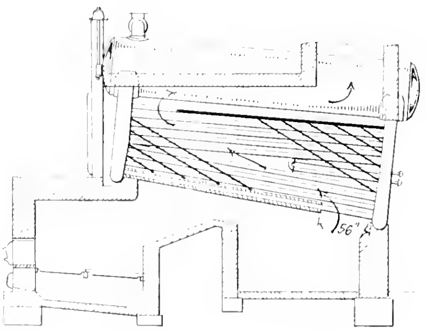

Fig. 4 Location of Baffles and Path of Gases in Boiler, Case A

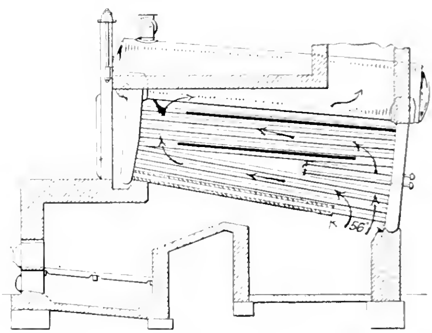

Fig. 5 Location of Baffles and Path of Gases in Boiler, Case B

It is of the greatest importance that all air leaks be stopped and that the stack damper be always in good operating shape and intelligently used. No matter what form of baffling is used, it is absolutely necessary, from the standpoint of economy, that there be no holes or missing baffles in any course. Such a condition will cause the gases to short-circuit, and will be indicated by decreased evaporation per pound of coal and higher stack temperature.

All these tests were carried out according to the code of The American Society of Mechanical Engineers. The alternate method of starting and stopping was used. Each test was from 58 to 120 hours' duration. Observations were made hourly. With the boilers cold, readings were taken on the gage glass and the water meter simultaneously as the boiler was filled to determine the volume of water admitted for each fraction of an inch on the gage glass. This was done to determine the amount of water blown off. The coal used was Crane Creek No. 1, run of mine, from Colmar, Kentucky. It was dumped in one large pile and was taken from different points in this pile as required. The term "combustible" is used to designate coal dry and free from ash and refuse. This was determined by deducting from the coal as weighed the percentage by weight of moisture, found by drying it artificially, plus the weight of ashes and refuse taken from the ashpits. The feedwater was treated with soda ash and tri-sodic phosphate before reaching boilers, and was fed as uniformly as possible under the varying operating conditions. Water was weighed at average feedwater temperatures.

A thin, fast fire was invariably carried, and the load, which consisted of steam turbines used for generating electricity and an engine driving an ammonia compressor, was quite variable at different times of the day and night, due to the variation of the electric load and the occasional shutting down of the ice machine. To bring out clearly the extent of this variation, figures have been compiled which indicate the ratio of the average boiler horsepower developed during the whole test and the average horsepower developed over the hourly period during which the total output for the hour was a maximum.

Description of Boilers

The tests were made upon three similar boilers of the Heine return tubular type, made by the Casey Hedges Company. They had a heating area of 5000 sq. ft. and a grate area of $86^{3}/_{4}$ sq. ft., giving a ratio of 56 to 1 between heating surface and grate area. The rated horsepower was 500. The boilers were equipped with Dutch ovens and were hand-fired. No. 1 had been in use but a few weeks, while No. 2 and No. 3 had been in service for about a year. No. 3 was equipped with Thomas elliptic grate bars, and Nos. 1 and 2 with the ordinary type of herringbone bars. The boilers were all equipped with Foster superheaters and Bayer soot blowers, and were thoroughly cleaned before beginning the tests. No. 1 was not insulated. The other two had a covering of 1½ in. of asbestos cement over settings and drums.

The apparatus used consisted of Howe scales, a Worthington turbine feedwater meter of the hot-water type, a Bristol recording steam gage, indicating gages, stack pyrometer and thermometers in feedwater line and steam lines. All instruments were checked and calibrated.

Arrangement of Baffles

Four different arrangements of baffles were used which are designated as cases *A*, *B*, *C* and *D*, shown in Figs. 4, 5, 6 and 7, respectively. Case *A* indicates the maker's arrangement of baffles in boilers Nos. 2 and 3. This consisted of a set of encircling tile (see Fig. 1 for detail of tile) around the lower course of tubes extending from the front water leg to within 56 in. of the back water leg and a set of special V-tile (see Fig. 3) resting upon the top course of tubes and extending from the rear water leg to within 42 in. of the front water leg.

The course of the gases would therefore be from the lower corner at back of boiler upward, then under the drums and out. Fig. 4 shows the arrangement of baffles and the course of these gases. Low evaporation per pound of coal indicated that the gases were passing through the banks of tubes too quickly, and an observation of the condition of the tubes led to the belief that the shaded area in Fig. 4 was in a practically inactive state.

The indications were that dead-air pockets were formed at these places, which were quite effectually preventing these parts of the tubes from getting their proportion of the heat and, therefore, from doing their proportion of the work. With a view to modifying this in such a way as to overcome this fault, and to distribute the heat more evenly over the whole length of the tubes, a split baffle was used over the lower course of the top section of tubes. This method is called Case *B* and is indicated in Fig. 5. The baffle in this case was of cast-iron tile and rested upon adjoining tubes. (See Fig. 2 for section of baffles.) The baffles were placed from within 40 in. of the front water leg to within 40 in. of the rear water leg. As far as the volume of gases at this point is concerned, this baffle could well have been extended closer to each water leg, but it was thought best on account of the position of the superheater in one path and the sudden change of direction of gases in the other path to locate it in this way. It was expected that an increase in the temperature of the superheated steam would result from this method because it permitted a part of the gases to pass through the whole of the superheater instead of merely crossing one end of it.

Fig. 6 indicates the maker's arrangement of baffles in boiler No. 1, which was new when tested. This is designated as Case *C*. It will be noted that the lower baffle is the same as in previous cases, that the middle baffle is moved 48 in. from the front water leg and is extended entirely to the rear water leg, and that the top baffle is split and extended to within 42 in. of each water leg, with a vertical wall around the drums and midway the baffle, which forces the gases after striking the drums to return and pass through the upper banks of tubes and then out. It was found that this arrangement reduced the capacity of the boiler so as to cause a failure of steam over the peak load. There was apparently no reason for this unless it was that an eddy or swirl was set up at *E* (see Fig. 6), due to the gases returning to the tubes after striking the drum. Such a swirl would, no doubt, seriously obstruct the passage of gases at this point, and there seems no other logical reason for the behavior of this boiler.

Case *D*, shown in Fig. 7, is a modification of this arrangement with a view to overcoming the difficulty apparently arising from this cause. With the lower and middle baffles the same as in Case *C*, the top baffle is continued to within 8 in. of the front water leg and the vertical wall around the drums is removed. This, it will be seen, causes the gases to divide, the main portion of them passing through the tubes and the smaller portion through the 8-in. orifice, under the drums and out.

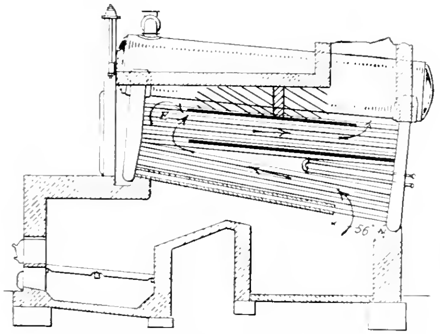

Fig. 6 Location of Baffles and Path of Gases in Boiler, Case *C*

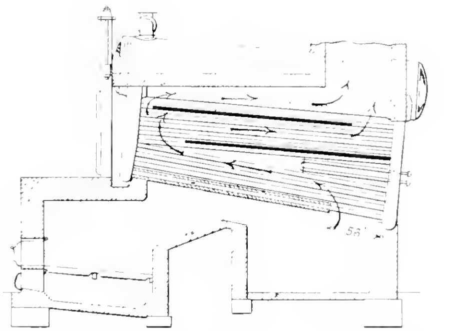

Fig. 7 Location of Baffles and Path of Gases in Boiler, Case *D*

Conduct of Tests

It was the original plan to have each test cover a period of 120 hours, and the first one was carried over this period. The second was begun with this idea in view, but because of the development of weakness in one of the tubes this test was closed at the end of 58 hours. On account of operating difficulties, it was decided to make the remaining tests of 58 hours' duration. Such important observations as weights of coal and water were checked and a record of all unusual conditions was kept in the daily log sheet. Each test was computed as soon as it was finished, and the data thus obtained were used in determining the arrangement of baffles in the next test and the desirability of checking that method on the other boilers. The principles and details of the method have been fully described. The indicating steam gages were checked against the recording gage from time to time. Care was taken to avoid inequalities in the coal, which was taken from different points in a large pile in rotation. Unusual care was taken in the starting and stopping of tests to see that the test conditions were satisfied.

The *A* test was not run on boiler No. 1 because the evaporation obtained in the *B* test on the other boilers was obviously better and because the results obtained from boilers Nos. 2 and 3 were in line when the relative horsepower developed and the

varying conditions were taken into consideration. The *C* test was not run on boilers Nos. 2 and 3 because the test on boiler No. 1 indicated that this arrangement of baffles would not be satisfactory from the operating standpoint on account of the cutting down of capacity. The choice seemed to lie between the *B* and *D* methods of baffling, and these tests were respectively made on each boiler.

Computations and Results

As the calculations are of minor importance and are not out of the ordinary, only an outline of the method followed will be given. A five-place table of factors of evaporation for different pressures and temperatures of feedwater, corrected in each instance for superheat, was compiled from the seventh edition of Peabody's Tables, and used to determine the equivalent evaporation from and at 212 deg. The figures for weight of water at various temperatures were determined by weighing the water at these temperatures. The results of the calculations are given in Table 1.

load conditions of a central station are varying, and that a fireman who is accustomed to the way the load comes on during the day is at a disadvantage on the night turn until he becomes accustomed to the load as it comes on during the shift. Care was taken to avoid these variations as far as possible, but because of their occurrence tests were conducted upon three boilers instead of upon one only. The results appear logical with few exceptions.

Test under case *A* on boiler No. 3 showed a much lower evaporation than the corresponding test on boiler No. 2. This was no doubt due to the lower average horsepower developed by boiler No. 3, which was only 342, as against 519 for boiler No. 2. All the tests on boiler No. 1 appeared abnormally low for a new, clean boiler, and this was probably due to the fact that while both the other boilers were well protected with asbestos covering, the drums and the setting of boiler No. 1 were exposed. Boiler No. 3 was the only one that did not show a decided advantage in evaporation for the *D* arrangement of baffles over the *B* arrangement. It will be noted, however, that the average horsepower developed in the *B* test was 535

TABLE 1 DATA OBTAINED IN BOILER TESTS

	A Test		*B* Test			*C* Test	*D* Test		
	Boiler No. 2	Boiler No. 3	Boiler No. 1	Boiler No. 2	Boiler No. 3	Boiler No. 1	Boiler No. 1	Boiler No. 2	Boiler No. 3

Average steam pressure in boiler during test, lb. per sq in. gage.	156	153	155	155	157	156	158	157	159

Accuracy of Tests, Methods and Results

While the instruments used were calibrated and checked, it would have made very little difference as far as the comparative value of the baffling was concerned as long as the same variation occurred in each test. The greatest inaccuracy which was likely to occur was in starting and stopping, and in this unusual care was taken. As 58 hours was the shortest period of any test, such an inaccuracy would be minimized in the final result, and it is safe to assume that the variation due to this cause alone would not have amounted to over one-half of one per cent.

It would appear that the personal equation in firing of boilers would be the most likely source of comparative variation. A fireman's physical condition will affect his firing, and a change of men might account for a rather wide variation. It has been observed that a remarkable increase in coal consumption is to be noted when firemen change from the day to the night shift, and vice versa. This is due to the fact that the

as against 519 in the *D* test, so that the gain, while less than in the other cases, is more marked than a glance at the figures would indicate. In the other two cases, although the horsepower developed in the *B* test was higher than in the *D* test and better economy would be expected on account of the increased horsepower, the *D* arrangement of baffles shows to advantage in economy.

Discussion of Results

Fig. 8 indicates graphically the results obtained in equivalent evaporation from and at 212 deg. per pound of coal and per pound of combustible in tests *A*, *B* and *D*. Case *C* is not plotted as this was run only on boiler No. 1, because with this arrangement of baffles No. 1 developed a weakness in overload capacity and, while the average horsepower developed was high, it was unable to carry the peak load. The objections are, first, an apparent interference with the passage of the gases

at E, Fig. 6, due to the gases returning upon themselves, and, secondly, an area heated only by convection, which for all practical purposes may be considered a dead area, between the top baffle and the drum and indicated by the shaded area in Fig. 6.

The full lines in Fig. 8 indicate the equivalent evaporation in pounds of water from and at 212 deg. per pound of coal, and the dotted lines the equivalent evaporation per pound of combustible. An interesting feature in connection with these curves is that the full-line curve of boiler No. 3 crosses that of No. 2 twice, whereas when the available combustible matter, which varies with the quality and firing of the coal, is taken into consideration, as indicated by the dotted lines, all three points of No. 3 fall below the corresponding points of No. 2.

There is a noticeable improvement in case B over case A and case D over case B in each instance. The low point No. 3 reaches in case A is without doubt due to the low horsepower developed and the wide variation in load. The horsepower was 342 against 535 for the B test and 519 for the D test. That is, while the average horsepower developed during tests B and D was slightly in excess of the boiler rating, it was in the A test 33.6 per cent under the rated capacity. The load factor, as this term is defined in Table 1, was 0.50 as against 0.69 in each of the other tests on this boiler. The low evaporation in the B and D tests on boiler No. 1 can probably be practically accounted for when it is noted that this was the only boiler not covered with asbestos.

The low evaporation obtained in the B test on this boiler, together with the high stack temperature and the unusually high superheat temperature, seem to be due to a partial short-circuit in the top baffle (see Fig. 5) near the rear water leg. This baffle was not put in permanently, and the poor fit of the baffle tile at the rear water leg would cause the gases to rush through the superheater and part of them directly up the stack, thus raising the superheat and stack temperatures and impairing the efficiency.

The results which placed the point on the curves for the B test on boiler No. 3 nearest to the curves of No. 2 were obtained when this boiler was developing an average horsepower 11 per cent in excess of that developed by No. 2 in the similar test. When the relative horsepower and the abnormal external influences are taken into consideration, it will be seen that the results obtained on the three boilers corroborate in a striking and conclusive manner the relative value of the three forms of baffling.

Fig. 9 indicates in full lines the stack temperature noted for each arrangement of baffles and in dotted lines the degrees of superheat developed in each case. It will be noted that the curves for stack temperature and for superheat in the cases of boilers Nos. 2 and 3 are almost concentric, and that, while No. 3 developed the highest stack temperature, No. 2 ran above it in superheat temperature. The unusually low stack temperature in the case of boiler No. 2 is undoubtedly due to the fact that it was impossible to locate the pyrometer in the breeching of this boiler in such a way as to avoid the cooling due to leakage in the dampers of the other two boilers. It was possible in No. 1 and No. 3, however, to locate the pyrometer in such a way as to avoid this difficulty.

As has been mentioned before, in the B test on boiler No. 1 the top baffle was not carried tight against the rear water leg, as this was put in temporarily. This would easily explain the unusually high superheat temperature for this test. The superheat temperature developed was in all instances higher in case B than in any of the other cases. Reference to the diagrams showing the location of baffles will make this clear, as it will be seen that the larger part of the hot gases pass through the superheater.

Conclusions as to Completeness of Tests

The D arrangement of baffles not only shows in each test an unquestionable superiority over the other arrangements from the standpoint of efficient evaporation, but it meets the other requirements for a thoroughly satisfactory commercial arrangement of baffles. It develops a low superheat temperature, which, as long as the steam is thoroughly dry, is considered of advantage in the case of the apparatus in use; it does away with inactive and dead air pockets, which is immediately apparent from an examination of Figs. 6 and 7; it presents

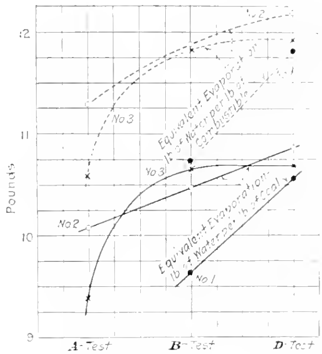

FIG. 8 CURVES SHOWING EQUIVALENT EVAPORATION PER LB. OF COAL AND PER LB. OF COMBUSTIBLE, CASES A, B, D, BOILERS NOS. 1, 2 AND 3

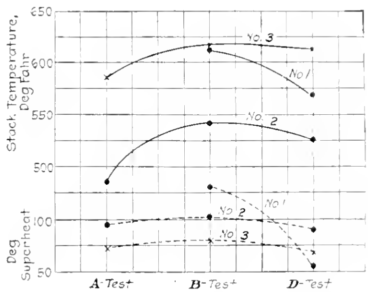

FIG. 9 CURVES SHOWING STACK AND SUPERHEAT TEMPERATURES IN DEG. FAHR., CASES A, B, D, BOILERS NOS. 1, 2 AND 3

an arrangement of baffles which may be easily blown by the soot blowers, and with this arrangement of baffles the boiler stands up satisfactorily to considerable overload.

Recommendations as to Further Research

While the principles involved in these tests and the results brought out by them will be true to a greater or less degree in the case of all boilers of similar design, it would probably be well before adopting a certain type of baffling in any boiler to conduct a series of tests to determine such details as the exact distance from water legs to baffles and the effect of various arrangements of baffles on draft, as this will vary for

each stack. The location of the baffles will be limited to some extent by the fact that they can be put only in certain courses of tubes that are accessible. The kind and quality of coal used will affect the results obtained, and an arrangement of baffles which would be thoroughly satisfactory in the case of a coal high in fixed carbon and low in volatile might prove unsatisfactory in the case of a highly volatile coal. The grate area and depth, the height of the bridge wall, the size of the combustion chamber and other factors will enter into the matter of the thorough burning of the coal. Whatever influence these factors may have, the arrangement of the baffles will influence to a considerable degree the matter of fuel economy.

Conclusion

The high evaporation obtained when using coal averaging less than 14,000 B.t.u. per lb. indicates that the boiler practice as a whole was unusually good. In one instance an average efficiency for the test of 75.2 per cent was obtained.

While the efficiency obtained during these tests is unusually high as compared with what is considered good practice, it is to be noted that the tests recorded are merely one stage of a continuous test which has been made on these boilers for the past nine months and to which the best principles of boiler practice have been applied. The improvements made represent not only those gained by a study of the theory of boiler practice, but those gleaned from several years of continuous boiler testing under similar conditions.

The improvement over these nine months has been gradually noted after changing of grate area, height of bridge wall, method of firing and arrangement of baffles to suit the grade of coal used. The drums and tubes are kept thoroughly clean within and without, air leaks of all kinds are carefully avoided, the boilers are equipped with Dutch ovens and two of them are protected with asbestos covering. The firemen are thoroughly trained, work eight-hour periods, and, because of the similar load conditions for each shift, are kept constantly on that shift. The increased efficiency thus brought about is reflected not only in the evaporation per pound of coal, but is corroborated by a corresponding decrease in pounds of coal per kilowatt of output.

One of the primary reasons for the installation of a battery of three 500-hp. boilers rather than two of larger capacity was the advantage to be gained in the matter of efficiency when the boiler could be loaded for the full period to its rated capacity or better. A glance at the tabulation of boiler tests (see Table 1) will indicate that this was the case during these tests.

The conduct of such a test under commercial operating conditions brings into it certain factors beyond the control of the engineer. At first blush this appears to be a disadvantage, but when it is considered that the practical problems which the engineers must face are invariably influenced by unusual conditions and that one of the most important phases of engineering practice is the determination of these conditions and the explanation of their bearing upon the problem under consideration, it will be seen that such a test under operating conditions, in which there are many unforeseen influences, may be made of more value than a laboratory test, where such conditions would probably not be found. Another feature to be considered is that an expenditure of three or four thousand dollars for fuel and labor would hardly be made, even if justified by the results, except under operating conditions.

The conduct of such a series of tests, while a tedious undertaking, is one which would amply repay any operating engineer who is responsible for the burning of a large amount of fuel. There are few improvements in the boiler room that can be made at comparatively small expense which offer such encouraging possibilities along the line of the more economical evaporation of water as the arrangement of baffles in the boiler flues to meet best the definite conditions peculiar to any boiler room.

ADVANTAGES OF HIGH PRESSURE AND SUPERHEAT AS AFFECTING STEAM-PLANT EFFICIENCY

By ESKIL BERG,[1] SCHENECTADY, N. Y.

The advantages of the steam turbine as a prime mover are today too well known to need much discussion. It is, however, interesting to note that in the early stages of the development, when the thermodynamic efficiency was only about 50 or 60 per cent, it still had such great advantages over its competitor, the reciprocating engine, that it rapidly began to take its place. The chief reason for this is, of course, that outside of its mechanical advantages of simple rotation, it could advantageously use steam at the lower pressure ranges, and a vacuum of $28\frac{1}{2}$ in. or higher is now called for as standard by larger central stations.

The development of the steam turbine has advanced very rapidly, the designer has constantly had higher efficiency in view, and has in this respect succeeded so that today turbines are in operation that are giving a thermodynamic efficiency of almost 90 per cent. While in the future this already high efficiency may be improved by a small percentage, we will have to look to other features of the power plant for further gains in fuel economy. Such gains can be made by increasing the temperature range of the steam, but as the lower range is fixed by the temperature of the cooling water, the gain must be made by going to a higher temperature in the beginning of the cycle, which can be done either by the use of higher steam pressure or by the application of superheat. It will be shown later that a combination of both will give the best results.

Efficiency of a Turbine

The thermodynamic or Rankine-cycle efficiency of a turbine is the ratio of the mechanical energy taken out of the steam by the turbine to the total energy in the supplied steam when this steam is expanded adiabatically from the pressure at the throttle valve to the exhaust pressure in the turbine casing. (Adiabatic expansion takes place when the lowering of the temperature of the steam is done entirely by extraction of work from the steam.)

The steam consumption of a turbine when connected to an

[1] Engineer, General Electric Company.

Presented at a joint meeting of the Western Society of Engineers, the Chicago Section of the American Institute of Electrical Engineers, and the Chicago Section of The American Society of Mechanical Engineers, June 17, 1918.

electric generator is generally stated in pounds of steam per kilowatt-hour, and is the amount of steam required to deliver one kilowatt of electrical energy for one hour.

"Theoretical water rate" is a term generally used in all turbine investigations, and is the ratio of one kilowatt-hour expressed in foot-pounds (2,654,000) to the available energy in one pound of steam expressed in foot-pounds. The ratio, therefore, between the theoretical water rate and the actual measured water rate gives the efficiency. When the turbine is connected to an electric generator the combined efficiency of turbine and generator is generally given.

Formula for Calculation of Available Energy

The formula for calculating the available energy of steam expressed in foot-pounds, either dry or superheated, when expanding adiabatically to any back pressure, is seldom found in handbooks or textbooks, and when such formulæ are found they are rather complex and difficult to use. The formula can, however, be made very simple when expressed as the difference between the total heat input and the heat left in the liquid together with the latent heat in the mixture at the lower pressure. The formula then becomes:

Available energy in ft-lb. =

$$778\,[H_1 + C_p t_1 - (q_2 + x_2 r_2)]$$

where H_1 = total heat of saturated steam at initial pressure p_1
C_p = specific heat of superheated steam
t_1 = deg. fahr. superheat at pressure p_1
q_2 = heat of the liquid at lower pressure p_2
x_2 = quality of the steam at pressure p_2
r_2 = latent heat at pressure p_2.

All of these quantities are found in any steam table except x_2 (dryness factor), which is, however, easily calculated from the fact that the entropy is constant before and after the expansion.

Entropy of superheated steam is:

$$C_p \log_e \frac{T_1 + t_1}{T_1} + \frac{r_1}{T_1} + \phi_1$$

Entropy of moist steam is:

$$\frac{X_2 r_2}{T_2} + \phi_2$$

By making these equal and solving for x_2 there results:

$$x_2 = \frac{T_2}{r_2}\left(C_p \log_e \frac{T_1 + t_1}{T_1} + \frac{r_1}{T_1} + \phi_1 - \phi_2\right)$$

T_1 = absolute temperature at pressure p_1
T_2 = absolute temperature at pressure p_2
ϕ_1 = entropy of water at pressure p_1
ϕ_2 = entropy of water at pressure p_2

Example. Find the available energy of one pound of steam when expanding from 250 lb. gage pressure, with 250 deg. superheat, to 29 in. vacuum, (0.5 lb. abs.)

Available energy = $778\,[H_1 + C_p t_1 - (q_2 + x r_2)]$
$H_1 = 1202.3$
$C_p = 0.553$
$t_1 = 250$
$q_2 = 48$
$r_2 = 1046.7$

$$x_2 = \frac{T_2}{r_2}\left(C_p \log_e \frac{T_1 + t_1}{T_1} + \frac{r_1}{T_1} + \phi_1 - \phi_2\right)$$

$T_1 = 461 + 406.2 = 867.2$
$t_1 = 250$
$r_1 = 821.6$
$\phi = 0.5739$
$r_2 = 1046.7$
$T_2 = 461 + 80 = 541$
$\phi_2 = 0.0932$

$$x_2 = \frac{541}{1046.7}\left(0.553 \log_e \frac{1117.2}{867.2} + \frac{821.6}{867.2} + 0.5739 - 0.0932\right)$$
$$= \frac{541}{1046.7}\left(0.553 \times 0.2546 + 0.947 + 0.5739 - 0.0932\right)$$
$$= 0.5168 \times 1.5685 = 0.812$$

Dryness factor = 0.812

Available energy =
778 [1202.3 + 0.553 × 250 — (48 + 0.812 × 1046.7)] = 778 × 444.3 = 346,000 ft-lb.

[Theoretical water rate per kw-hr. = 2,654,000/346,000 = 7.67 lb.]

Gain by the Use of High Steam Pressure

It has long been recognized that a very large saving in fuel could be obtained by the use of high steam pressure. As early as 1897 DeLaval in Sweden supplied all the power for lighting the Exposition of Arts and Industries in Stockholm with his turbo-generating sets operated from boilers of his own design, using over 1500 lb. pressure. The units used were

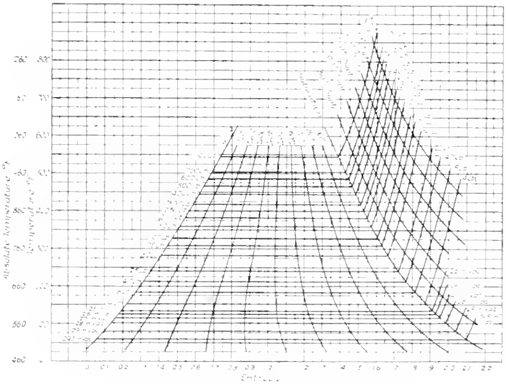

FIG. 1 ENTROPY-TEMPERATURE CURVES

naturally small, four of them having 100 hp. each and two of them 50 hp. each.

Boiler manufacturers in this country are today prepared to build boilers for 350 lb. pressure and see no difficulties in going to 500 lb. or even higher.

The theoretical gain due to the use of high steam pressure is plainly illustrated in Table 1, in which case 1 lb. of dry steam at 200 lb. pressure expanded to 28½ in. of vacuum is considered unity. It will be seen that by raising the boiler pressure to only 500 lb., there is a saving in fuel of 14.43 per cent. In money this saving would amount to about \$200,000 a year in a plant burning about 900 tons a day with coal costing \$5 a ton.

Theoretical Gain by Superheat

The theoretical gain by superheat is shown by Table 2, which is calculated on the basis of an initial pressure of 250 lb. gage expanded to a 29 in. vacuum. It will be seen that this gain is very small, being only 2.9 per cent when superheating up to 300 deg.

Practical Gain by Superheat

The practical gain by the use of superheat is often expressed by saying that the water rate is reduced 1 per cent for a certain number of degrees of superheat. The amount of this decrease varies with turbines of different design, but a figure

frequently used is 1 per cent gain in water rate for every 12.5 deg. of superheat. Column 5, Table 2, is based upon this assumption.

The actual net gain of fuel in per cent is therefore shown by column 8, which is the difference between column 7 and column 4. It will there be seen that the practical gain by superheat is about two and a half times as great as the theoretical. The reason for this large practical gain is that in a well-designed turbine of, say, the impulse type, the magnitude of the total losses is made up in about the following proportions when dry initial steam is used:

	Per Cent
Loss due to friction in nozzles and blades and windage loss of disks and blades	20
Leakage loss	3
Rejected energy (due to residual steam velocity)	3
Bearings, packings, etc.	1
Total losses	27
Efficiency of turbine	73

It will be seen that the first item is by far the most important one, and it is this item which is reduced by the use of superheat. The use of 200 deg. superheat will reduce the friction

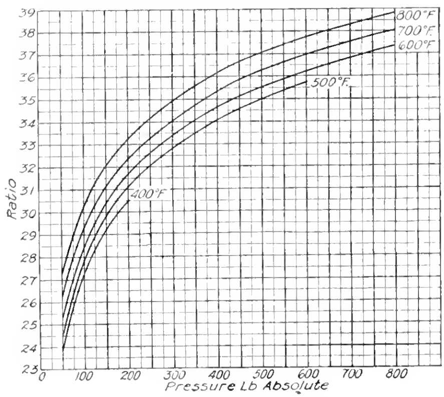

FIG. 2 CURVES SHOWING RATIO OF AVAILABLE B. T. U. IN STEAM TO TOTAL HEAT IN STEAM, FEEDWATER AT 90 DEG. FAHR.

and windage loss about one quarter or to 15 per cent, and the total loss would then be 22 per cent, making he turbine efficiency 78 per cent. This reduction is effected by the superheat reducing the moisture in all the stages. The reduction is best shown by the entropy-temperature diagram, Fig. 1. From this diagram it will be seen that starting with steam initially dry at 265 lb. absolute pressure and expanding it adiabatically to 29 in. vacuum through a turbine of 100 per cent efficiency, would result in steam of about 26.5 per cent moisture, whereas if the steam had been superheated to say 250 deg., this moisture would be reduced to about 19 per cent, a reduction of almost 30 per cent. In an actual turbine this percentage of moisture is of course a great deal lower, depending upon the efficiency.

Table 3 gives approximately the condition of the steam in all the stages of a ten-stage turbine, assuming the turbine has 80 per cent efficiency, is supplied with steam at 250 lb. gage pressure, 250 deg. superheat, and is exhausting into 29 in. vacuum. For comparison the last column of the table gives the steam condition in this turbine had the steam been initially dry.

EFFECT OF MOISTURE ON FRICTION

A great many formulæ and curves are given by various authors based upon experimental and theoretical data for calculating the friction losses, and they all have a constant which varies according to the conditions of the steam. Professor Moyer, for example, in his book on steam turbines gives a formula for rotation losses of buckets and wheel disks in which the constant C is as follows:

Superheat, deg			Per cent moisture		
100	50	0	5	10	20
$C = 0.875$	0.93	1.00	1.08	1.25	2.00

In other words, the friction loss is twice as great with 20 per cent moisture as it is with dry steam.

EFFECT OF THROTTLING

Throttling of dry steam always produces superheat; and it has often been said for this reason that there is practically no loss due to throttling, which is true as far as heat is concerned. There is, however, a considerable loss of available energy. The amount of superheat obtained by throttling is easily calculated because the total heat before and after throttling is the same. Assume that steam at 200 lb. absolute pressure is throttled down to 100 lb. absolute pressure:

TABLE 1 THEORETICAL GAIN DUE TO THE USE OF HIGH STEAM PRESSURE

Absolute pressure, lb.	Corresponding temperature, deg. fahr.	Total heat	Increase in total heat, per cent	Available energy in ft-lb. expanding to 28.5 in. vacuum	Increase of available energy, per cent	Net gain in fuel, per cent

200	606	336,000	1315 6	9.45	12.75	3.30	16	6.55
250	656	341,500	1340 5	11.50	14.60	3.10	20	8 50
300	706	347,000	1365.3	13.55	16.45	2.90	24	10.45

Total heat of dry steam at 200 lb. abs. = 1198.1

Total heat of dry steam at 100 lb. abs. = 1186.3

Assume that the specific heat of steam is 0.5:

$$1198.1 = 1186.3 + 0.5 \times t_1, \text{ or } t_1 = 23.6 \text{ deg.}$$

The available energy, however, assuming that the steam in both cases is expanded to 28.5 in. vacuum, is:

270,800 ft-lb. with 200 lb. pressure, dry steam

240,200 ft-lb. with 100 lb. pressure, 23.6 deg. superheat, or a loss in available energy of about 11 per cent.

Gain by the Combined Use of High Steam Pressure and Superheat

High steam pressure with no superheat has the disadvantage, as will be seen by the entropy diagram, of producing more moisture throughout the turbine, which means more friction. It is therefore advisable to combine high pressure with superheat so as to produce a more efficient turbine.

Fig. 2 shows the ratio of available British thermal units in steam to the total heat in the steam, with feedwater at a temperature of 90 deg.

The present practice in power plants in this country is to use, with turbine drive, a steam pressure of 200 lb. gage and about 150 deg. snperheat (temperature of 538 deg.), with a vacuum of 28.5 in. From Fig. 2 it will be seen that the ratio of maximum available heat for work to the total heat is only about 31.25 per cent.

TABLE 3 CONDITION OF STEAM IN THE VARIOUS STAGES OF A TEN-STAGE TURBINE

Assumptions: Steam pressure, 250 lb. gage; superheat, 250 deg.; vacuum at exhaust, 29 in.; turbine efficiency, 80 per cent.

Stages	Steam pressure, lb. per sq. in. abs.	Temperature of steam, deg. fahr.	Superheat, deg.	Per cent moisture	Per cent moisture assuming steam initially dry.

10	0.5	79		10.5	18.70

Steam temperatures as high as 700 deg. fahr. are now used in Europe, which with a steam pressure of 500 lb. would give 233 deg. superheat. The ratio of available heat for work would then be about 36.3 per cent, or a fuel saving over the above conditions of 16 per cent.

Turbine generator sets are now built having an overall efficiency of over 80 per cent inclnding generator losses, which with a boiler efficiency of 80 per cent would give an efficiency from fuel amounting to $36.3 \times 0.80 \times 0.80 = 23.25$ per cent. One kilowatt-honr = 3412 B.t.u., therefore the B.t.u. required to produce 1 kw-hr. at the switchboard=$3412/0.2325$=14,600.

On the other hand, had 800 lb. pressure and 800 deg. temperature been used, the efficiency would have been 38.75 per cent; and using a turbine efficiency of 85 per cent and a boiler efficiency of 88 per cent (which is obtainable with liquid fuel, forced draft, and preheated combustion air), a kilowatt-hour could be obtained by:

$$38.75 \times 0.88 \times 0.85 = 29 \text{ per cent, or}$$

$$\frac{3412}{0.29} = 11{,}750 \text{ B.t.u., or}$$

$$\frac{11{,}750}{19{,}000} \text{lb. of fuel oil} = 0.62 \text{ lb.}$$

Diesel-engine advocates now claim a consumption of about 0.55 lb. of fuel oil per kw-hr., but with a fuel about 50 per cent higher in price than the grade of fuel which can be satisfactorily burned under a boiler. It will thus be seen that when full advantage has been taken of the various processes that are used in transforming the energy of the fuel into mechanical energy through the medium of steam, the steam process compares quite favorably with results obtained at the present time with internal-combustion engines.

The conservation of our fuel resources is a subject which is being very carefully studied by all power-plant engineers at the present time, and improvements along the lines that have been discussed in this paper are now receiving serious consideration.

DISCUSSION

In the discussion following the presentation of the paper a number of questions were propounded which were taken up in order by the author as follows:

Dr. Thurston's remark to the effect that the most efficient all-round superheat would be that which would give dry steam in the exhaust, he said, was correct at the time when moderate steam pressure was used and the efficiency of the prime mover was around 50 per cent. Assuming however an efficiency in the prime mover of 80 per cent, 200 lb. steam pressure, and an exhaust pressure of $28\frac{1}{2}$ in. of vacuum, in order to obtain dry steam at the exhaust the superheat would be above 1000 deg. or in a territory that was practically unknown at the present time.

When the high-pressure boiler was developed, it would, in his opinion, be smaller, lighter, and cheaper per horsepower than the present boilers.

In regard to the question of moisture, for a given turbine efficiency the moisture was, of course, the same as the theoretical. If in practice the moisture was found to be excessive, it must be caused by the initial condition of the steam, either having less superheat than assumed, or it might be quite wet when entering the turbine.

In reply to the question whether the first 50 deg. of superheat was not more effective than the last 50 deg. of the 200, he would say that it was, because it reduced the moisture in the high-pressure end of the turbine where the friction loss is greatest. Turbine manufacturers recommended 50 deg. of superheat because it was easily obtained and it at least assured them of dry steam at the throttle. Very few boilers gave dry steam in practice.

In regard to high superheat showing a great saving in fuel with reciprocating engines, it was to be remarked that records of several European vessels operating with steam temperatures around 700 deg. showed that the saving in fuel was in some of them as high as 17 per cent and was sufficient to pay for the cost of installing the apparatus for producing superheat in a few trips across the ocean.

As to the inquiry made regarding the durability of packings, etc., at the higher pressures and temperatures, he would say that in all probability no packing would be used in the piping system and all joints would have to be welded. This, however, should not raise any difficulty. The paper had been primarily intended to point out the direction in which it was necessary for all to work in order to improve fuel economy, and to show that the advantages derived by the use of high steam pressure and superheat were infinitely greater than the disadvantages due to the few practical difficulties which had to be overcome.

A NEW SYSTEM OF REGENERATIVE EVAPORATION

By WM. L. DE BAUFRE, ANNAPOLIS, MD.

A NEW patented system of regenerative evaporation has been brought out recently in which the steam economy of multiple-effect operation is obtained with a single evaporator shell. This system has certain other unique advantages, and it may be applied to any make or type of evaporator. A brief description of the system will be given together with some of the test results obtained; but before doing so, the ordinary single- and multiple-effect systems will be described.

Single and Multiple-Effect Evaporators

The simplest method of evaporation is by the direct application of fire as diagrammatically illustrated in Fig. 1. The solution to be evaporated is contained in evaporator E, the vapor distilled off is condensed in condenser C, and the condensed vapor is collected in tank T. Evaporation takes place under atmospheric pressure and consequently at 212 deg. fahr. unless valve V be partly closed to throttle the flow of vapor to condenser C.

If evaporator E has not been designed with sufficient disengaging surface or ample vapor space, or if proper baffles are not provided, priming or the carrying over of particles of solution with the vapor will occur at atmospheric pressure. This priming may often be eliminated by operating at 5 lb. gage or higher for the reason that the volume of the vapor is thus considerably reduced. For example, the volume of 1 lb. of water vapor at 5 lb. gage is about 25 per cent less than at atmospheric pressure.

A considerable improvement in operation results by heating evaporator E with steam from a boiler B, see Fig. 2, thus providing a more readily controlled source of heat which is less liable to injure the evaporator E or its contents. The condensed steam is collected at S. Fig. 2 also shows the application of a pump P to produce a vacuum in evaporator E and thus carry on the evaporation at a temperature less than 212 deg. in cases where a better product is obtained thereby.

To maintain the evaporation in the single-effect plant shown in Fig. 2, somewhat more than one pound of steam must be supplied evaporator E for each pound of water vapor distilled off to condenser C. The ratio of steam to vapor varies but slightly with the steam and vapor pressures, but is greatly affected by the solution feed temperature. It is also affected by radiation from the evaporator and by loss of heat in the hot solution which must be discharged when the concentration within the evaporator reaches the limiting value. For sea-water evaporators, the loss due to radiation and blow-down is covered by assuming it equal to 5 per cent of the heat supplied in the steam.[2] Assuming an initial steam pressure of 125 lb. gage and atmospheric vapor pressure, it may readily be shown that the weight of steam supplied per pound of vapor produced is reduced from about 1.20 lb. with a feed temperature of 80 deg. fahr. to about 1.05 lb. with a feed temperature of 210 deg. Many methods of preheating the solution have been proposed and used, the most common probably being with exhaust steam from the evaporator feed pump.

Any further improvement in the steam economy of evaporators has been gotten in the past by resorting to the multiple-effect arrangement. Referring to Fig. 2, steam from boiler B is supplied to the steam jacket of the first effect E, but the vapor produced in E, instead of passing to condenser C, is condensed in the steam jacket of a second effect. Similarly, the vapor produced in the shell of the second effect is condensed in the steam jacket of a following effect, and so on until finally the vapor from the last effect is condensed in condenser C. On the assumption that 1.20 lb. of steam or vapor must be supplied each effect for the evaporation of 1 lb. of vapor therein, the relative steam economies in Table 1 are obtained for multiple-effect evaporators.

An inspection of Table 1 shows that very little additional saving in steam results by adding effects beyond the fourth:

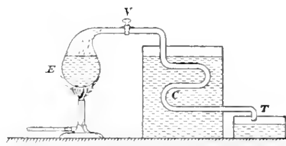

Fig. 1 Simple Method of Evaporation by Direct Application of Fire

in fact, most multiple-effect plants are limited to three or four effects with their complicated arrangements of piping, valves, traps, etc.

The New Regenerative Evaporative System

The essential feature of the new regenerative evaporative system which has been developed by the Regenerative Evaporator Company, of Baltimore, Md., is a highly efficient steam-

[1] Mechanical Engineer, U. S. Naval Engineering Experiment Station. Mem. Am. Soc. M.E.

[2] See Salt Water Evaporators, Calculation of Blow Down Loss, Heat Balance, Etc., by Wm. L. De Baufre, *Journal of the American Society of Naval Engineers*, November, 1915.

Abstract of a paper presented at a meeting of the Baltimore Section of The American Society of Mechanical Engineers, November 7, 1917.

jet compressor known as the "Jetflo" compressor and shown in Fig. 3. When applied to an evaporator in the manner represented in Fig. 4, the steam economy of a multiple-effect plant is attained with a simplicity of operation even greater than that of the ordinary single-effect plant.

Referring to Fig. 3, *S* is connected to the high pressure steam main, *V* to the vapor pipe from the evaporator shell and *E* to the steam jacket or more usually the steam coils within the evaporator shell, as represented in Fig. 4. With valve 3 closed and valve 2 open, the steam entering at *S* passes

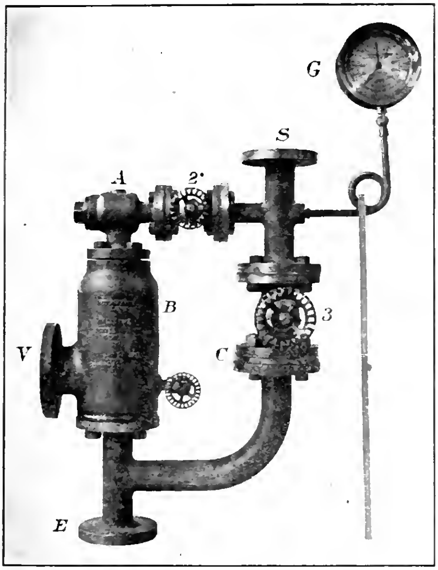

Fig. 3 The Jetflo Compressor

through a strainer in the head *A* and expands through nozzles in the compressor body *B*. At the outlet of the nozzles the steam by reason of its high velocity entrains a certain amount of vapor drawn from the evaporator through opening *V*. The commingled steam and vapor are compressed in a diffuser tube, also in the body *B* of the compressor, and are discharged through *E* into the steam coils of the evaporator with a pressure higher than the vapor pressure within the evaporator shell but lower than the initial steam pressure. Part of the vapor produced within the evaporator shell passes directly to the distiller condenser in the usual manner. The relative amounts of entrained and non-entrained vapor per pound of steam depend upon the design of the compressor and the temperature of the solution fed to the evaporator.

With valve 2 closed and valve 3 open, the steam bypasses the compressor and is supplied directly to the steam coils within the evaporator shell in the usual manner. An orifice in plate *C*, however, limits the flow of steam at the pressure available to that required for producing the maximum safe capacity of the evaporator.

The gage *G* not only indicates the pressure of the steam supplied but also the steam consumption of the evaporator with either the compressor or the bypass orifice in use. The inner scale is graduated to show the steam pressure in pounds per square inch gage. The outer scale is graduated to the capacity at which the evaporator is working, and when the reading is multiplied by a suitable constant, it gives the steam flow in pounds per hour.

The relation between the compressor and the evaporator is shown diagrammatically by Fig. 5 on which have been entered the data from a test run. The design of the compressor was such as to consume 147.8 lb. of steam per hour at 175 lb. gage pressure. The vapor pressure of 5 lb. gage within the evaporator shell was maintained by throttling the flow of non-entrained vapor to the distiller condenser. The efficiency of the compressor and the efficiency of the evaporator heating surface were then such as to set up a temperature difference between shell and coils of 16.8 deg. fahr. with 208.2 lb. of vapor entrained in the 147.8 lb. of steam, making 356 lb. of commingled steam and vapor to be condensed in the coils. There were produced in all 323.8 lb. of vapor, of which 115.6 lb. passed to the distiller condenser.

The data of Fig. 5 have been reduced to the basis of 1 lb. of vapor in Fig. 6, and the corresponding numbers of heat units have been entered thereon. From the standpoint of the evaporator alone, the performance is usual for a feed temperature of 200 deg. fahr., 1.10 lb. of commingled steam and vapor being required to produce 1 lb. of vapor. The function of the compressor was to make up 0.64 lb. of this mixture with entrained vapor, thus reducing the steam to 0.46 lb. The application of this compressor has thus saved 58 per cent of the steam that would have been required without it.

Test Results

The above data were obtained in a test made by Mr. M. C. Stuart at the U. S. Naval Engineering Experiment Station, Annapolis, Md., the results of which were summarized and

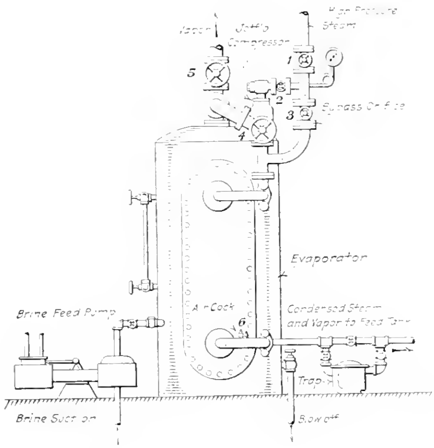

Fig. 4 Compressor of Fig. 3 Applied to an Evaporator

published in the *Journal of the American Society of Naval Engineers* for February 1918. [See abstract in The Journal, May 1918, pp. 245-247.—Editor.] While the compressor used was designed for 20 sq. ft. of heating surface in the evaporator and for an initial steam pressure of 175 lb. gage, the test covered the performance with 10 to 30 sq. ft. installed and with a range of initial steam pressure from 100 to 250 lb. gage.

The tabulated results of this test showed that the steam

economy was practically constant with a given evaporator over the wide range of steam pressures covered (averaging 0.017 lb. steam per lb. of total vapor with 20 sq. ft. of heating surface installed); and further, that the capacity produced was nearly proportional to the steam pressure (absolute). Hence the capacity of this regenerative system can be controlled without materially affecting its efficiency simply by throttling the steam supply.

One advantage of this regenerative system, however, is that the compressor can be designed for the desired capacity at the steam pressure available, thus eliminating the necessity of carefully regulating the steam supply. On naval vessels, the automatic pressure-reducing and regulating valve which it has been customary to install, may be eliminated when the compressor described is used.

Overload capacity at reduced efficiency is provided by the bypass, the orifice in which may be of such size as to pass at the available pressure the quantity of steam required to produce the maximum safe capacity of the evaporator. Since a careless attendant cannot operate the evaporator above its safe capacity, the purity of the fresh water obtained is assured. The operation of the evaporator is simplified by the application of such a compressor to the maintainance of the proper solution level within a single shell.

process must of course be continued until the desired concentration is attained. In the evaporation of sea water, however, the limiting concentration or salinity of the brine within the evaporator is determined by the danger of priming and the formation of scale and should not be permitted to exceed 3/32. A greater salinity is prevented either by a continuous or an intermittent blow-down. In the former case, the feed and blow-off valves are so regulated as to maintain a constant salinity of 3/32. In the latter case, the contents of the evaporator are completely discharged when the salinity reaches 3/32 and the shell refilled to the working level with sea water. The latter method is recommended for use with the compressors described by reason of the greater average efficiency of the heating surface and the cracking of the scale as explained below. Also, a schedule of blowing down can be worked out and followed without the necessity of taking salinometer readings.

As the evaporation of a solution proceeds, especially of sea water, the heating surfaces become coated with scale. Certain recent types of evaporators are so arranged that the scale may be cracked off the heating surface without opening the evaporator. This is accomplished by first turning off the steam supply, blowing out the evaporator contents, refilling to the operating level with cold brine, and finally suddenly admitting steam again. Difficulty with scale is reduced by operating with a low concentration, a low temperature and a small temperature difference.

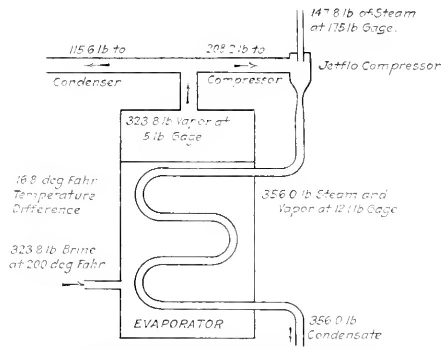

FIG. 5 DIAGRAMMATIC REPRESENTATION OF ACTION AND PERFORMANCE OF REGENERATIVE EVAPORATOR

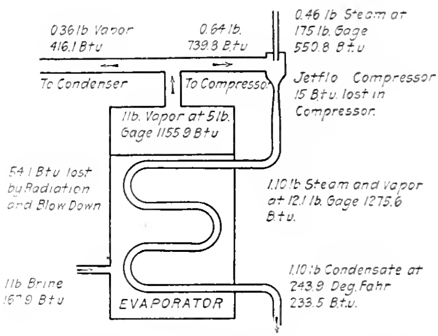

FIG. 6 HEAT BALANCE OF REGENERATIVE EVAPORATION SYSTEM

Operation of Evaporators

Several points in the operation of evaporators which must be observed are: freeing the steam coils of air; blowing down the concentrated solution; and scaling the coils.

In all apparatus heated by condensing steam, air and other non-condensable gases collect at the bottom of the steam space for the reason that air is about 50 per cent denser than dry saturated steam of the same pressure and temperature. Air cocks should therefore be provided on all evaporators near the point where the condensed steam leaves, as indicated at 6 in Fig. 4. This air cock should always be open to allow a perceptible escape of vapor during the operation of the evaporator; otherwise, the steam coils will become air bound and the capacity of the evaporator reduced.

As evaporation continues in an evaporator, the concentration of the solution increases with a consequent reduction in the efficiency of the heat-transferring surface. Where the object of evaporation is to secure a product of a given density, the

Evaporator Design

The steam economy of the ordinary single-effect or multiple-effect plant is practically independent of the design of the individual shells. The capacity, durability and ease of operation, however, are vitally affected by the design, so that different designs have been developed by experience for various classes of work. Some of the important points to be considered in design are: arrangement of steam space to produce a flow of steam across the heating surface and sweep away air and other non-condensable gases; arrangement of the solution space to produce if possible a circulation of the solution across the heating surface; sufficient volume of solution space to give a reasonable period between blow-downs; sufficient disengaging surface and vapor space to permit gravity separation of liquid from the vapor; placing of baffles so that the velocity of the vapor will be decreased rather than increased to aid the separation by inertia of the liquid from the vapor when the direction of flow is changed. With a Jetflo com-

pressor installed, the steam economy of the combination as well as the capacity is affected by the design of the evaporator.

Applications

The application of a steam-jet compressor of the type considered to the ordinary single-effect plant reduces the steam consumption by one-half and more, and the capacity obtainable depends upon the amount and efficiency of the heating surface installed in the evaporator. There is always obtainable, however, the original maximum capacity of the evaporator by means of the bypass. The compressor adds little weight and occupies practically no additional space. It is noiseless in operation, has no moving parts and retains its initial efficiency indefinitely. It makes for simplicity and safety in operation. The steam consumption of the evaporator and capacity at which it is working are indicated at all times.

In comparison with a multiple-effect plant, the same steam economy is obtained by applying a jet compressor to a single shell. This shell can be operated at atmospheric pressure; while, in a multiple-effect plant, the several shells must be of sufficient strength to withstand the high vapor pressures to which they are subjected. In the regenerative plant only one solution level need be attended to, unless it is considered desirable to divide the plant into two shells either of which may be operated at, say, quadruple-effect steam economy independently of the other shell.

On naval vessels, particularly destroyers, where two evaporators are installed for double-effect operation, the installation of these compressors enables either evaporator to be operated at triple-effect efficiency independently of the other evaporator. For a capacity of 7500 gal. per day this amounts to a saving on each destroyer of approximately 100 gal. of fuel oil per day in comparison with double-effect operation, and 400 gal. in comparison with single-effect operation. On many of the present naval vessels, the full rated capacity of the evaporators can be obtained with such compressors operating at triple-effect efficiency.

On merchant-marine vessels it is usual to install one evaporator only for make-up feed. The installation of a Jetflo compressor reduces the amount of coal burned for this purpose by 50 per cent and more. On some vessels it has been customary to carry 100 to 200 tons of fresh water for make-up feed and not to use the evaporator. To produce 100 tons of fresh water with an evaporator equipped with the compressor described would require approximately 7 tons of coal. It is questioned whether more than 7 tons of coal are not burned to carry 100 tons of make-up feed 3000 miles across the Atlantic. With weighty material such as coal and metals, the total cargo is limited by weight and not by the volume of the cargo space; hence the absence of 100 tons of make-up feedwater would enable the carrying of just that additional amount of cargo.

In many steam-generating plants the question of securing pure make-up feedwater is an acute one, particularly where superheaters are used. The least amount of sediment carried over by the moisture in the steam is deposited on the superheater surfaces. The use of evaporators equipped with Jetflo compressors insures the purest obtainable make-up feedwater with minimum expenditure of fuel to obtain it.

For the evaporation of milk and similar materials requiring narrow ranges of temperature operation and consequently low temperature differences, these compressors are peculiarly adapted. The evaporation can be carried out at any desired temperature above or below that corresponding to atmospheric pressure, and with high steam economy and great simplicity in operation. They can be readily applied to evaporators now in operation with but slight changes in the piping only. They are also suitable for operation with any make or type of chemical evaporator in which the object of the evaporation is the concentration of the product.

THE PUBLIC INTEREST AS THE BEDROCK OF PROFESSIONAL PRACTICE

Enlivening Discussion of Mr. Cooke's Paper at the Spring Meeting on the Responsibilities and Obligations of Engineers and Their Organizations, with a Summary of the Objects of Various Professional Societies

A discussion at the Spring Meeting which evoked a great deal of interest was that upon the paper by Morris L. Cooke on The Public Interest as the Bedrock of Professional Practice.[1] *This paper consists mainly of a review of the statements of purposes of various engineering and other professional organizations, as embodied in their constitutions or codes of ethics. The specific purpose of the author was to determine what has been, and is now, the attitude of engineering organizations toward the public interest. By this means he sought to develop the engineer's concept of his public relationships and responsibilities as contrasted with such relatively minor obligations as those to the profession of engineering, to a client, to fellow-engineers, and to himself.*

The Author,[2] in presenting his paper at the meeting, referred to features typical of the codes of the various engineering societies. These usually include references to an engineer's relations to his firm and his clients; his relationship to his fellow engineers; the maintenance of the standards of the profession; and some other requirements, as, for example, a deprecation of advertising.

In our own code we have introduced a section relative to the engineer's relations to the public which slightly, though not materially, modifies and enlarges the scope of the codes as usually drafted. The significant statement in the A.S.M.E. code, however, is that the engineer should consider the protection of clients' or employers' interests his first obligation and, therefore, avoid every act that could be considered as in any way contrary to his duty.

In contrast are the principles of professional practice of our professional brothers, the architects, which decree that the architect should not engage in, nor encourage, any practice contrary to law or hostile to the public interests, even under his client's instructions; for, as he is not obliged to accept a given piece of work, he cannot, by pleading that he has but followed his client's instructions, escape the condemnation attaching to his unethical or unlawful acts.

[2] Washington Representative, U. S. Shipping Board, Emergency Fleet Corporation, Washington, D. C. Mem.Am.Soc.M.E.

The medical profession has for its prime object the service it can render to humanity. Reward or financial gain should be a subordinate consideration. In choosing this profession, an individual assumes an obligation to conduct himself in accord with its ideals. The following is from the code of the medical profession:

"Physicians should warn the public against the devices practiced and the false pretenses made by the charlatans, which may cause injury to health and loss of life"—a very emphatic statement. We find the same idea in the lawyers' code, which ends as follows: "Above all, a lawyer will find his highest honor in a deserved reputation for fidelity to private trust and to public duty as an honest man and as a patriotic and loyal citizen."

"Unfortunately," the author said, "my experience as an engineer and as a public official has given me the best of reasons for believing that this spirit is not representative of the engineering ethics of today."

High National Standards Depend on High Individual Standards

Bringing the matter onto a national basis, he said that recently in reading the life of John Fiske[1] he had found the following significant quotation relative to the moral principles of the Civil War:

> President Lincoln, by the summer of 1862, had come to see that the war as it had been conducted by the Administration had no clearly defined moral issue back of it, and that he could no longer find justification in continuing such a terrible conflict as he was waging against the people of the Southern States on the sole issue of an interpretation of the Constitution. He saw the necessity, for the salvation of the Nation, of getting the issue squarely on its merits as a moral issue—a conflict between the idea of freedom and the idea of slavery, and then uniting the moral and political forces of the North in support of this policy.
>
> To this end he moved on his own initiative; and one of the finest chapters in all statesmanship is the history of his skill, his patience, his wisdom, his faith in rousing the dominant moral feeling of the North and focussing it in support of his Proclamation of Emancipation.

Similarly, the speaker believed that the successful prosecution of the present war would be largely a question of our ability to keep it where President Wilson had placed it, namely, on high moral ground. This is not the work of one man, but of all the people. It is our work in all our relationships, whether they be those of town life, church life, or professional life. In this hour of real national peril, can we do less than write into our code that from this day forth it is unprofessional for an engineer to safeguard any private or special interest at the sacrifice of public welfare? Do we seek power, influence, prestige, opportunities? These and more will come when we provide for our profession this moral leadership.

Now is the Time for Code Revision

Fred J. Miller[2] (written). I think the actual attitude and practice of our members with regard to public service are far in advance of our code.

If American citizenship means anything, it means that no citizen can honorably take part in work that he knows to be against the public interest, and that principle applies to engineers, as well as to doctors, lawyers and architects.

[1] John Fiske, Life and Letters, by John Spencer Clark, vol. 1, p. 189.

[2] Major, Ordnance Reserve Corps, Ordnance Department, Rock Island Arsenal, Rock Island, Ill. Mem.Am.Soc.M.E.

Now, when so many are making sacrifices for the general good, not only of our own country but of the whole world, would seem to be the proper time to rewrite our code in the spirit of the times.

Richard A. Feiss[1] (written). Today every calling involves special knowledge and special training and the men pursuing these callings in the field or in the workshop must view their work as professional work; for each calling is today a profession. The majority, moreover, of these new professions are to be classified under the head of "engineering." The men pursuing them are by every right eligible to membership in the engineering societies. The vast majority of all these "engineering professions" are dealing more and more concretely and specifically with the handling of organized human effort. This involves social and other problems inherently of public interest.

We have all learned during the years of the war at least one thing—that no man or group of men are a law unto themselves. A man's rank or the rank of any association or group of men is no longer to be judged by the amount of worldly goods he may possess, or the amount of knowledge, or the accident of birth, but solely by the quantity and quality of service to the common good. It is therefore necessary that a society of professional men such as this take the leadership in making its prime object the setting up of standards for the profession and the development of a membership whose object is first of all the best service in both quality and quantity to the public interest.

H. J. Macintire[2] (written). We are living in an era of change. Ante-bellum conditions both in the material and spiritual world are probably gone forever and when the war ends we must face a period of reconstruction. In this new time about to dawn the heavy national debts will have to be assumed by the rich whose wealth will thus be depleted, while the increased wage of labor is automatically raising the material level of the mass of labor.

Standing between these two classes, materially speaking, is the professional man, who will have a chance such as he has never had before. Having maintained a position at neither of the extremes of society, he will be in a position for calmer judgments, for firmer progress. He will be called upon for leadership, but he can make his position enviable and assume this leadership deservedly only by such conduct as will command the esteem and confidence of the public and the respect of his fellow-engineers.

The engineer, in common with every person of education and sensibility, should be guided by the spirit of the law instead of by a slavish adherence to the letter. And surely it is not too much to ask that The American Society of Mechanical Engineers take the lead in demanding this broader ideal by so framing its code that every member of the society will be under pressure as a member (as well as an individual) to consider the interest of the community to be his greatest responsibility.

Suggestions for Code Revision

John B. Mayo[3] (written). I have read Mr. Cooke's paper and greatly admire its spirit. I find nothing to criticise and

[1] Gen. Mgr., The Joseph & Feiss Co., Cleveland, Ohio. Assoc. Am. Soc. M. E.

[2] Assistant Professor of Mechanical Engineering, University of Washington, Seattle, Wash.

[3] In Drafting Department, Electric Boat Company, Groton, Conn. Mem.Am.Soc.M.E.

cannot add to it except to remark that it has always seemed to me that the public interest might well be led up to by a reference to the description on the certificate which is framed and hangs in my hall and is signed by Eckley B. Coxe and reads thus:

"An organization for promoting acquisition of that knowledge which is necessary to the mechanical engineer to enable him most effectively to adapt the achievements of science and art to the use of mankind."

Robert J. Hearne[1] (written). That the code of ethics of The American Society of Mechanical Engineers may need rewriting, is natural; but there is nothing in the code which is directly antagonistic to the consideration of the public welfare by an engineer. The code must be read as a whole.

Although one section states that "the engineer should consider the protection of a client's or employer's interest his first obligation," yet the preceding section says he must "be governed by principles of honor and honesty and should satisfy himself . . . that the enterprise . . . is of legitimate character, and if it is of questionable character he should sever his connection with it as soon as practicable, *avoiding in so doing reflections on his previous associates*." (The italics are mine in this case, and are used to emphasize the last paragraph, which I think were better omitted.)

There are times for keeping silent, and there are times when one should speak out, and if a man is satisfied that his former associates are connected with a disreputable enterprise he should not keep silent, even if it hurts him to speak. It surely is unethical to keep silent when one knows of wrongdoing or incompetence.

It would be well, I think, to amend the section first referred to as follows:

> "The engineer should consider the protection of a client's or employer's interests his first obligation, and, therefore, should avoid every act contrary to his duty, *provided, however, that his client's or employer's interest does not infringe the rights of the public or any individual.*"

Charles M. Horton[2] contributed an interesting discussion of the ethics of daily life, the distinction between right and wrong, and the influence of environment, training and the conditions of existence. The discussion does not bear abstracting and space, unfortunately, does not permit its use here in its entirety. Mr. Horton's conclusion, however is here quoted:

"So let us write our code. And let it begin with a phrase having to do with a broad, spiritual outlook upon life, with reference to our profession, and let it end with a kindred generous phrase. Let us not talk of things having to do with the 'unprofessional' and 'inconsistent' and 'undignified.' Let us forget that kind of admonition. We do not need it. What we do need, though, and which should be embodied in the code, is forceful language having to do with the spirit embodied in the phrase of 'live and let live'—the things which, after all, are necessary if life shall be worth the living, not physically but spiritually, and a living to all, for all. Let us not be negative. Let it be written what we shall do, not what we shall not do; the negative, through inference, will take care of itself—and woe unto him who disobeys and is found guilty. Such a code would be eminently practicable. Such a code we should write. We cannot do more; we certainly should not do less. Let us go big in this thing, and let the Society stand behind it to a man."

[1] Secy-Treas., Durbrow & Hearne Mfg. Co., New York, N. Y. Mem. Am.Soc.M.E.

Unfair Dealings with the Government Deprecated

C. Wellington Koiner[1] (written). In times of peace the best interests of the Government are not considered very seriously. The principle of "every fellow for himself and the devil take the hindmost," is usually carried out to the letter. Special privilege is sought and obtained regardless of the effect on public interest; as an illustration, too many people take the stand that the Government must not be permitted to do anything aside from certain negative functions, as it were, especially if somebody is making money out of the things that the Government should do. The scandalous claims and setups for intangible values that have been made recently before the railroad commissions and other regulating bodies is another illustration of how far some lawyers and some engineers will go in opposition to the public interest and in violation of their code of ethics.

"All for the state and the state for all" means that her interest is to be considered first and at all times conserved, in order that we, as individuals, may, at all times, receive the maximum benefits from her protection.

I heartily subscribe to Mr. Cooke's sentiment that "every code now in use by engineers in this country and abroad should be entirely rewritten on much broader lines and in a more inspiring key."

Thomas M. Roberts[2] (written). Business methods of long usage are in practice among engineers and contractors, and the custom of driving a sharp bargain is too often passed as legitimate. Such methods may be expected between man and man as long as ethical standards are held cheaply or of little value. But we may well consider their effect on our country and its Government during war, as well as the reflex action on the influence of engineers in public life.

It seems unfortunate that the Government in assembling war materials is repeatedly handicapped by the covert efforts of some engineer-contractors to insert in their specifications misleading phrases which to the Government officials seem correct, yet later result in considerable trouble and loss to the project in development. These men and their specified bids for public service cover the letter of the law, but they violate the ethical features of honest professional practice.

Mr. Roberts then cited specific instances of questionable practices in dealing with the Government in which the contractor inserted in his bid certain modifications of the original specifications which the Government was prevailed upon to accept and which became legal as soon as the bids were signed. Later, when the apparatus agreed upon was found inadequate, the Government was obliged to revert to the requirements of the specifications in order to secure satisfactory results, and had to pay the difference in cost between the device originally called for and the device offered in the bid.

"These examples," he wrote, "may not strictly be classed as acts of 'Aiding the Enemy,' but they represent a species of unethical dealings which no society of engineers or engineer-contractors should countenance.

"Let us emphasize this fundamental feature of our republic

[1] Gen. Mgr. and Engineer, Pasadena (Cal.) Municipal Light & Power Co. Mem.Am.Soc.M.E.

[2] Bureau of Yards and Docks, Navy Department, Washington, D. C. Mem.Am.Soc.M.E.

that a public interest is inseparably bound to the common welfare, and therefore every engineer and engineer-contractor in dealing with a public interest is bound by an ethical tie, which is paramount to the written law, and he should have a keen sense of justice toward the public commonweal."

Conditions Not as Bad as They Seem

Thornton Lewis[1] (written). While it is true that the codes of ethics of the various organized engineering societies are sadly lacking in definite expression upon the obligation of engineers to the public interest, nevertheless my observation leads me to believe that engineers as a class fulfill their duty to the public just as faithfully as the men of the other professions such as doctors, lawyers, etc.

This is no reason, however, why our codes should not express the fact that public interest is the first duty. In fact, there are many positive reasons why they should do this. Among them may be mentioned the inspiration and stimulation to unselfish action which the younger men of our profession would and should receive from our codes. The very nature of our profession carries many of our members to wild or remote places where they necessarily are out of touch with any large body of engineers, and so have no opportunity for consultation as to the relation of engineers to the public. Definite standards of conduct and expressed ideals in our codes would be of inestimable value to them in their endeavors to hold true to the best that is in them and their profession.

Since engineers more and more are becoming dominating factors in public-service corporations and the manufacturing industries, can we not in reality bring around a better condition of society in general by helping them to see more clearly the path of duty to the public, which, in the long run, will be to the best interests of their corporations and to their best selves?

Our new codes of ethics must embody the thought that he who serves humanity most serves himself best.

A. F. Nagle[2] (written). I regret to differ with the author, whom I believe to be actuated by sincere motives; nevertheless, I believe his paper is uncalled for.

That the founders of the Society were not indifferent to the ethical, or moral, character of its membership, is evidenced by the fact that they required a rigid search to be made by the Council into an applicant's experience and character, and if favorably acted upon, his name was to be submitted to a voting membership, consisting, at present, of over 8000, where but *two* negative votes would exclude him (see C 17). What an ordeal to go through! It is a wonder that any of us could pass through it. If, perchance, a bad man should slip in, he can at any time be expelled by a two-thirds vote of the Council (see C 25), hence one has to be not only a good man to get in but he has to remain good to stay in.

Mr. Cooke's plea that the public interest, be it city, state, nation, or humanity at large, should have paramount service from us, prompts me to ask what is implied. If our engineer be the sort of man we rightly assume him to be, he will deal faithfully with all his clients. What more can he do? I have been in the employ of cities, state and nation nearly one-half of my business life, and I can unhesitatingly say that the personnel of the engineers I have met in the public service have compared very favorably with those outside.

[1] Lewis, Robinson & Grant, Philadelphia, Pa.

[2] Elmira, N. Y. Mem.Am.Soc.M.E.

Engineers as Legislators

Oberlin Smith[1] said that while it is undoubtedly true that the engineering profession owes much to the public which has fostered and used its work, the statement regarding the duty of engineers to the public suggests, per contra, what duties the public owes to engineers. In this progressive age, with its enormous increase in efficiency due almost altogether to engineering inventions, why do we see our halls of Congress peopled with lawyers, merchants and farmers, not to say professional politicians, with scarcely an engineer in the whole conclave? The engineers, with their brethren, the architects and physicians, have not only collaborated in the building up of science and art, but of the good morals and the health and wealth of their communities. They certainly have a large share in the making of laws which tend to greater production, with greater efficiency, of the tools with which our civilization is builded.

As most of us do not have time to become practical politicians, we must depend upon our non-engineering friends to work gradually toward such a reform. This can only be done by the promotion of a proper enlightened sentiment among the mass of the people.

Correct Ethics Should Be Taught the Student

Constructor James Reed, Jr., U. S. N.[2] (written). The paper starts with the statement that "the members of our Society *individually* are doing everything in their power to help win the war" (italics are mine). We of the Government's permanent staff of engineers are tempted to elide that word "individually," or else add to it the words "and *collectively*," so magnificent has been the patriotic response to the Government's need on the part of the engineering societies and their members. Even in peace times we have believed we were a patriotic nation, but our patriotic duties did not embrace the broader view of what comprises real patriotism, namely, a consideration of the public interest always.

Judging from my own educational experiences at technical schools, there is at such schools an almost complete lack of emphasis placed on the importance of realization by engineers of the public interest.

I firmly believe here is the remedy: a thorough and constant teaching at our engineering schools of the higher ethics of the profession, the citizenship duty of the engineer, just as at our West Point and Annapolis the highest ideals of patriotism and loyalty are unceasingly held before the students.

I have never forgotten marching into section room one morning for recitation when a month-old "plebe" at Annapolis, and hearing the lieutenant instructor, standing erect before the class, say impressively, "Gentlemen—before you take your seats—you have read in the morning papers of the death of Lieutenant Philip Lansdale, U. S. N., killed in action in Samoa, and of Ensign Monahan, who refused to leave his wounded superior and fell while trying to clear a jammed Colt automatic to hold off the enemy. Always remember this act: in it are embodied all of the best traditions of our service!" I therefore offer the suggestion that a constant effort be made to hold before the student the importance of this realization in the practice of his profession, that the public interest is not to be forgotten or put aside for the benefit of the corporate interest.

[2] Mare Island Navy Yard, Vallejo, Cal. Mem.Am.Soc.M.E.

Resolution on Modification of Aims of the Society

L. P. Alford.[1] The discussion clearly calls for us to reframe our code of ethics. We ought to associate with that reframing the restatement of another provision of the Society, namely, the statement of the aims and objects expressed in our Constitution. They are quite narrow and technical, yet the tendency for the last few years has been to make the Society industrial rather than purely a society of mechanical engineering. We have broadened the activities of the Society beyond its statement of aims. The restatement of the code of ethics is to reframe for us the ideal of the duties of the engineer. When the revised draft of the code of ethics is presented there should also be presented a consistent revised draft of the objects and aims of the Society.

The following resolution was then introduced by Mr. Alford, and was carried by vote of the meeting:

> Because of the interest aroused by the paper presented by Mr. Morris L. Cooke at the Worcester meeting, and because of the frequently expressed belief that the work and activities of The American Society of Mechanical Engineers have outgrown its statement of aims and objects, it is respectfully suggested to the Council of the Society that steps be taken to reformulate the objects and aims of the Society as presented in the Constitution, and to recast the Code of Ethics of The Society to bring these in keeping with the interests and activities of the Society as a whole.

Professional Ideals

Calvin W. Rice. I have been making the spirit of this paper a religion in my administration of the office of Secretary of the Society and welcome this opportunity to express my faith in the ideals of the engineering profession.

Mr. Cooke referred to the way in which President Lincoln aroused the dormant moral feeling of the North in the support of his proclamation of emancipation, and I want to point out that from the very fact that this feeling *was* dormant, it already existed in the minds and hearts of the people and needed merely to be aroused.

Mr. Cooke has also told how President Wilson, with great ability, sensed the ideals of the Nation in this time of the world war. In the same way as before, these ideals were already existent and needed only to be phrased; and I claim for the engineers of the country, as individuals and idealists in an ideal profession, that they have contributed their share to the state of opinion and to the ideals of the nation in this present war, such as the President has expressed.

As a concrete example of the point I am making, I have just returned from a trip to the Sections of the Society and stopped at Dayton, Ohio. There I found the magnificent new clubhouse of the Dayton Engineers' Club, donated to the engineers of that city by two members of our Society. It is of chaste architecture and is located on a beautiful site overlooking the river. What is more important than this, however, is the fact that the club, as stated in the literature which it issues, is dedicated to *the dissemination of truth* and to *the creation of civic righteousness.*

This is a cheering example of the new spirit of the Nation, which shows that in this case at least the engineering profession is alive to the spirit of the times.

I have made a study (see Appendix) of the stated objects of the scientific societies of the world: of the English societies, the Royal Society, the Institution of Civil Engineers, which is the oldest engineering society—it celebrated its one hundredth anniversary just a few months ago; the societies in France, the Academy as well as La Société, corresponding to our engineering society; the Italian societies; and the societies of America, including the National Academy of Sciences. It is no reflection upon our Society that it does not stand out preëminent above all the others in its stated objects, or that it falls behind our new national ideals. There is only one society and, strange to say, it is in Germany, that in its constitution approaches what we here aim to do. As nearly as I can remember the objects of the Verein Deutscher Ingenieure are twofold: devotion to the engineering profession, and to the development of engineering *for the benefit of the Fatherland.* Here, however, the one thing is lacking that we find lacking in the whole of Germany. There is no expression of the spirit—it is all for the state.

It is not sufficient that we have the objects of this Society and of our profession for the benefit alone of the United States of America. That would be far short of the goal. We must, as Dr. Hollis has exhorted us, reconsecrate ourselves to our new ideals, as displayed in the dedication of the Dayton Engineers' Club.

Mr. Rice then stated that he had noted in the public press that Mr. Isham Randolph, a former director of the American Society of Civil Engineers, had been extended an invitation, either through Mr. Cooke or through some appropriate convention, to prepare a new code of ethics for our profession. He recommended that the Society should get in touch with Mr. Randolph so that he might include a statement applicable to mechanical engineers.

Later a motion was made and carried by the meeting requesting the Secretary to communicate with Mr. Randolph.

R. Sanford Riley,[1] speaking as the President of the Worcester Chamber of Commerce, as well as one of the older members of the Society, referred to the broadening conception of the engineering profession, and said that when he entered the profession he had not realized that engineers were as well qualified as others for service to their country. It is easy to criticise engineers because of the fact that Congress is filled with lawyers and others in lines of business different from our own; but it is largely our own fault. We are growing in numbers, and growing in importance. To grow proportionately in power we must be interested in larger affairs than our own. Worcester is important as a city largely because it is a city of engineers. They continue so large a proportion of the community that from necessity they have formed the habit of doing things in a public way—and the city has not lost anything in consequence.

The Author, in closing, called attention to a remarkable document, A Study in Hospital Efficiency, comprising a case report of the first five years of a private hospital, by E. A. Codman, M.D., 15 Pinckney St., Boston. The price of the report is $1. This report is remarkable because it analyzes with freedom and truthfulness every case treated and shows whether there were errors on the part of the surgeon through poor diagnosis or lack of technique; faults in nursing; faults on the part of the patient, etc. This was instanced by the author as an advanced step in professional ideals. The report also constitutes a strong condemnation of fee splitting, which so often leads to unnecessary surgery. The application to other professions is obvious.

APPENDIX [1]

OBJECTS OF PROFESSIONAL SOCIETIES CLASSIFIED

In examining the objects of some ninety of the largest and better-known professional societies, including professions other than engineering, both of the United States and abroad, the resemblances are found to be many. In the great majority of the societies the objects incline toward the advancement of their respective professions, the improvement of the professional standing of their members and the fostering of the social spirit within the various groups. Practically all agree as to the methods to be employed in attaining these objects—the establishment of society rooms, the holding of frequent meetings, both social and professional, the presentation of papers and the soliciting of discussion, with their publication and distribution to the membership through the medium of monthly journals or bulletins or yearly transactions.

A limited classification has been made to show in a very general way how the societies are grouped under certain headings. In most cases, of course, a society is mentioned in connection with two or three different objects, all of which it may desire to attain.

Perhaps the aim most frequently stated is the advancement of a particular science (usually incorporated in the name of the society) or in some cases of two or three of the allied sciences. Below is given in tabulated form the list of such societies with the wording used by them in this connection:

American Bar Association—to advance the science of jurisprudence
American Chemical Society—advancement of chemistry
American Electrochemical Society—advancement of the theory and practice of electrochemistry
American Institute of Accountants—to advance the science of accountancy
American Mathematical Society—to encourage and maintain an active interest in mathematical science
American Physical Society—advancement and diffusion of the knowledge of physics
American Political Science Association—encouragement of the scientific study of politics, public law, administration and diplomacy
American Water Works Association—the advance of knowledge of the design, construction, operation and management of water works
California Academy of Sciences—the promotion of science
Cleveland Engineering Society—the advancement of engineering, architecture and applied science
Chemists' Club of New York—the advancement of the science and application of chemistry
Clinical Society of London—cultivation and promotion of the study of practical medium and surgery
Franklin Institute of the State of Pennsylvania—the promotion and encouragement of manufactures and the mechanical and useful arts
Institution of Civil Engineers—promoting the acquisition of that species of knowledge which constitutes the profession of a civil engineer.
Institution of Mechanical Engineers—to promote the science and practice of mechanical construction
International Association of Municipal Electricians—the acquisition of knowledge relating to fire, telegraph, heat, light and power systems
Mineralogical Society—to advance the study of mineralogy, crystallography and petrology
National Fire Protection Association—to promote the science and improve the methods of fire protection and prevention
New York Academy of Medicine—investigation and promotion of the science and art of medicine
New England Water Works Association—advancement of knowledge relating to water works and water supply
North East Coast Institution of Engineers and Shipbuilders—the advancement of the sciences of engineering and shipbuilding
New York Electrical Society—dissemination of the knowledge of theoretical and applied electricity.
Oregon Society of Engineers—to advance the science of engineering and architecture
Philosophical Society of England—the furtherance of philosophy as a separate science
Surveyors' Institution—the acquisition of that knowledge which constitutes the profession of a surveyor
Western Association of Technical Chemists and Metallurgists—the general advancement of technical chemistry
Society of Mineral Industry—the progress of the mining and metallurgical arts
French Physical Society—the advance of physical science
International Society of Electricians—to promote the popularization and development of electricity
Swiss Society of Engineers and Architects—to encourage progress in architecture and mechanics

The promotion of the arts and sciences in connection with their respective lines of endeavor is another important end to be attained and the following societies have so worded this clause:

Aeronautical Society of America—the advancement of the theory and practice of aeronautics and of the allied arts and sciences
American Institute of Electrical Engineers—the advancement of the theory and practice of electrical engineering and of the allied arts and sciences
American Institute of Mining Engineers—to promote the arts and sciences in connection with the economic production of the useful minerals and metals
The American Society of Mechanical Engineers—to promote the arts and sciences in connection with engineering and mechanical construction
American Society of Refrigerating Engineers—to promote the arts and sciences connected with refrigerating engineering
Institute of Radio Engineers—the advancement of the theory and practice of radio engineering and of the allied arts and sciences
National Electric Light Association—activities shall be for the fullest development of the electrical engineering arts and sciences in all their branches
Society of Automotive Engineers—to promote the arts and sciences connected with the design and construction of automobiles, self-propelled or mechanically propelled mediums for the transportation of passengers or freight, and internal-combustion prime movers
United Engineering Society—to advance the engineering arts and sciences in all their branches
Institutio Polytechnico Brazileiro Escola Polytechnica—the study and diffusion of theoretical and practical knowledge of different branches of engineering and of the auxiliary sciences and arts

The advancement of engineering knowledge and practice is the statement in a general way of the aims of the following societies:

American Society of Civil Engineers—the advancement of engineering knowledge and practice
Engineers' Society of Northeastern Pennsylvania—the advancement of engineering knowledge and practice
Engineers' Society of Pennsylvania—the advancement of engineering in its several branches
Engineers' Society of Western Pennsylvania—the advancement of engineering in its several branches
Oregon Society of Engineers—to advance the science and practice of engineering
Society of Engineers of Eastern New York—the advancement of engineering in its several branches
Washington Society of Engineers—the advancement of engineering knowledge and practice
Western Australian Institution of Engineers—the advancement of engineering knowledge and practice
Western Society of Engineers—the advancement of the science of engineering

Another and very important purpose of a professional society is the maintenance of high professional standards. The methods of expressing this purpose are so nearly alike

[1] To accompany remarks of the Secretary.

that merely the names of those societies avowing it are given:

American Association of Engineers
American Bar Association
American Institute of Accountants
American Institute of Electrical Engineers
American Society of Civil Engineers
American Society of Engineering Contractors
American Society of Heating and Ventilating Engineers
Engineers' Society of Northeastern Pennsylvania
Engineers' Society of Pennsylvania
Engineers' Society of Western Pennsylvania
Florida Engineering Society
Institute of Radio Engineers
Mining and Metallurgical Society of America
Municipal Engineers of the City of New York
Oregon Society of Engineers
Society of Engineers of Eastern New York
Society of Municipal Engineers of the City of Philadelphia
Washington Society of Engineers
Western Australian Institution of Engineers
Swiss Society of Engineers and Architects

Either for social or professional reasons, and often for both, all societies desire to further intercourse among their members and they employ the same methods of meetings, publications and correspondence.

Research plays a large part in the aims of many, as the following enumeration shows:

American Association for the Advancement of Science—to give a stronger and more generous impulse and a more systematic direction to scientific inquiry
British Association for the Advancement of Science—to give a stronger impulse and a more systematic direction to scientific inquiry
Canadian Society of Civil Engineers—to encourage original investigation
Colorado Scientific Society—the promotion of scientific observation
Michigan Academy of Science—encouragement of research
National Academy of Sciences—to investigate, examine, experiment and report on any subject of science
New York Academy of Medicine—the investigation of the science and art of medicine
Rensselaer Society of Engineers—the encouragement of original scientific research
Royal Society of Canada—to aid researches
Belgian Royal Academy of Sciences—researches in the field of sciences and letters, in particular mathematics and physics
National Institute of Sciences and Arts—to perfect sciences and arts by constant research
International Society of Electricians—by means of money or instruments to promote work on research and scientific undertakings
Western Association of Technical Chemists and Metallurgists—to encourage research in the metallurgy of precious and rare metals

Certain societies are devoted either to the encouragement of research and inquiry in, or the material development of, certain sections of the country, as:

Missouri Historical Society—encouragement of historical research and inquiry, especially within the state of Missouri and the Mississippi Valley
Municipal Engineers of the City of New York—to further the material development of the City of New York
New York Historical Society—to discover, procure and preserve whatever may relate to the natural, civil, literary and ecclesiastical history of the United States in general and of the State of New York in particular
Society of Municipal Engineers of the City of Philadelphia—to further the material development of the City of Philadelphia

The note of service to the public is struck by a few societies and though doubtless all aim to do this, nevertheless the following think it wise to state so quite definitely:

American Institute of Architects—to make the profession of ever-increasing service to society
Institution of Mechanical Engineers—to give an impulse to inventions likely to be useful to members of the Institution and to the community at large
National Society for the Promotion of Industrial Education—to bring to public attention the importance of industrial education, to promote the establishment of institutions for industrial training
Oregon Society of Engineers—to organize engineering opinion in matters of public interest
Surveyors' Institution—to promote the general interests of the profession and to maintain and extend its usefulness for the public advantage
Society of Civil Engineers of France—to promote by the active assistance of its members, professional education among the workmen and foremen in the industries and shops
Royal Statistical Society—to collect, arrange, digest and publish facts illustrating the conditions and prospects of society in its material, social and moral relations

In a few of the societies' purposes there is a clause relating to the promoting of the interests of the members of the societies, for instance:

American Foundrymen's Association—the advancement of the interests of foundry operators
American Institute of Accountants—to safeguard the interests of public accountants
Michigan Electric Association—to foster and promote the common interests of its members
Mining Society of Nova Scotia—to mutually benefit and protect its members
French Society of Alumnae of the National School of Mines at Saint Etienne—to secure for each member a position in the industry

With many, libraries and their maintenance are considered of sufficient importance to be mentioned in the statement of their purposes, and here we have the following list:

American Institute of Mining Engineers
The American Society of Mechanical Engineers
California Academy of Sciences
Franklin Institute of the State of Pennsylvania
Insurance Society of New York
United Engineering Society

Employment of their members and the rendering of financial assistance, when possible, are other laudable motives displayed by the following societies:

French Society of Alumnae of the National School of Mines at Saint Etienne—to create an assistance fund permitting pecuniary assistance to those who may need it and to secure for each one of them a position in the industry
Society of Architects Holding Diplomas from the French Government—to come to the assistance of the members by granting pensions and financial assistance
Society of Civil Engineers of France—to search for and announce to its members vacant positions to which they might aspire and to assist temporarily within the limits of its resources those of its members who may be in need of such assistance

Two entirely different elements are introduced in connection with publicity and legislation and here we find:

American Association of Engineers—supervising proposed legislation affecting the engineering profession, and taking any action necessary or advisable to safeguard the profession's welfare; promulgating the Association's ideas through proper publicity
American Bar Association—to promote the administration of justice and uniformity of legislation throughout the union

The improvement of the professional education of their members is another aim expressed by the *American Institute of Accountants*, and by the *Insurance Society of New York*.

The *Mining and Metallurgical Society of America* has for one of its objects the conservation of mineral resources, while the *American Society of Engineering Contractors* stands for "the elimination of those practices and abuses that now exist in the engineering and contracting business."

REPORT OF THE COMMITTEE ON WEIGHTS AND MEASURES OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS[1]

To the Council of the American Society of Mechanical Engineers:

In its study of the extent of use of the metric system, your committee secured copies of a report entitled, "The Metric System in Export Trade," made by Mr. F. A. Halsey to the American Institute of Weights and Measures, an organization having for its main objects the maintenance and improvement of the English system of weights and measures.

This report is based upon more than fourteen hundred answers to a questionnaire which was sent to several thousand manufacturing concerns in the United States, some or all of whose product is shipped to countries which are supposed to use the metric system.

It is the only instance which we have been able to find where an earnest and sincere effort has been made to get at the actual facts with respect to the use of the metric system in export trade from the United States. While a great deal has appeared in print on this subject, nearly all of it was based on conjecture or limited knowledge. This report, as stated, gives the actual facts reported by more than fourteen hundred manufacturers.

The information contained is of such great interest and value to all who are studying this question with a desire to get at the truth, that we feel that our Society would be rendering a real service if the essential facts of this report as deduced from the replies to the questionnaire were presented to the membership. Your committee, therefore, offers herewith a comprehensive abstract of this report which comprises a careful summary of the replies received and the conclusions to be drawn from them.

Respectfully submitted,

L. D. Burlingame, *Chairman*
E. M. Herr
F. A. Halsey
J. Sellers Bancroft
A. L. De Leeuw
Committee on Weights and Measures

In view of the thoroughness of the inquiry, this report may fairly be regarded as a census of the use of the metric system in this country.

The inquiry took the form of a questionnaire, which was sent to the following lists of manufacturers:

1 Our own members, of whom many are exporters

2 The members of the American Manufacturers Export Association

3 Those included in a card list of exporting manufacturers compiled by the American Manufacturers Export Association.

The total number of those to whom questionnaires were sent exceeded 6000. No selections were made from these lists, the questionnaires being sent to every name upon them. The number of countable replies received was 1445.[2]

The promise of a copy of our report to each one who answered the questionnaire (see form letter below) brought many replies from those who added to their questionnaires that they did no export business, or that their export business was confined to English-speaking countries. Such questionnaires, having no significance, were not counted.[1]

A considerable number of replies were received, filled out in due and proper form, except that they were unsigned. Such questionnaires were not counted, except those unsigned questionnaires enclosed with signed letters or in envelopes carrying printed firm or corporate names and addresses.

A few replies were received from exporting merchants but, since it is physically impossible for a merchant to record on one sheet the practice in producing the numerous products in which he deals, such replies were not counted. This was foreseen and provided for in the first paragraph of the form letter, by which the inquiry was restricted to exporting manufacturers.

The questionnaire was sent out with the form letter and immediately follows it.

Dear Sirs:

In accordance with the purpose of the Constitution of this Institute to investigate the usage of weights and measures in their various applications, we enclose to you, and to a large number of exporting American manufacturers, a questionnaire intended to discover at first hand how much truth there may be in the assertion that this country should adopt the metric system if it expects to succeed in the cultivation of foreign markets.

Such an inquiry is obviously a necessary preliminary to the proper consideration of a change in our fundamental units of weight and measure, but, until now, no effort has been made in any quarter to conduct one. You will, we are sure, agree that it is a matter of first importance and we believe you will be glad to assist us by filling out and returning the blanks of the questionnaire.

This questionnaire represents but a small part of the investigations which we have in progress, and your coöperation is of even greater importance than here appears.

In order that you may retain a copy for your files in convenient form, the blanks are enclosed in duplicate.

When completed and published a copy of our report will be forwarded to all who show interest by supplying the asked for data.

Please answer whether you do or do not use the metric system. We want the facts on both sides.

Form Letter

——————1917.

American Institute of Weights and Measures,
20 Vesey Street, New York.

Gentlemen:

Referring to your inquiry regarding our experience with weights and measures in foreign trade, you will find that experience summarized below:

We have been engaged in foreign trade for .... years.

Our line of products consists of ....

1. In our factory work, and in order to adapt our goods to the needs of buyers in metric countries, we have found it desirable to abandon English measures and use, instead, metric measures for the various dimensions of our products to the following extent:

Not at all		Make a cross in the appropriate square.
Slightly		
Considerably		
Extensively		
Exclusively		

Exclusively is understood to mean the absence of all English

[1] Presented at the Spring Meeting, Worcester, Mass., June 1918, of The American Society of Mechanical Engineers. The report is here printed in abstract form. Copies of the complete report may be obtained in pamphlet form; price 15 cents to members; 30 cents to non-members.

[2] A list containing the names and addresses of the manufacturers who replied to the questionnaire and whose replies form the basis of this report may be obtained from the American Institute of Weights and Measures.

[1] From the standpoint of *export trade*, as distinguished from *export trade with metric countries*, these latter replies (which, of course, show no use of the metric system) should have been counted.

dimensions in the product—not a few metric dimensions in every shipment.

Remarks and Particulars

2. We have found it advisable to pack our goods for trade with metric countries in containers of metric dimensions or containing metric weights to the following extent:

Not at all	
Slightly	
Considerably	
Extensively	
Exclusively	

Make a cross in the appropriate square.

Remarks and Particulars

3. In our literature for and correspondence with metric countries, we have found it advisable to give information regarding weights, output, capacities, over all dimensions, etc., in metric terms as follows:

Not at all	
Slightly	
Considerably	
Extensively	
Exclusively	

Make a cross in the appropriate square.

Remarks and Particulars

Yours very truly,

The Questionnaire

Confusion Between the First and Second Questions

The first questionnaires sent out were addressed *Manager Export Department,* but this was soon found to have been a mistake. Export departments are very familiar with shipping methods, but frequently they know little of factory practice, and their footnotes under Remarks and Particulars and accompanying letters showed that the two were frequently confused.

The object of the first and second questions was to discriminate between production and shipping methods. This is a distinction not of place but of kind, but in numerous cases it was ignored because, the packing and shipping being frequently done in the factory, they were regarded as part of the factory work. In such cases, the use of the system in shipments was made to give an answer for its use in production, and in other cases the giving of metric equivalents of English dimensions in catalogs and correspondence and even the giving of prices in metric terms were made the bases of replies showing the use of the system, in production, *so stated on the same sheets.* Some of these replies were naive in their simplicity, showing that those replying had no conception of the industrial uses of weight and measure other than shipping weights and price units.

This tendency to confuse shipping and commercial with factory methods was discovered after about 5 per cent of the questionnaires had been sent out, and thereafter they were addressed *Attention of Factory Superintendent* and, to make still plainer the distinction between the first and other questions, the following rubber-stamp impression was added to each outgoing questionnaire alongside the first question:[1]

This question relates EXCLUSIVELY to factory methods and measurements.

It has nothing to do with price units, sizes or weights of parcels or sales methods for which see other side.

[1] To further clear up any possible chance of misunderstanding in the replies, five other form letters were eventually sent out covering points which it was suspected that the writers had not fully understood.

Incomplete Answers

A considerable number of questionnaires were received in which but one or two answers were given. Examination showed that most of the answers given were in the affirmative; that is, they showed a greater or less use of the metric system. There is no reason why every return should not have included answers to all three questions. Every exporting manufacturer does or does not use the metric system in the three ways specified, and when replies were received, showing two affirmative answers with the other one blank, two explanations were possible. The first one was that the signer of the questionnaire had placed crosses for those uses of the system which he knew about and omitted the one with which he was not familiar, and the other was that the answers covered those cases in which the system is used, but passed over those in which it is not used, or, in other words, that in such cases no answer is equivalent to a negative answer.

The studiously non-partisan character of our form letters and questionnaire led many to believe that we are supporting the metric system, for which supposed activity we received both compliments and protests. But one letter of the opposite kind was received against many showing this impression, which led some to suppose we wanted only those replies that would support the metric propaganda.

Whatever the explanation, it was desirable to have the answers complete and another form letter was sent to many who failed to answer the first question.

The First Question

In our factory work, and in order to adapt our goods to the needs of buyers in metric countries, we have found it desirable to abandon English measures and use, instead, metric measures for the various dimensions of our products to the following extent:

This question is by far the most important of the three. When a manufacturer makes his products to the millimeter to the exclusion of the inch, he has, in truth, adopted the metric system and until he does that, he has not adopted it. The giving of catalog information in metric terms is a use of the metric system, but a use exactly comparable with the use of the Spanish language in catalogs for Spanish America and is no more the adoption of the metric system than the printing of such catalogs is the adoption of the Spanish language.

The fact that the commercial use of weights and measures is before us in every business transaction of every-day life leads many to assume the commercial use to be of paramount importance, and, indeed, to ignore the factory use. When we reflect that, excepting some foodstuffs, substantially everything we buy is made before it is sold, that factory measurements largely outnumber (frequently 100 and sometimes 1000 to 1) those which appear in sales transactions, that commercial measurements are usually the roughest approximations while factory measurements are often of the highest degree of refinement by precision measuring instruments developed for that purpose, we find that the primary, important measurements of civilization are those made in the production of commodities.

Replies to the first question are summarized in Table 1.

No Use of the Metric System in Production

The following extracts from letters make a suitable introduction to this phase of the subject.

The Addressograph Company (addressing machines, in export trade 12 years) write of only one request for goods to be

TABLE 1 SUMMARY OF REPLIES TO THE FIRST QUESTION

	Count of returns	Per cent
Not at all.	1188	82.2
Slightly	160	11.2
Considerably	29	2.0
Extensively	16	1.1
Exclusively	6	0.4
No reply to this question	46	3.1
Total	1445	100.00

marked in the metric system in the past twelve years.

The Babcock Printing Press Mfg. Co. (printing machinery; in export trade 30 years) write:

We consider the proposition of changing our system of weights and measures to the metric system as no more necessary or desirable than teaching the men in our shop the language of the country in which the machine is to be run.

The Berger Mfg. Co. (sheet-metal products; in export trade for 15 years) write:

We find that customers [in metric countries] are invariably acquainted with our system and that they are able to make conversions into our weights and measures the same as we do when an inquiry comes to us in metric.

The Black-Clawson Company (paper-mill machinery; in export trade 25 years) write:

We have had no trouble whatever using English measures.

The Boston Pressed Metal Company (metal stampings; in export trade 10 years) write:

France, Russia, Argentine, Brazil, Denmark, Australia and Canada use regular stock of inch sizes.

The Bristol Patent Leather Company (in export trade 12 years) write:

The largest leather-producing countries use the square foot as their basis, therefore, the square foot is a familiar unit even in countries using the metric system.

F. W. Brody & Co. (cottonseed products, in export trade "many" years) who reply Not at All to all of our questions, add:

And our exports the past season were approximately $1,000,000.

The Brown Folding Machine Company (paper-folding machinery, in export trade 20 years) write:

We cannot recall any instance where we have been asked to give anything but United States standard weights and measures.

The Brown Portable Conveying Machinery Company (portable conveying machinery; in export trade 6 years) write:

The foreign buyer buys from our standard sizes nearest to his approximate metric requirements.

The Cleveland Automatic Machine Company (machine tools) write:

We rarely have occasion to make up specifications using the metric system for abroad. We ship a vast amount of material to foreign countries.

The Collins Company (cutting tools; in export trade 70 years) write:

Our business is nine-tenths with foreign countries. We have no need whatever to use the metric system in our business.

Curtis & Marble Machine Co. (cloth-finishing machinery; in export trade 40 years) write:

Where the goods are measured by the roll or drum system, we use the regular yard circumference drum and then use compensating gears to reduce this to meters. In the South American trade there are four or five different lengths used, none of them metric and each a specific measurement for individual countries.

The Benjamin Eastwood Company (textile machinery) write:

There is no call for the metric system of weights and measures in building textile machinery for export.

The Chase Turbine Manufacturing Company (woodworking machinery; in export trade 40 years) write:

One customer has a scale attached to the machine to indicate width of opening. This scale is graduated according to the metric system.

The William J. Dines, Jr., Company (plantation machinery; in export trade 6 years) write:

When we receive orders for machinery, it is usual to receive a sketch showing the proposed installation and the dimensions are more often given in feet and inches than in the metric measures even from countries using the metric system.

The Dodge Steel Pulley Corporation (steel pulleys; in export trade 17 years) report exclusive use of English dimensions.

Eastman, Gardiner & Co. (building lumber; in export trade 12 years) write:

Last year we took up the matter with our agents in France, Belgium, Italy and England. They stated that although the metric system was used in some of the above countries, that in lumber, the buyers were so accustomed to using the English measure that it would be a great mistake to make any change in our method of figuring.

Fairbanks, Morse & Co. write:

We have been actively engaged in developing foreign trade for the past 15 years, and our experience touches practically every country in the world. The lines of goods that we manufacture and sell abroad are quite varied, embracing internal-combustion engines, steam, power, and centrifugal pumps, electrical dynamos and motors, railway supplies and windmills.

We are, of course, sending our goods to countries where the metric system is used, but we have not seen any necessity whatever for abandoning the English standard of weights and measures.

The Fawcus Machine Company (gears and gear drives; in export trade 16 years) write:

On one occasion we made some special machinery to drawings furnished by a customer in Spain on which metric dimensions were used. We readily transcribed them into English.

The Glasgow Iron Company (steel and iron plates, etc.) write:

Orders for our product come to us in feet and inches, and are so marked when shipped.

The R. P. Hazzard Company (men's shoes; in export trade 10 years) write:

We have never had called to our attention any metric system for designating sizes of boots and shoes.

The National Radiator Company (steam radiators, boilers and fittings) write:

Our foreign customers have taken our products just as we manufacture them for domestic trade.

The Penn Engineering Company (steam and water specialties, in export trade 18 years) write:

We have never used anything except English measures, nor found any need to change them at any time.

The Russell, Burdsall & Ward Bolt & Nut Co. (bolts, nuts, rivets and washers; in export trade 20 years) write:

We ship our goods to almost every country throughout the world and find that the English weights, measures, etc., are generally satisfactory.

William Sellers & Co. (machine tools and power-transmission machinery; in export trade 60 years) write:

Notwithstanding the large volume of foreign inquiry we receive, so little of it calls for adherence to the metric system as to be practically negligible.

The Walter A. Wood Mowing and Reaping Machine Company, who reply Not at All to all of our questions, say:

We do a large export trade in Scandinavia, France, Germany, Russia, Austria-Hungary and Roumania.

Manufacturers Who Replied that Metric Measures Were Unnecessary for Their Products

Representatives of some 570 different industries replied to the first question regarding the use of the metric system in the production of their goods for export by placing their crosses in the Not at All line.[1]

From the large number of chemical industries reporting it is seen that manufacturing, as distinguished from laboratory work, chemistry is conducted on the English system. The numerous electrical industries which follow the English system show that the prevailing impression that the electrical is a metric industry is unfounded.

Many of the industries from which replies were received, such as chemicals, agricultural machinery, mining machinery, etc., produce not one, but great lines of products. Such industries, however, are considered as single items, the number referring not to products, but to industries.

Partial Use of the Metric System in Production

The reports of partial use are, in some respects, the most instructive of all. From them, we learn that it is only in rare cases that the units of measure used in the production of a commodity have anything to do with its salability in any market, the calls for the metric system being always special and of no general application or significance.

For e ample, in substantially all lines of machinery, foreign purchasers of automobiles, electrical, mining, ice-making, agricultural machinery, etc., care no more about the units to which the parts of these machines are made than the reader cares about the English or metric units used in the construction of his own watch. The only exception to this law is found in about one-third of the reports for machine tools. Here the metric features called for are those few immediately concerned in measuring the products made on the machine.

Again, in the case of chemicals, it must be clear that the units used in the productions of the goods have nothing to do with the salability of the products. In steel and iron products—structural material, pipe, etc.—the preponderance of English-speaking countries in the production of these goods has made their products the standard of the world as is true, also, of automobile tires; while in textiles a letter of the American Printing Company saying that "practically all of our goods for export trade are measured in yards," shows the extent to which the yard is used as a price unit in the metric countries.

The most striking illustration is found in weighing and measuring instruments designed for weighing in metric units. In these instruments the construction remains strictly English, the only metric feature being the graduated dial or scale by which the indications are read; and in the case of recording instruments, these graduations are placed on ruled sheets of paper which are not even parts of the instruments.

[1] A list of the industries and the replies received in each is given in the complete report.

Representatives of the following industries reply to the first question by placing their crosses in the Slightly, Considerably or E clusively lines as indicated by the figures in parentheses.

Automobiles and automobile trucks: Not at all (22), Slightly (20), Considerably (2).

The use of the metric system in the automobile and automobile-truck industry to meet the needs of export trade is limited to speedometers, spark plugs, tires and wheel rims to suit the tires. Speedometers are graduated to read in kilometers just as, for Russia, they are graduated to read in versts. In both cases, we give the customer what he wants and one practice has as much and as little significance as the other.

It will be observed that most of the automobile companies who use the metric system at all place their crosses against Slightly for the use of the metric system for these items. The extent of this use is shown by the following extracts from letters.

The Cadillac Motor Car Company say:

Until a year ago millimeter-sized wheels and tires were shipped with cars to Australia, but our distributor there changed to inch sizes. Most South American countries take inch sizes, with the exception of Chile, which takes millimeter.

The Paige-Detroit Motor Car Company say:

At the present time, the demand for metric wheels, rims and tires is extremely limited. Since the first of the year, we have only shipped 6 cars so equipped.

The Dart Motor Car Company, Dodge Brothers, the Elwell-Parker Company, the Ford Motor Company, International Motor Company, Lexington Motor Company, and the Maxwell Motor Sales Corporation, all report the use of American-size tires in their trade.

Metric spark plugs are so called because of the metric screw thread by which they are secured in place, all their other dimensions being English. Such plugs, however, are not universal in metric countries. The Cole Motor Car Company say in reference to export trade:

We use the 7/8—18 S.A.E. standard spark plug.

The J. B. Crockett Company say:

The percentage of metric spark plugs against those of standard thread as used by ourselves which are exported is about two-thirds metric—the balance, 1/8, 1/2 inch and 7/8 inch, that is, omitting the regular Champion X Ford plugs. The greater portion of Ford spark plugs shipped into foreign countries are the same as the regular standard American used here.

The Paige-Detroit Motor Car Company say that requests for the metric spark plug are practically obsolete at present, and Dodge Brothers report annual shipments valued at $1,000,000 to metric countries, but all cars are furnished with standard English spark plugs.

Automobile crankshafts: Slightly (1). The Automobile Crankshaft Corporation (in export trade three years) who make this report, say:

About 60 per cent of crankshafts we are making for export are in English measurements, 20 per cent in English and metric (that is, some dimensions English and some metric) and 20 per cent in metric only.

Athletic goods: Not at all (1), Slightly (1).

Agricultural machinery: Not at all (9), Considerably (1), Slightly (1).

Abrasives and sharpening stones: Not at all (3), Slightly (1).

Ammunition: Not at all (1), Extensively (2).

Belting: Not at all (2), Slightly (4), Considerably (1), Extensively (1).

The Rossendale-Reddaway Belting and Hose Company who report Extensively, say:

We do not use it at all as far as the actual manufacturing is concerned. We do, however, receive many inquiries and orders from other countries in which they request length, breadth and thickness of belting according to the metric system, and in filling the orders, we supply them with the nearest measurements we have in feet and inches.

Brass and copper goods: Not at all (6), Slightly (2), Extensively (1). The Bridgeport Brass Company (in export trade 25 years), who report Slightly, say:

We have furnished during the last two or three years large quantities of brass disks for the manufacture of cartridge cases, the dimensions of which were specified in metric units. These metric units we simply translate into the corresponding English equivalents and proceeded with the order. We have made seamless tubes in a similar manner and several million copper bands for shrapnel.

Bolts, nuts and rivets: Not at all (4), Slightly (3). Boiler tubes: Not at all (1), Considerably (1). Ball bearings: Not at all (1), Slightly (1). Balls: Not at all (2), Considerably (1).

Brick: Slightly (1). Boiler tube cleaners: Considerably (1). The William B. Pierce Company (in export trade 19 years), who make this last report, say:

In countries using the metric system we merely use that system for turning and measuring the outside diameter of the machine.

Boat oars, hardwood dimension stock, etc.: Slightly (1).

Cutting tools: Not at all (14), Slightly (4), Considerably (5). The Cleveland Twist Drill Company (in export trade 30 years) who report Considerably, say that to France, Sweden, Italy and Spain their shipments are 90 per cent to 100 per cent metric. Shipments to Norway, Holland, Denmark and Russia are about 50 per cent English and 50 per cent metric. Shipments to Japan are about 90 per cent English and 10 per cent metric. Shipments to Central and South America are 95 per cent to 100 per cent English.

There are two types of cutting tools—those which by their own size determine the size of the work done by them (twist drills, reamers, taps, dies, milling cutters for gear teeth, etc.) and those which do not (most mechanics' hand tools). The replies showing the use of the metric system relate to the former type in all cases.

The remarks under weighing and measuring instruments below apply here almost without change. Sizing tools of millimeter dimensions are not made for use at home, but to sell for use abroad.

In 1916 a report on The Metric System in Export Trade was issued from the Bureau of Standards. Of thirty-three pages of illustrations of American metric products, twenty-seven show weighing and measuring instruments and sizing-cutting tools made for sale and use abroad, while three of the remaining six illustrations show lathes so arranged that others may cut metric screws when necessary, but every one of them fitted for cutting English screws as a primary function with makeshift translating gears to make possible the cutting of metric screws.

To those who do not understand, the illustrations make an impressive showing of the progress of the metric system; to those who do understand, they make an equally impressive showing to the contrary.

Many of these tools and instruments are of American invention. Metric countries learn of their merit and call for them. We adapt them to the needs of such customers by suitably spacing and numbering the divisions by which their indications are read.

Chemicals: Not at all (19), Slightly (1), Extensively (1). Chemical machinery: Extensively (1). The Werner & Pfleiderer Co., who report Extensively, say:

When originally starting here in this country, we took over a number of patterns and drawings in metric which we have used ever since.

Corsets: Not at all (1), Slightly (2), Considerably (1). Car wheels, chilled rolls, and roll-grinding machines: Not at all (2), Slightly (1). The Lobdell Car Wheel Company (in export trade nearly 50 years) who make this last report, say:

We occasionally get orders for chilled rolls for calendering paper to go abroad and the dimensions of the journals and necks are sometimes specified in millimeters. We have also had orders for a few wheels and axles with the metric sizes specified for the axle and hub dimensions.

Cotton duck: Not at all (2), Slightly (1). The Elm City Cotton Mills (in export trade 10 years) who make this last report, say:

We have shipped quite a bit of cotton duck to Cuba and there have been a few instances where they have asked for metric measurements. For the last few years probably 95 per cent of the shipments we have made have been billed and branded with the usual English measurements.

Clay-working machinery: Not at all (1), Slightly (1). The American Clay Machinery Company (in export trade 37 years), who make this last report, say that this use of the system refers only to dies and molds used in presses and other machines for making clay goods.

Candles, stearine, glycerine, etc.: Not at all (1), Slightly (1).

Drop forgings: Not at all (1), Slightly (2). The Armstrong Brothers Tool Company and the Billings & Spencer Co. who both report Slightly, say that this use of the system refers only to "openings in machine wrenches."

Electrical machinery: Not at all (14), Slightly (1). The Westinghouse Electric and Manufacturing Company (in export trade 20 years), who make this last report, say that metric requirements are given in only a small fraction of the business taken—too small to state in figures.

Elevators, escalators, conveying and hoisting machinery: Not at all (8), Slightly (1). Explosives: Not at all (1), Slightly (1). Electrical wires, cables and accessories: Extensively (1).

Firearms, sporting: Not at all (4), Considerably (1). The A. H. Fox Gun Company (in export trade 5 years), who make this last report, say:

About half of our foreign orders are received with the dimensions of the guns in the metric system.

Firearms, military: Not at all (2), Slightly (1). Fireclay products: Slightly (1).

Filters: Not at all (2), Slightly (1).

Glass, including plate, window, jars and bottles: Not at all (8), Slightly (2).

Ground-steel shafting: Slightly (1). The Cumberland Steel Company (in export trade 20 years), who make this report, say:

We do not think we have finished any metric sizes for two or three years, and the quantity we made at any time is very small—hardly worth considering.

Grinding wheels: Not at all (4), Slightly (1), Extensively

(1). The Abrasive Company (in export trade 17 years) who report Slightly, say:

The grinding wheels that we supply to countries using metric measure are according to English and metric measures. It would be difficult to give an approximate idea of the percentage of the two kinds of measurements used, but perhaps we would not be far wrong in specifying 3 per cent metric and 97 per cent English.

The Hampden Corundum Wheel Company (in export trade 32 years) say:

Customers frequently order in metric specifications, but we supply the nearest English equivalents to their entire satisfaction.

Gas, gasoline, and oil engines: Not at all (12), Slightly (1). Gas-engine specialties: Slightly (1). The Kokomo Electric Company (in export trade seven years) who make this last report, say:

Only in one article—a metric thread spark plug.

Hoisting machinery: Not at all (2), Slightly (1).

Hammers: Slightly (1). Fayette R. Plumb, Inc. (in export trade 30 years), says:

The only cases are a certain pattern of carpenters' hammer and a certain pattern of sledge hammer used in South America.

Handles for hand tools: Not at all (2), Slightly (1).

The Turner, Day & Woolworth Handle Co. (in export trade 30 years), who make this last report, say:

Under normal conditions, shipments to those countries in which millimeter measurements are used will run about 25 per cent against 75 per cent on which inches are used.

Ice machinery: Not at all (4), Slightly (1). The Vilter Mfg. Co. (in export trade 30 years), who make this last report, say:

We do not think we ever made any of our compressors to millimeter sizes, but have made pipes, fittings, etc., at times. [The ice machine is, essentially, a gas compressor.]

Insulated electric wire and cables: Slightly (1).

Ingot metals: Slightly (1).

Knit goods: Not at all (2), Slightly (1).

Locomotives: Not at all (1), Slightly (2), Considerably (1). The Davenport Locomotive Works (in export trade 10 years) who report Slightly, say:

Only for track gage of locomotives.

Leather goods: Not at all (1), Slightly (1). Lubricators: Not at all (4), Slightly (1). The Richards & Phoenix Co. (in export trade 6 years), who make this last report, say:

Whitworth pipe threads are usually called for.

Machine tools: Not at all (60), Slightly (32), Considerably (3).

Machine tools are the machines with which machine shops are equipped. On them all other machines of whatever kind and for whatever purpose are made and the dimensions of their parts determined. Here, if anywhere, the need of the adoption of the metric system in export trade would be imperative and the returns from this industry are hence the most instructive of all.

The returns show the greatest use of the metric system to be in this industry and it is in this industry that The American Institute of Weights and Measnres had its origin and has today among its members the greatest number of representatives, which is to say that those who have had the most experience with the system are also those who have organized to resist its further extension.

Some types of machine tool are fitted with attachments for indicating sizes and adjustments, and some are not. Such attachments, like weighing and measuring instruments for metric countries, are made to read in millimeters and frequently the graduations of these attachments are the only metric features of the machines. Thus we have drilling machines with indicators for the depth of the hole drilled reading in millimeters, but with no change in the machines. Since the circumferential speed of the cutting tools is an important thing to know, we also have cases in which tables are attached to the machines showing the speeds of different-sized drills at different rates of revolutions per minute in meters per second instead of feet per minute. We also have milling machines in which adjustments are made through the use of screws and graduated dials. In order that the indications may be made in millimeters, the screws (three in number) are cut to metric pitches and the dials graduated to read in millimeters with no other change in the machine.

Of a special class are lathes because of their important function in cutting screws, and this function has been a storm center of this controversy from the beginning. For this purpose lathes are fitted with lead, guide or master screws from which screws of other pitches are cut by the aid of combination or change gears.

How few metric countries call for any metric features of machine tools is shown by the following remarks by machine-tool builders. Except for lead and adjusting screws, which a few metric countries call for on some machines, the requirements are insignificant. About two-thirds of the replies show no metric features whatever to be asked for.

The Automatic Machine Company (automatic threading lathes; in export trade 12 years) say:

We furnish the various countries of Europe with our standard lead screw with the exception of France, Spain and Italy, to which three countries we furnish the lathes with metric lead screws.

Baker Brothers (keyway-cutting machines; in export trade 20 years) say:

We furnish some cutting tools in metric widths for keyseats, but the majority are furnished in English measurements even for metric countries.

The E. W. Bliss Company (metal-working machinery; in export trade 40 years) say:

We do not often find it necessary to make any part of our machines to metric measurements. Occasionally, some part, where tools already existing must fit, is required to be made to dimensions in millimeters.

The Cincinnati-Bickford Tool Company (drilling machines; in export trade "many" years) say:

We use metric speed and feed plates and give metric graduations on spindle sleeves or dial depth gages.

The Cincinnati Gear Cutting Machinery Co. (gear-cutting machines; in export trade 9 years) say:

For European countries we furnish a metric elevating screw for the work arbor and cutter arbor of metric diameter. All other dimensions are English.

The Cincinnati Milling Machine Company (milling machines; in export trade 20 years) say:

This applies to the feed screws which, for metric countries, are made so that the dial reads in millimeters instead of thousandths of an inch.

The Detrick & Harvey Machine Co. (planers, horizontal boring machines, gun lathes, etc.; in export trade 25 years) say:

Only in the matter of furnishing metric reading scales on certain machines. We have sold machinery in England, France, Germany,

Russia, Italy, Holland, Norway, Japan, South Africa, Chile, and other foreign countries.

The Gleason Works (gear-cutting machinery) say:

The only use we make of metric dimensions in our work is when we manufacture adjusting screws to metric standards to be used in conjunction with metric scales which show relative movements of parts of the machines.

The Lees-Bradner Company, Lodge & Shipley Machine Tool Co., The Kempsmith Manufacturing Company and the Springfield Machine Tool Company all report the use of metric units only in parts of articles for export to France.

The Norton Grinding Company (cylindrical grinding machines; in export trade 16 years) say:

There are four small parts of our grinding machines that we make to metric measurements for a few customers in some European countries.

The Rockford Drilling Machine Company (drilling machines; in export trade 17 years) say:

Metric dimensions are stamped on drilling-machine quills on machines for certain foreign countries.

Shortly after the beginning of the great war the *American Machinist* sent a commissioner (Mr. O. P. Hood) to South America. Mr. Hood's papers show that in the machine shops of South America—of which there are more than most people realize—39.3 per cent of the machine tools are American, 43.2 per cent are British and the remaining 17.5 per cent are German, Belgian and French. While South American shops have the world from which to buy, they choose machine tools made to English over those made to metric measures in the ratio of nearly 5 to 1.

Mechanical presses: Not at all (2), Slightly (1).

Magnetos: Not at all (1), Slightly (1). Machinery and equipment pertaining to the meat industry: Slightly (1).

Optical goods: Not at all (5), Slightly (2), Considerably (2), Extensively (1).

The use of the metric system in optical work applies only to the grinding of lenses, the mechanical parts of cameras, microscopes, etc., being made to the English system. This system was not adopted for the benefit of export trade, as is shown by the following from the Eastman Kodak Company:

It is customary in this work to use the metric system of measurement, probably because the practice in U. S. A. followed foreign practice where lens optics were first perfected.

Lens manufacture is one of many examples of the manner in which an industry, when transferred from one country to another, carries with it the units of measurement on which it was developed.

Another illustration is found in shoe machinery. The United Shoe Machinery Company write:

Our company established factories in England, France, Germany and Austria, and have exported goods and maintained subsidiary companies or branch offices in practically all of the countries of South America.

In order to maintain uniformity in such machines as we manufacture both at home and abroad, the English system of measurements is used in all countries so that if necessary machines and parts may be supplied from one country to another.

Another illustration is found in machinery and appliances for the chemical trade, regarding which the Werner and Pfleiderer Company write:

When originally starting here in this country, we took over a number of patterns and drawings in metric which we have used ever since.

Again, the Whitehead torpedo carried the English inch from England to Austria; as, again, steel balls carried it from the United States to Germany. The methods of wholesale precision manufacture of balls were developed in this country and taken to Germany where the customary practice today is to make steel balls to inch dimensions—German formulæ for the carrying capacity of ball bearings containing a factor for the diameter of the balls in English inches.

In the manufacture of silk fabrics, among Western nations France early gained the leading position and, as a result, the French system of numbering silk based on the denier (a weight) and the aune (a unit of length) became not only the silk standard of France, but of all countries, and is today the world standard for silk. In like manner, the early dominance of England in the cotton trade has made the English system of numbering cotton yarn based on the yard and pound the standard of the world, the only exception being France.

Equally striking is the establishment as world standards of the English standards for numbering linen and jute yarn.

But the most impressive example of the spread of standards of measurement as a result of industrial development is presented by Russia, whose system of linear measurements is based on the English inch and foot as a result of the visit of Peter the Great to England about 1701. The Russian duim is the English inch; the Russian foot is the English foot; the arshine is 28 inches; the sagene is 7, and the verst is 3500 English feet. All these are standards that will survive revolutions and invasions and are, with the language, the most stable of the country's institutions.

Oil-mill machinery: Slightly (1).

Oilless bearings: Slightly (1).

Oxygen apparatus: Extensively (1).

Power-transmission machinery: Not at all (8), Slightly (3). The Dodge Manufacturing Company (in export trade for 25 years) who make one of these reports, say:

Probably 99 per cent of our export production is made on English measurements and weights—that is, inches, feet and pounds.

The Standard Pressed Steel Company (in e port trade 10 to 12 years) find it necessary to babbitt the bearings in the shaft hangers to a diameter corresponding to shafting of millimeter diameter in use in some foreign countries.

Perforated metals: Slightly (3). The Harrington and King Perforating Company (in export trade "many" years), say:

On receipt of an order it (the metric system) is changed to the English system and thus put through the factory with a few exceptions. We often use the metric system for specifying the size of perforations in our own factory and to both foreign and domestic customers.

Pipe: Not at all (8), Extensively (1). In this case, cast-iron pipe. Platinum: Extensively (1). Paper: Not at all (13), Considerably (1), Extensively (1).

Picture frames and moldings: Not at all (2), Slightly (1). The Indiana Moulding and Frame Company, who make the last report, say:

Very few orders received requiring lengths or sizes in meters.

Piping: Not at all (1), Slightly (1).

Rubber goods, including automobile tires, hose, etc.: Not at all (11), Slightly (9), Considerably (2), Extensively (1). The practice regarding automobile tires is given above under automobiles. The Boston Woven Hose and Rubber Company (in export trade 30 years), who report Slightly, say:

The manufacture of hose for countries using the metric system is identical with the process used for hose consumed in this country with the single exception that the hose is made of a definite number of meters long instead of feet.

The Electric Hose and Rubber Company (in export trade 12 years) report that about 2 per cent they export to metric countries are made to millimeters and the balance to English sizes.

The Goodyear Tire and Rubber Company who have been widely heralded as having "adopted" the metric system, say:

We are shipping tires made in both English and metric sizes to countries using the metric system. We estimate that somewhat less than 20 per cent of our total tire exports are made up of metric sizes. In addition, we are actually making partial use of the metric system in manufacturing practice.

Railway material: Not at all (2). Slightly (2).

Seamless steel tubing: Not at all (1). Slightly (2). The Elwood Ivins Tube Works (in export trade 20 years or more), who make one of these reports, say:

When any person orders tubing made by metric measure, we immediately translate it in decimals of an inch. We never bill our tubes in metric measure, billing them in decimals of an inch. It is not by any means frequent that we get orders by metric measure.

Steel and iron products: Not at all (1). Slightly (1). Considerably (2). Shackle bolts and auto accessories: Slightly (1). The Bowen Mfg. Co. (in export trade 22 years), who make this report, say:

On one occasion we had to make a lot of spring-shackle bolts having a metric thread at one end.

Sugar machinery: Not at all (8). Slightly (2). The Joubert & Goslin Machine and Foundry Co. (in export trade 12 years), who make one of these reports, say:

The only time that we are called upon to follow metric dimensions is where we furnish some repair parts or make some addition to a machine built in Europe.

Scientific instruments: Not at all (2). Slightly (1). Extensively (1). The Brown Instrument Company say:

We build instruments [pyrometers] using both the fahrenheit and the centigrade scales. In this country probably one out of every hundred orders calls for the centigrade range.

Semi-rare ores and their products: Slightly (1).

Steam and plumbing supplies: Not at all (4). Slightly (1). The John Simmons Company (in export trade 27 years) say:

Lengths of pipe in meters for some countries.

Safety fuse: Slightly (1). The Ensign Bickford Company (in export trade 50 years), who make this report, say:

For export to South America and certain other countries, we are often required to measure the length of the fuse as well as given dimensions and weights in metric units.

Shirts and collars: Not at all (2). Slightly (1). Surgical, dental and hospital equipment and supplies: Not at all (7). Slightly (1). Spark plugs: Not at all (1). Considerably (1). The New York & Brooklyn Auto Supply Co. say:

According to our experience 50 per cent are shipped in metric thread and the balance in American threads.

Textile machinery: Not at all (9). Slightly (1). J. E. Windle (in export trade "several" years) says:

We have had to make measuring dials register in metric measure on several machines we have exported the past few years.

Tractors: Not at all (4). Slightly (1). The Knox Motors Company (in export trade three years) say:

Metric-sized spark plugs are used in our cylinders on export shipments, also metric measure is used in some ball bearings.

Transmissions for marine explosive engines Slightly (1).

Tobacco: Not at all (7). Slightly (1).

Textiles: Not at all (13). Considerably (1).

Stay bolts: Slightly (1).

Tool holders: Slightly (1). The Western Tool and Manufacturing Company (in export trade 10 years) say that this refers to threading tools only.

Vulcanized fiber. Extensively (1).

Watches and watch cases: Not at all (5). Extensively (2). The metric system was not originally applied to American watch manufacture for the benefit of export trade, but because it was believed to be better adapted to the industry. The pioneer American (the Waltham) works adopted it at an early date and have continued it. Later, the Waterbury (now the Ingersoll) Works were fitted out by men from the Waltham Works who took the metric system with them, but all other American watch works conduct their operations on the English system.

A parallel example is found in steam-boiler injectors. This industry was imported from France by William Sellers & Co., who adopted and have continued the use of the metric system, but no competitor has followed their example, all other injector factories being conducted on the English system.

Another example is found in card-indexing and filing systems. The pioneer in this industry—The Library Bureau—was founded by Mr. Melville Dewey, who was a metric enthusiast and therefore adopted the metric system at the beginning. Competitors failed to follow the example of the Library Bureau, and that company has now abandoned the system.

The Library Bureau say:

Some years ago all attempt at working to metric sizes and bringing out new cases was abandoned and the old lines were duplicated with full dimensions.

Our draftsmen and mechanics failed to make any attempt to familiarize themselves with the metric system, but simply translated the metric dimensions into English inches or fractions thereof, and worked accordingly. I do recall, however, having known one man connected with Library Bureau in former days who was inclined to brag that he had mastered the metric system sufficiently so that he could actually think in it as well as he could in feet and inches, but I take it that his was a very rare case.

A fourth example is found in magnetos. The Ericsson Mfg. Co., who manufacture the Berling magneto, write:

As a matter of fact, 10 years ago we used the metric measures in this plant exclusively, but owing to inability to get American mechanics who could use the metric system, we found it necessary to shift to the English measures and they are now used exclusively by us both for our product for domestic and export manufacture.

A fifth example is found in the chemical industry of the Solvay Process Company, of which the drawings used in the construction of the first plant came from Belgium and were in the metric system. These units were abandoned for lack of workmen educated to use them. It should be added, however, that the Solvay Process Company have continued to use metric measures of weight and capacity.

Here are five examples of the attempted adoption of the metric system under the most favorable possible conditions, namely, at the beginning of an industry. In two of these cases, it has been abandoned outright, and in the third, abandoned for measures of length.[1] In the other two cases, it has been continued in the factories where it was introduced, but it has not spread to other factories which followed them in point of time.

Moreover, those who continue to use the system because they have established an industry upon it and find the same difficulty in changing from it that they would in changing from the English system, do not find the anticipated advantages.

[1] It is well known that the great difficulty of the change centers about the unit of length.

William Sellers & Co., who introduced the system in the manufacture of injectors, write:

Our experience with the metric system, extending over 50 years, does not encourage us to extend its use beyond the borders of the shop and the class of work for which it was originally started.

Weighing and measuring instruments including pressure gages, etc.: Slightly (8), Considerably (2). The H. W. Johns-Manville Company, who report Slightly, say:

When we have orders for speedometers for Latin countries or Germany, we make them to show kilometers and not miles. On orders from Russia, we make them to show Russian versts and not miles. The number of instruments sold to these countries is very, very small as compared with countries using miles.

The L. S. Starrett Company (in export trade 25 years), who report Considerably, say:

We estimate that not more than 5 per cent of our product is in the metric system.

The Richardson Scale Company (in export trade 12 years) who report Slightly, say:

Our scales being of the even arm type, our weights are all dead weights and it makes no difference what kind of weights are used. [Which is to say that the scales supplied to metric countries are *identical* with those supplied for home trade.]

American makers of weighing and measuring instruments have developed a large export trade and, for metric countries, they are, of course, to give their indications in metric units. For example, weighing scales of the dial type are made to read in kilograms, linear measuring instruments in millimeters and pressure gages in kilograms per square centimeter.

Worm gears and lead screws: Slightly (1).

Exclusive Use of the Metric System in Production

One representative of each of the following industries replies to the first question by placing his cross in the Exclusively line.

Carbon products (1), proprietary medicines (1), coin-operated machines and violin virtuoso instruments (1), piston-head packing rings for automobiles (1), drills, reamers and tools (1), adamite rolls and miscellaneous castings (1).

The Second Question

We have found it advisable to pack our goods for trade with metric countries in containers of metric dimensions or containing metric weights to the following extent:

The use of the metric system disclosed by the second question, while of trifling importance as compared with the use covered by the first question, is even more instructive as a means of showing the slight call for its adoption for the benefit of export trade.

If we pass over the use of the system in shipments due to the fact that several foreign governments compel its use for customs purposes, the conclusion is forced upon us that, were this government support withdrawn and the system left to stand or fall by its merits, this commercial use of it would practically disappear from our export trade. Three producers of food products report slight use of metric containers (two of them for lard only), one reports considerable use of such containers, and one extensive, if we include corn products which are partly food products.

The second question was intended to cover those goods which are shipped in tin cans, pasteboard boxes and other containers of definite metric weight or capacity.

Replies immediately began to come in with crosses opposite Slightly, Considerably, Extensively and even Exclusively, but with remarks added in footnotes or accompanying letters that the practice consisted only in marking weights in kilograms on shipping cases, and bills of lading to meet the requirements of foreign customs departments and consular invoices or of customers who called attention to the requirements.

This use of the metric system is on an entirely different basis from the use of metric containers. Metric containers are used because of a commercial need, but this use of the system represents a case in which the laws of other countries reach into our own.

Putting a machine in a box, weighing the box in pounds and then stenciling the equivalent weight on the box in kilograms does not make it a metric container. To clear up this point the following rubber-stamp impression was added to outgoing questionnaires, alongside the second question:

If this use of the metric system consists of nothing more than giving weights of shipments in kilograms to meet Customs and Consular Invoice regulations, that fact should be noted under Remarks and Particulars.

Following is a summary of the replies to the second question:

TABLE 2 SUMMARY OF REPLIES TO THE SECOND QUESTION

	Count of returns	Per cent
Not at all	746	51.6
Slightly	24	1.7
Considerably	16	1.1
Extensively	13	0.9
Exclusively	1	Negligible
Give metric weights and, in a few cases, dimensions on shipping cases and bills of lading	546	37.9
No reply to this question	99	6.8
Total	1445	100.00

Certain classes of goods cannot possibly be shipped in tin cans, pasteboard boxes or other metric containers. Those which obviously belong in this class are as follows:

Slightly: Automobile trucks (1), Elevating machines (1), Pumps (1), Automobile accessories (1), Oil-mill machinery (1), Rock-crushing machinery (1), Oil-well supplies (1), Gas engines (1), Wrenches (1), Belting (1), Oiled clothing (1), Counting Machines (1), Cotton goods (1), Shirts and collars (1), Steel castings, wheels and springs (1). Total (15).

Considerably: Grain-cleaning machines (1), Electrical machinery (1), Chains (1), Mining machinery (1), Ice-making machinery (1), Automobile tires (1), Machine tools (1), Fertilizer machines (1), Bolts, nuts, and rivets (1). Total (9).

Extensively: Cast-iron pipe (1), Automobile tires (1), Paper (1), Cotton duck (1), Athletic goods (1), Gas meters (1). Total (6).

Exclusively: Machinery pertaining to the meat industry (1).

There remain the following industries which are here credited with the use of metric containers.

Slightly: Food products (3) (in two cases, lard only), Photographic apparatus, materials and supplies (1), Tape measures (1), Petroleum products (1), Tobacco products (1), Rubber goods (1), Zinc products (1). Total (9).

Considerably: Food products (1), Scientific apparatus (1), Flour and feed (1), Candles, stearine and glycerine (1), Varnishes, etc. (1), Lubricants (1), Lithopone (1). Total (7).

Extensively: Corn products (1), Belt preservatives (1), Chemicals (2), Candles, stearine and oil (1), Radium, vanadium and uranium (1), Products not named (1). Total (7).

Exclusively: None.

Put in tabular form, we have the following figures for those who may be credited with the use of metric containers, although some of them are very, very doubtful:

	Count of returns	Per cent
Slightly	9	0.6
Considerably	7	0.49
Extensively	7	0.49
Exclusively	0	0.0
Total	23	1.58

Repeatedly, in these papers such expressions as "to South America only," or "to certain South American countries" appear, with several special references to Chile as the most insistent of all countries in this matter. A few follow the practice when shipping to some European countries, but the requirement that bills of lading and weights of parcels shall be given in metric terms appears to be confined to South American, and, perhaps, Central American countries.

Replies to the number of 106 place the cross for the second question in the Not at All line, and follow this under Remarks and Particulars with the statement that they make out shipping documents and give weights of shipping parcels in metric units. Such replies are clearly a discrimination between metric containers and the giving of weights of shipments in metric terms, and, in the intended meaning of the second question, should be included in the Not at All replies. This, however, has not been done, all such replies being included in the classification of those who give metric weights on shipping cases and bills of lading.

The questionnaire was not framed to bring out the effect of the laws of foreign countries on shipping methods, and, had it been so framed, no definite summary of the facts could have been obtained because the extent of this use of metric units in the case of any shipper depends upon the countries to which he makes shipments. However, many remarks upon the papers throw light upon this phase of the subject. Of these, the following are typical examples:

In a small part of our shipments, we find it necessary to give weights in kilograms. (In export trade 10 years.)

In some instances we have had to make crates with metric dimensions and weights, and have given metric dimensions on invoices. (15 years.)

We sometimes mark tags and boxes with the metric system.

Possibly 2 per cent of the export shipments. (10 to 15 years.)

This is not required on more than 10 per cent of our export shipments. (25 years.)

In some instances we have been requested to put the weights in the metric system as well as our own. (135 years.)

Occasionally, besides the English net and gross weights, we are requested also to give the kilos. (9 years.)

Sometimes asked to give all particulars of weights and measurements in metric figures. (60 years.)

For customs purposes in a very few instances. (12 years.)

Occasionally we have a request to give size of crate and weight of shipment in advance in the metric system. (15 years.)

Applies to about 1 per cent of our shipments. (20 years.)

Occasionally requested to give not only the weights in kilos, but also the metric measurements of the packages. (10 years.)

This applies to dimensions of packing cases which all countries accept from us in cubic feet and cubic inches. (10 years.)

The request for use of the metric system is not general or universal from all our customers in any one country. Some customers require it, while others in the same country do not. (30 years.)

Ship both English and metric containers to the same countries. (Almost a century.)

Have several times shown metric dimensions, weights, etc., on invoices and cases. (20 years.)

Occasionally give weights of shipments in kilograms. (30 years.)

Many more similar quotations could be given, but the above are sufficient.

The Third Question

In our literature for, and correspondence with, metric countries, we have found it advisable to give information regarding weights, output, capacities, over all dimensions, etc., in metric terms as follows:

Following is a summary of the replies to the third question:

TABLE 3 SUMMARY OF REPLIES TO THE THIRD QUESTION

	Count of returns	Per cent
Not at all	835	57.8
Slightly	279	19.3
Considerably	114	7.9
Extensively	78	5.4
Exclusively	38	2.6
No answer to this question	101	7.0
Total	1445	100.00

The use of the system covered by the third question involves the case of machinery, no more than the giving of capacities, weights and overall dimensions in metric equivalents; in the case of structural materials, the giving of weights in kilograms per meter instead of pounds per yard with leading dimensions of sections in approximate metric equivalents; and in other cases the giving of prices per kilogram or per liter instead of per pound or per gallon.

Why do but 42 per cent of our exporting manufacturers find occasion to make any use of the system and but 8 per cent of them to make extensive or exclusive use of it in this simple way? Because buyers in other countries understand our units precisely as we understand theirs—but better.

Conclusion

The conclusion is that the export trade of the United States is conducted by the English system. From Table 1 we learn that 82 per cent of our exporters to metric countries use the metric system not at all in production, while 14 per cent use it partially and in ways that, when explained, are inconsequential; and 0.4 per cent really use it exclusively.

In the commercial use of the system the results are equally striking. By the supplementary table under the second question we find that 1.6 per cent of our exporters thus use the system in response to a commercial need, *not one* exclusively, and, while 38 per cent make some use of it in shipments because compelled to do so by the laws of foreign countries, these uses, in the light of the extracts from letters in reply to the second question, are unimportant and show that the influence of such laws when confronted with the customs of commerce is slight.

APPENDIX

Since this Report was prepared, information has been received from England regarding the outcome of the metric agitation in Great Britain. In 1916 the British Government appointed a Committee on Commercial and Industrial Policy After the War, a copy of whose official Report to Parliament has been received. This Report deals with many phases of Great Britain's future industrial policy, Chapter X being devoted to Weights and Measures. From this Chapter, the following brief extracts are made:

Having given very full consideration to the subject, we are unable to recommend the compulsory adoption of the metric system in this country.

In our opinion, it is absolutely certain that the anticipated uniformity could not be obtained for a very long period, if ever.

There is, further, the serious objection that if we induced the above-mentioned countries to change over to the metric system, we should be surrendering to Germany the advantage which our manufacturers now enjoy over here, both in their markets and our own.

We are informed that even in France, which has made the metric system nominally compulsory for more than half a century, the "pouce" (or inch) is used in textile manufacture and numerous local measures still survive.

In referring to these considerations, we have to point out that there is no unanimity even as to the theoretical merits of the metric system as compared with our own. The practical argument that its adoption is desirable in order to secure uniformity in the markets of the world has been shown to be unfounded. We are not satisfied by any evidence which has been brought before us that trade has actually been lost to this country owing to the fact that the use of the metric system is not compulsory.

But to attempt to make the use of the system universal and obligatory in this country would cause great loss and confusion at a particularly inopportune moment for the sake of distant and doubtful advantages. We are convinced that, so far from assisting in the reëstablishment of British trade after the war, such a measure would seriously hamper it.

As regards the educational advantages claimed for the change, we have been referred to a statement quoted by the Select Committee of 1895 that no less than one year's school time would be saved if the metric system were taught in the place of that now in use. The information which we have received does not support that statement, and even if it were well founded, it must be remembered that for at least a generation, children would have to learn both the new and the old measures and how to convert from one to the other.

It is often popularly supposed that the introduction of the metric system would render possible the immediate sweeping away of many complicated and varying weights and measures. As we have already indicated, this belief is, in our opinion, wholly fallacious.

We are not convinced that the metric system is, upon the whole, even theoretically superior to the British system, and we are satisfied that the practical objections to the proposed change are such as decisively to outweigh any advantages which are claimed for it.

It is to be noted, moreover, that while in an Appendix to the Report several members of the Committee, which consists of nineteen members, file reservations regarding certain items, there is no reservation regarding the Chapter on Weights and Measures. In other words, the Report, so far as this Chapter is concerned, is unanimous.

The American Institute of Weights and Measures has several members in Great Britain through whom this Report has been transmitted. Letters from these members point out that in England this Report is looked upon as concluding the discussion and ending the controversy.

LABOR TURNOVER MEETING OF NEW YORK SECTION

A WELL-ATTENDED meeting of the New York Section of The American Society of Mechanical Engineers was held at the Engineering Societies Building, New York City, on Tuesday evening, May 21, 1918, to discuss the timely subject of Labor Turnover, George R. Woods acting as chairman.

The first speaker, James J. Pearson,[1] explained the British system of zoning the country for munition orders. All factories, he said, were either registered or not; i. e., if they had voluntarily offered their services to the Government and had been accepted they became registered and were kept busy on Government work. The country was divided into areas and the Government was represented in each area by an engineer, secretary and staff, and by an employment office. All workmen were listed and were either W. M. V. (Workmen Munition Volunteers) or not; in the first case they could be sent to any part of the country where their particular services were most required. Further, each workman was classified as A, B or C, according to his fitness. The labor unions had sidestepped their internal grievances and coöperated with the Government in meeting the needs of the times. The speaker was of the belief that the present labor troubles in England were essentially local in character and quoted several instances attesting the patriotism and determination of the people in general who applied their whole energy to increase the output of munitions. During an air raid over Bolton, which resulted in the death of about 130 workmen, the women workers stuck to their jobs in the factories while their men folk were facing murder and sudden death outside.

Orrin W. Sanderson[2] complained of the excess to which discussion on labor turnover was carried without seemingly coming to a definite estimation of its causes. His company employed over 20,000 men and operated 60 different departments, one of them being the Industrial Relations Department. The records of the employment office which were kept very elaborately and included the reasons prompting the men to leave, appeared to indicate that while there was no absolute remedy for labor turnover, it could be nevertheless considerably lessened by giving more consideration to the workmen and by curtailment in the advertising for help.

[1] Late of the British Ministry of Munitions.

[2] Director of Labor, B. F. Goodrich Co., Akron, Ohio. Assoc.-Mem. Am.Soc.M.E.

Dudley Kennedy[1] illustrated some of the difficulties his corporation had encountered from the labor standpoint. With a contract to build 120 ships in 18 months starting from November 1, they had succeeded in keeping an average of 25,000 men a day on duty by employing 130,000 men in six months. This excessive turnover of 420 per cent was to be explained in part by the lack of commodities and conveniences of the new place where the corporation had rapidly established itself. He emphasized the fact that there was more labor turned over in the United States than was necessary to man all of the industries of the country and that this must be checked. The practical step recently taken by the Government in appointing a labor dictator to regulate wages would help toward keeping them at a reasonable level so that there would not be an incentive for a man to change from one job to another.

H. F. J. Porter[2] dwelt on the necessity for organization by a group of men before it could have dealings with any one. Therefore, he concluded, if two groups were properly organized, one on the part of the employer to devote its energies in looking after the conditions of labor, and the other on the part of the employee to bring workmen into a condition of efficiency, it would be possible for these two to coöperate in improving labor turnover by considering the suggestions or grievances of the laborers and discussing them through representatives with the management.

[1] With American International Shipbuilding Corporation, in charge of shipbuilding plant at Hog Island.

[2] Consulting Industrial Engineer, 200 Fifth Ave., New York, N. Y. Mem.Am.Soc.M.E.

John Calder[1] summarized the reasons why employees left after short periods and the motives which prompted the employers to release or dismiss them. Incompetency, unwillingness, etc., were plausible causes for dismissing a workman, and yet in some cases they might arise from conditions which it would be easy to remedy, such as failure on the part of the employer to teach beginners. Outside of these reasons, however, there were two others more important in causing labor turnover, namely, draft selection and competition of manufacturers. The present military necessities had developed an undesirable state regarding the classification of the drafted men and some of these had been called from industrial occupations where they were rendering their best possible service to the country. Such a condition had existed in England and France at the beginning of the war and had created there a present shortage of skilled laborers, many of whom had been disabled in the fields of battle. His own experience in building up a force of 1000 employees at short notice had led him to believe that a great deal of good could be accomplished and much future trouble avoided by maintaining friendly relations with the local and district draft boards, who had no time to visualize the situation and would be greatly assisted by any information regarding the needs of the industries in their district.

Capt. Boyd Fisher[2] told the audience of a six weeks' course for employment managers given at Rochester University and of his efforts to have this preliminary course given at other institutions. The plan was to select from among the men with from three to five years' industrial experience and a fairly complete high-school or college education those who had the temperament and personality required of an employment manager and give them this brief training. The Ordnance Department, the Quartermaster's Department, the Navy Department, the United States Fleet Corporation, the Department of Labor, and the Educational Committee of the General staff, had all combined on this program.

L. D. Burlingame[3] presented a record of the results obtained by his company during the sixteen months that they had hired women in their shops. The record showed that during each month of this period the hirings were greater than the number leaving, the opposite being the case with the men. The comparison of turnover between the two sexes was made by obtaining for each the number hired per *job made vacant*. Thus, for employees averaging $1\frac{1}{2}$ months in service, the same job would have to be supplied eight times, and if there were 800 who had left with that average service, they would represent but 100 jobs made vacant. In this manner it was found that during the year 1917 but 1.5 women were employed for each job vacant, the record for the whole shop, including men, being 2.2 hired per job vacant. During the first four months of the present year these figures were 1.8 and 2.6, respectively. While on the basis of those leaving a larger percentage of women than of men had so far been discharged this year, on the basis of those entering the figures were reversed, that is, fewer of the women hired had been discharged in proportion, this being in the ratio of 15.6 per cent men to 11.8 per cent women. During 1917, 23 per cent of the men were discharged and only 11 per cent of the women. Among those leaving voluntarily the percentage of women leaving was greater than among men. It should be remarked, however, that night work, in which men only were engaged, was distasteful and many men left because they objected to such work. These investigations indicated that an important asset in reducing turnover consisted in providing for the convenience of employees in securing homes with comfortable surroundings. Another important consideration was the relation of foremen and fellow-workmen, as this had very much to do with a man's contentment and efficiency in his place of employment. As to the class of girls who could be successful in work of the character here referred to, it was found that those who had had previous experience in employment were far more likely to become permanent and satisfied employees than those who came directly from homes and had had no background of training.

H. E. Miles[1] classified labor turnover as a symptom of defective management. Just as a shop required a tool room, so it required a training room to produce the machinists who would manufacture the goods. In every factory in England that did war work they compelled them to adopt this training-room method, and in France the Ministry of Munitions had studied all of the ways that had been tried out in their three years of war, and more than a year ago they had required every factory in France employing 300 people or more to put in a training room to train the operators. Mr. Miles showed some slides of the work women were doing in the English factories. In tool rooms girls worked to 0.008 in. after sixty days' training. There was not a single piece in aeroplane work that was not being constructed by women, from the roughing of the crankshaft to the last bit of canvas or muslin put on the machine. Women were grinding to 0.0004 in. and were taught to do this in sixty days. He concluded that in view of the records of the English and French factories where labor turnover had been so greatly reduced by the establishment of a training room, it appeared that the employers of this country had a second obligation which they had been slow in recognizing.

Major E. N. Sanctuary[2] said that an officer had been appointed by the Secretary of War to coördinate all of the various branches of the department with the idea of reporting back to headquarters with any corrections or suggestions that would tend to eliminate the lack of coöperation which had existed in the past. This officer had suggested the proper utilization in the army of the large number of men who, on the final physical examination, had been found unable to go abroad with their divisions. Thus the conservation of man power would be effected through this new agency of the War Department working in connection with the War Service Exchange, the Committee on Education and Special Training, which was turning out 10,000 technical men every month, and other organizations that would help in delivering the right kind of men to the Government.

J. J. Swan[3] summarized the work done by the Committee on Classification of Personnel in the Army, which has, among other duties, the allocation of all skilled tradesmen throughout the Army. Following the example of England, where 70,000 shipbuilders, 15,000 machinists, and 40,000 coal miners had to be called from the fighting line after several months of training, some 7,000,000 cards, each one indicating a drafted man's trade and his first, second and third preferences as to the character of employment he would desire, were kept on file

with the Provost Marshal. When a call came for specialists the information was passed through to the local Boards and the tradesmen furnished. All the trades were analyzed and standardized, as well as the language throughout the entire Army, and the results printed in book form, alphabetically arranged, with an index covering the trade and a cable index for foreign communication. Similarly the Labor Department had undertaken the standardization of the munitions and shipbuilding trades. There would be specifications of the jobs and it was hoped that there would be ultimately a telegraphic clearance of labor conditions throughout the country as was the case with the Weather Bureau at this time, thus doing away with destructive competition. The question of wages would be taken care of automatically, the local price being determined by reference to local living conditions and other considerations. It was realized that it was impossible to draw the number of tradesmen required, and so the Government had instituted a series of trades schools, of which there would soon be one hundred equipped to give 100,000 men an eight weeks' training course.

J. B. Densmore[1] stated his belief that the fundamental difficulty the Government had had in handling the labor problem on a large scale, was lack of standardization of wages in both skilled and unskilled labor, lack of housing and local transportation, and the permission granted to all war industries to recruit their own labor. He assured the meeting on the part and with the authority of the Government that all of the competitive bidding and all of the independent labor recruiting by the war industries in this country was going to be stopped by the Government. There were a few preliminaries which must be taken care of before the whole machinery to handle the entire economic problem of labor in production could be arranged and announced. He felt that the only remedy for the present conditions was the standardization of wages and the establishment of a single labor-supply agency. It was shown by the records of the U. S. Employment Service that in places where it had had the exclusive labor supply, both skilled and unskilled, the labor turnover had been considerably reduced.

G. K. Parsons[2] prior to adjournment of the meeting, proposed a motion to the effect that the chairman appoint a committee to take immediate action to determine how the Society could render the greatest assistance in the solution of the problem of labor turnover. This motion was carried.

Suggestions to Aeronautical Inventors

It is announced by the Air Ministry of Great Britain that the Air Inventions Committee, formed about nine months ago, has now received and examined upward of 5000 inventions and suggestions relating to the air service and a statement has been issued to facilitate the work both of inventors and of the Committee. These suggestions are of equal interest to those in this country.

Owing to the conditions of the war, it is practically useless to submit inventions which would necessarily take a long period to develop; and, generally speaking, no very startling change in the present type of aircraft is anticipated, although improvements in parts and details are always possible, and may produce very important results.

The stage of development in construction which has now been reached is such that major improvements can only be expected from those possessing the requisite scientific and mechanical knowledge, skill and experience. Thus, radical changes in the shape of the wings of aeroplanes, the body, and the propellers are only possible after long and patient research carried out in aeronautical laboratories. Again, many inventors have forwarded proposals for helicopters and aircraft of a similar nature, which, if an efficient design could be produced, would possess certain advantages—but probably not to the extent at one time imagined. Others have suggested flapping wings and rotatory planes. Such schemes do not give any promise of being capable of development for use during this war.

As regards minor improvements, inventors should bear in mind that many details, such as turnbuckles, clips, etc., are now standardized, and that a change would only be justified by some very marked superiority. Safety devices for the machine and the pilot form a numerous class among the ideas submitted. The chief means suggested is the parachute, either applied by a harness to the pilot or directly attached to the machine. Those who have seen a passenger dropped by parachute from an aeroplane for exhibition purposes often fail to realize the conditions under which a parachute may have to be used as a safety appliance. The machine may be out of control, dropping at a velocity of 150 to 200 miles per hour, or spinning downward in flames. Many other safety devices such as automobile stabilizers, wind brakes, etc., have been proposed at various times. The additional weight incurred by the use of many of the suggested safety appliances must remain a very serious factor so long as war conditions prevail.

The engine is the heart of the aeroplane, and on its reliability depends the safety of the pilot. People acquainted only with motor-car engine practice sometimes do not realize the exacting conditions under which an aeroplane engine must work. The engine has to be capable of running for the whole of the time of flight at its maximum power. The lubrication and ignition must be perfect, and the engine must not become overheated. The rating applied to an aeroplane engine is its weight per horsepower. Engines which differ radically from present-day practice—such as the internal-combustion turbine—have small possibilities of being adopted, for successive design and reconstruction entailing probably several years' work are necessary before satisfactory results can be expected.

A subject intimately connected with the power plant is its noise. This noise constitutes one of the disadvantages of an aeroplane. For night flying a method by which it would be possible to hear from one aeroplane the approach of another would be of great advantage. The engine can be silenced without serious disadvantages, but the noise of the propeller and the hum of the wires are so great that silencing the engine is not sufficient to achieve the object in view.

Many hundreds of inventions and suggestions for inclinometers and instruments for straight flying and accurate bomb dropping have been investigated. Efficient and well-designed instruments for these purposes have been available for some time past, but it is quite possible that improved forms may still be produced, though it is scarcely likely that this can be done by any one who does not possess the scientific and mechanical knowledge required for an investigation of the nature involved. Some inventors of aeronautical instruments entirely disregard the action of centrifugal force upon pendulum and spirit-level devices. Many gyroscopic instruments have been proposed which show the inventors to possess insufficient knowledge of the correct application and limitations of a gyroscope. (*The Engineer*, vol. 126, no. 3262, July 5, 1918, p. 5)

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, Including Abstracts of Articles in Current Technical Periodicals

Tractor Tests at Salina, Kan.

At the National Tractor Farming Demonstration, held at Salina, Kan., July 25 to August 2, fifty tractors of nearly as many different makes were represented, and on the afternoon of the second day all started plowing a 240-acre field of winter-wheat land, some of the furrows being half a mile in length.

Belt, fuel-economy and drawbar-pull tests were conducted on many of the tractors exhibited by a committee of agricultural engineers selected from different state agricultural schools under the direction of J. B. Davidson, Mem.Am.Soc.M.E., professor of agricultural engineering at the University of California, but owing to objections of a number of tractor makers the results of these tests will not be made public until later.

Prior to the trials proper, however, the Parrett Tractor Company, of Chicago, Ill., started a 100-hour non-engine-stop plowing demonstration, the results of which have been given out. According to correspondence in the issue of *Automotive Industries* for August 8, the engine was run on kerosene for 103 hr. 19 min., during which period there were two stops totaling 5 min. 40 sec. due to sediment in the fuel line between the kerosene tank and the carburetor. It was necessary, however, to stop plowing for 13 hr. 28 min. on account of rain.

The tractor plowed for a total period of 80 hr. 42 min. 20 sec. and averaged 2.4 miles per hour while pulling its three 14-in. Oliver plows and plowing furrows averaging 6.36 in. in depth. Traveling at this speed it averaged 0.95 acre per hour. Kerosene was used exclusively as a fuel and the consumption was 1.99 gal. per hour, equivalent to 2.008 gal. per hour-acre, the unit of measurement adopted.

The consumption of lubricating oil was 1 gal. per 12 acres plowed, or 0.084 gal. per hour-acre. A water air cleaner was used and 7.5 gal. of water were required. Much of this water was found to enter the cylinders and serve in keeping down the temperature of the kerosene mixture. During the test 24.2 gal. of water were used in the radiator, or 0.314 gal. per hour-acre.

It was demonstrated during the test that plowing can be done at night as efficiently as in the daytime. The tractor was equipped with two Prest-O-Lite lamps which provided ample illumination for this purpose.

Report on Airplane Problems

The desire to enlist the inventive talent of America in the solution of aeroplane improvements has led to the issuance of a new bulletin by the Naval Consulting Board and the Engineering Council's War Committee of Technical Societies. The bulletin opens with a summary of the possibilities for improvement in aeroplane motive power, following which is a paper contributed by E. H. Sherbondy, of the U. S. Airplane Engineering Department, Bureau of Aircraft Production, War Department, in which are further discussed the various elements in which improvement may be expected.

For manufacturing reasons the Government finds it necessary to standardize motor design and is not now in a position to consider improved motors and systems of power. Such questions must be deferred until after the pressing needs of the hour have been met. The main problems are in the connection of the engine with the airplane and in the accessories which are necessary for the proper control of engine and plane. This includes the arrangements of pipe, wire, radiators, water connections, etc. New arrangements of tanks to make the plane more bullet-proof and to decrease the danger from fire should be studied.

The following figures for the efficiency of the aeroplane motor and propeller are of interest:

Energy of fuel delivered by engine shaft to propeller (Thermal efficiency). For the indicated hp. 30%. For the brake hp.	25%	
Energy consumed by engine friction	5	
Energy lost by cooling	30	
Energy escaping in exhaust (including that of unburned fuel)	40	
Total fuel contents	100	
Mechanical efficiency of propeller		75%
Net energy of fuel delivered by propeller and available for flight (0.75 × 0.25)		19%

The question of carburetion under the extremes of barometric and temperature conditions met with in flying are fully discussed. The richness of the carbureter mixture increases with the altitude and varies inversely as the square root of the ratio of barometric pressures. Temperature effects are relatively much smaller. Carbureter regulation for varying altitude, therefore, is of the utmost importance, and for this purpose at least two devices have already been produced, which are mentioned in the bulletin. Thermostatic apparatus for temperature control is less important and its value largely depends upon its freedom from complication.

In spite of the fact that the best talent of the country has been at work upon ignition problems, this is still a promising field for investigation. The difficulties met with in automobile practice are multiplied in the airplane, due in part to the higher compression. Good electrical conductors are poor heat conductors, and the high temperatures of the aeroplane motor cause a breaking down of the electrical insulating qualities of the spark plugs. At low engine power also there is the trouble from carbonization, which can be corrected by a better system of lubrication.

W. F. Durand, Mem.Am.Soc.M.E., Scientific Attaché, American Embassy, France, contributes a valuable chapter on Problems in Aeronautics, in which he discusses materials for airplane construction, ties and fastenings, supercharging engine, airplane instruments, etc. He draws attention to the possibility of a greater use of sheet metals, the chief advantage of which for wing surface or covering would be noninflammability and perhaps greater durability, but no wing covering can be considered which is markedly heavier than present forms for the same strength. Present coverings weigh from 4 to 4.5 oz. per square yard and have a tensile strength per inch of width of 70 to 80 lb. Any proposed substitute form must also give a smooth and continuous surface comparable with present forms. For the wing skeleton or frame, steel or aluminum alloys are attracting attention and seem to offer possibilities.

For fuselage construction steel or metal construction seems here also to offer hopeful possibilities, but under general limitations of equivalence regarding weight and strength com-

pared with wood. For ties the use of steel wire cable is standard and practically universal. This product is of very high grade, but there is room for improvement even here, both in the material employed, in the mode of laying up wires to form a complex tie member and in the form of section of such member. Joint fastenings are commonly made of sheet steel or sheet bronze. There is room for improvement expressed in terms of ease of manufacture, economical distribution of material, facility for attachment of wire or cable ties, and general adaptation to purpose.

The report closes with an extended bibliography.

Inventions and ideas should be submitted to Thomas Robins, secretary Naval Consulting Board, 15 Park Row, New York.

Machine Tools for Relining Guns

A recent development in the heavy-machine-tool situation is the announcement in the *Official Bulletin* of August 12 of the equipment which will be required for the Arsenal in France where the heavy guns of the American forces are to be relined. The relining of big guns is one of the biggest salvage operations in the war, as several times the value of the guns is saved by this process. The project for this relining plant is one of the largest undertaken by the Ordnance Department, and calls for the expenditure of between \$25,000,000 and \$30,000,000. The machine tools will cost between \$12,000,000 and \$15,000,000, and will consist of gun-boring lathes, engine lathes, rifling machines and grinders.

Among the equipment are to be nearly fifty 102-in. gun-boring lathes, which it is understood are to have reinforced-concrete frames, and a very large number of 84-in. lathes. In the building of the 102-in. lathes, a giant planer with a bed 500 ft. long, now under construction, will be used. It is stated that the bed is of such length that in its alignment a correction will have to be made to allow for the curvature of the earth's surface.

In addition to the machine-tool equipment required, the relining plant in France will include extensive shrinkage pits, traveling cranes of 240 tons capacity and an electrical generating plant of several thousand kilowatts capacity.

During the past few months, while the Ordnance Department has been outlining its requirements for heavy machine tools, the Society has assisted in every possible way. The subject was discussed at the Spring Meeting at Worcester, and President Main appointed the Society's Committee on Machine Shop Practice as a Committee on Heavy Machine Tools. Through its efforts, Mr. G. E. Merryweather, Mem.Am.Soc. M.E., was appointed by Mr. Baruch as "Machine Tool Dictator," and members of our Committee have been in consultation with him and with Government officers at intervals.

Grenades

The War Department authorizes the following:

More than 18,000 persons are employed in plants throughout the country in the manufacture of hand and rifle grenades. Hand grenades are now being produced at the rate of 2,000,000 a month, and within the next four months this rate will be doubled. Rifle grenades are being produced at the rate of about 1,000,000 a month, and this rate will be multiplied appreciably within the next six months.

The hand grenade may be of the defensive, the offensive or of the chemical type, of which latter there are two classes, phosphorus and gas.

The defensive grenade is the most powerful and the one generally used when tactical conditions permit, being thrown from cover at an advancing foe. It is about the same size and shape as a very large lemon with a body or shell of gray cast iron scored with deep grooves longitudinally and transversely to insure proper fragmentation when it explodes.

The offensive grenade differs from the defensive in that it depends entirely upon its explosive effect for its usefulness against the enemy and is generally used at shorter range, in offensive tactics, and when the grenadier is not necessarily under cover.

The phosphorus grenade has a barrel-shaped container of drawn sheet steel, about $3\frac{1}{2}$ in. long and $2\frac{1}{4}$ in. in diameter; to one end of this body is welded a steel collar or bushing, threaded on the inside. Into this collar is screwed a steel thimble which runs down into the center of the inside of the body of the grenade; this thimble is designed to prevent the phosphorus charge from coming into contact with the detonator and fuse. These last, together with the standard *bouchon* assembly of which they form a part, are screwed into the top of the thimble, which is threaded on the inside for this purpose. The grenade is painted gray when loaded (live).

The phosphorus grenade furnishes a shower of burning fragments of phosphorus as well as a cloud of dense white smoke, which can be used to repel an advancing attack, or if thrown during an advance, would both furnish a screen to conceal the advance and repel any enemy parties that might be in the open.

The gas grenade is in construction similar to the phosphorus grenade. It produces a low-lying cloud of dense white gas of an intensely irritating nature which may be classed as suffocating gas. It is used largely in what might be termed "mopping-up" the trench, cleaning out dug-outs by forcing the enemy into the open, or forcing him to wear a gas mask during the advance.

Rifle grenades are used to fill in the gap between the hand grenade and the light trench mortar. The type used by our army was designed by two Frenchmen, Vivens and Bessieres, and in their honor is called the V. B. rifle grenade. It is about $2\frac{1}{2}$ in. long, 2 in. in diameter and is fired from the discharger which fits over and is attached to the muzzle of the rifle in the same manner as a bayonet.

The regular rifle cartridge is used and the grenade is thrown from the discharger by the gases from the cartridge. The bullet fires the primer in passing through the central tube of the discharger. The flash is transmitted to the fuse, timed to burn eight seconds; and the fuse in turn fires the detonator, which bursts the walls of the detonator tube, and fires the main charge, thus exploding the body of the grenade. The normal range, when the rifle is aimed at 45 deg., is about 200 yd. (*Office of the Chief of Ordnance, General Administration Bureau, Information Section*, August 3, 1918)

Training of Women Begins

Toward the middle of July a two-months' course to train women for war work as employment managers was opened in the Case School of Applied Science, Cleveland, Ohio. The course is under the direction of the United States Ordnance Department through the Committee on Labor Relations of the Cleveland Chamber of Commerce, and Miss Mildred Chadsey, of Western Reserve University, is directing the work.

Applications for enrollment were received from 200 women from all sections of the country, from whom 50 were selected. Many of these are college graduates, some have been teachers, and their ages range from 25 years up.

The course consists of daytime factory work and evening classes. It differs materially from the one given for men under Government direction in Eastern schools because few of the women have any practical experience around a manufacturing plant.

The Cleveland manufacturers are heartily coöperating in the work and have willingly taken the students in their shops. The plants in which they are employed as regular operatives include the American Multigraph Co., Cleveland Hardware Co., Cleveland Metal Products Co., Hydraulic Pressed Steel Co., Osborn Mfg. Co., Standard Parts Co., Standard Tool Co., Warner & Swasey Co., Kirk-Latty Mfg. Co., and the Steel Products Co. (*The Iron Age*, vol. 102, no. 4, July 25, 1918, p. 199)

Photomicrographs of Changes in a Metal's Structure When Under Repeated Stresses

A striking feature of the annual meeting of the American Society for Testing Materials at Atlantic City in June, was the presentation by Prof. H. F. Moore, of the University of Illinois, Urbana, Ill., of a film of photomicrographs taken at various periods in the disintegration under repeated stresses of a wrought-iron test piece. It evoked so much interest that on request it was repeated the next day.

Though applied in this instance to wrought iron because of its large crystals, distinct markings and easy deformation under stress, it is not improbable that that principle will be later applied to steel, non-ferrous metals and other alloys. This may solve many problems now not fully understood and may lead to a scheme of heat treatment prolonging the life of certain steels and rendering them less liable to fatigue.

A. G. Eldredge, head of the Department of Photography, University of Illinois, perfected the optical and photographic arrangement whereby the taking of these photomicrographs was made possible. (*The Iron Age*, vol. 102, no. 6, August 8, 1918, pp. 323 and 325)

The Peat Industry

According to statistics of the United States Geological Survey, the peat industry has increased 420 per cent during the past ten years. The gross market value of the present output is $709,900; with proper productive methods it is expected that the price per ton can be reduced to $2.50 from $7.29, price in 1917, when there were but 18 producing plants distributed on the Atlantic Coast and in the Middle West.

Peat or muck consists of partly decayed vegetable remains that contain enough carbon to burn freely when dry, and ranges from the imperfectly decayed kind, of a light yellow color, to the thoroughly disintegrated jet-black type. In an undrained swamp it contains about 90 per cent of water, which must be reduced to 30 per cent before it can be used for fuel. No artificial drying process of commercial value has been developed.

This material has frequently been used as a source of charcoal and coke, of various by-products from coke retorts, as well as in making paper, substitutes for wood, etc.

Deposits that can be used for fuel are found throughout Minnesota, Wisconsin, Michigan, New York and the New England States, and in the northern parts of Iowa, Illinois, Indiana, Ohio, Pennsylvania and New Jersey; also on the Atlantic Coast from New Jersey to southern Florida and westward along the Gulf Coast to the Mexican boundary. (*Engineering News-Record*, July 25, 1918, p. 202)

Substitute for Silks Being Tested by War Department

Preliminary tests made at the Aberdeen proving grounds indicate that a chemically-treated cotton cloth can be used as a substitute for silk, and if found practicable the discovery will effect the double result of meeting a serious shortage in silk and bringing about a money saving in the ordnance program estimated at between $25,000,000 and $35,000,000.

At present millions of yards of silk are required in making the bags which contain the large powder charges used in the firing of heavy artillery. These bags are inserted in the gun immediately behind the projectile, and the firing of them gives the propelling force that hurls the projectile at the target. The propelling charge is, of course, entirely distinct from the charge within the projectile that explodes the missile after it reaches the target.

Heretofore silk has been depended upon for these bags for the reason that no other cloth material has been found that would meet the peculiar conditions required. It is essential that not a particle of the bag container shall remain after the gun is fired. Otherwise a smoldering piece of the fabric might cause a premature explosion when a new charge is inserted.

Early in the war Germany is understood to have used a chemically treated cotton as a substitute for silk, but has since been compelled by the diminishing cotton supply to resort to other substitutes. (*Journal of Commerce*, August 12, 1918, p. 9)

Cost of Operating Air Mail

The first report of the comparative cost of the operation and maintenance of the Air Mail Service shows that the airplanes used in this service have broken all records for economy of gas consumption.

The total of all operating expenses of nine airplanes covering flights aggregating 7234 miles, was $3682. The total consumption of gas representing 113 hours and 8 minutes of flying was 1377 gal, which is $32.50 per hour—something over 50 cents per mile. The total cost of gas was $405 in flying 7234 miles.

The best performance in flying was made by a Curtis J-N-4 machine, which flew 26 hours and 40 minutes at a cost of $28.01 an hour and covered 1719 miles at a cost of 43½ cents per mile. A plane equipped with a Hispano-Suiza 150-hp. engine used approximately 8 gallons of gas per hour, and a plane equipped with a 400-hp. Liberty motor used 17 gallons per hour. This shows 40 per cent less gas consumed than generally required for airplane engines of these sizes.

The calculation of operating cost includes departmental overhead charges, interest on investment, replacement of parts, deadhead time of mechanics, gas, lubricating oils, office force, motor cycles and trucks; rent, fuel, light and telephone; pay of pilots, hangar men and mechanics.

The average consumption of gas for the nine planes was 12 gallons per hour. (*Official Bulletin*, July 25, 1918, p. 5)

Norway Rushing Work on Concrete Ships

Norway is racing with America for the honor of building the first concrete vessel to cross the Atlantic. Mr. Nick Fougner, president of the Fougner Concrete Shipbuilding Co. (Inc.), Christiania, Norway, states that he hopes to cross the Atlantic within the next two or three months on one of the larger boats which his company is building.

The shortage of wood and steel in Norway has made it necessary for shipbuilders to turn to the concrete vessel in order to offset the losses suffered by the depredations of the U boats.

The *Stier*, a 1000-ton concrete vessel recently built in the shipyards of the Fougner Concrete Shipbuilding Co., is a pioneer of the type of concrete vessel that is now under construction in Norway. It is equipped with an internal-combustion 320 hp. motor, and has four watertight transverse bulkheads of concrete, which, with a reasonable cargo, makes the ship practically unsinkable.

At present the Fougner Co. has under contract 12 additional seagoing concrete motor ships, varying in size from 200 to 3000 tons deadweight, and they have built and launched about 25 floating craft of various types, including tugs, lighters, motor ships, and dry docks.

It is expected that the Norwegian builders will adopt the new protective coating developed as the result of the research work of the engineers of the Emergency Fleet Corporation. (*Official Bulletin*, July 18, 1918, p. 9)

Over 2,000,000 Rifles Produced by U. S.

Up to and including July 27, 1918, the total number of rifles produced, inspected and accepted by the Ordnance Department was 2,000,768. This number includes 1,523,156 of United States Model 1917 and 280,000 Russian ri'es. It does not include the rifles on hand when we entered the war. The number of machine guns of all types produced, inspected and accepted since the beginning of the war up to July 27 was 96,006. The output of pistols during the same time was 414,015.

Machine-gun production continues to show a steady increase, although the output at all plants fluctuates. The number of heavy Browning machine guns inspected and accepted during the week ending July 27 was 1106, a decrease of 257 under production for the previous week. Light Brownings inspected and accepted during the past week reached a total of 2621, an increase of 557 over the previous week. Since the war began and up to and including July 27, the total number of machine guns of all types produced, inspected and accepted included 8428 heavy Brownings and 14,895 light Brownings. (*Official Bulletin*, August 7, 1918, p. 3)

General Notes

At the conference of the Engineering Division, Employment Service, Department of Labor, called by Director A. H. Krom on June 28 and held at the Engineering Club, Chicago, it was resolved to make a survey and registration of all technical persons. This register is to be compiled in conjunction with the War Industries Commission and the classification will be made by employing existing agencies represented by the various engineering and technical societies. Dr. P. L. Prentis, district superintendent, welcomed the assistance of those in attendance, who were: Dean John R. Allen, Dean Mortimer E. Cooley, W. W. DeBerard, C. E. Drayer, W. H. Finley, C. Francis Harding, A. H. Krom, Edgar S. Nethercutt, F. H. Newell, Edmund T. Perkins, J. A. Peterson, Dr. P. L. Prentis, Isham Randolph and George C. Dent.

The Government has now taken definite action designed to keep engineering students under military age in college until they complete their courses. The War Department plans to conserve this important war material through the establishment of Students' Army Training Corps in all the engineering colleges to supplement the Reserve Officers' Training Corps. Members of these organizations will be placed in the inactive service of the United States and will be classed in 5 D of the Selective Draft.

Such students will wear regulation uniforms furnished by the Government and will be required to attend training camps for a period during the summer vacations.

The draft board will not include such men in calls for induction so long as they remain in the Students' Army Training Corps.

By order of the Federal Government, the War Industries Board will supervise the filling of order of turbines of over 700 hp. This necessity grew out of a situation that developed when the Navy Department, the War Department and the Emergency Fleet Corporation were found to be competing for motive-power units, each claiming priority over the others. The twenty-one manufacturers that come under Government control have agreed not to fill orders for turbines in excess of 700 hp. for either civilian or Government purposes without a permit from the War Industries Board. It was indicated that all but a small portion of their output will be distributed between the Navy, Shipping Board and the War Department.

Detailed schedules of turbine engine requirements are being drawn up with the utmost care and will contain all necessary specifications to enable the War Industries Board to distribute the business to the best advantage among existing plants. (*The Iron Age*, vol. 102, no. 5, August 1, 1918, p. 274)

About 350 pieces of spruce are required in a single airplane. Practically all of the available spruce is in the United States and along the western coast of British Columbia. In the face of many complex problems existing in the spruce stands of the West, the Spruce Division of the Aircraft Bureau made a distinct record. In 45 days the world's largest sawmill was erected at a cost of $200,000; 1940 men operate it working in three shifts of eight hours each. A drying plant costing $350,000 was built at Vancouver Barracks and there spruce is seasoned by a kiln process worked out by the Forest Products Laboratory of the Forestry Service which effects a saving in shipping weight of 33⅓ per cent. The total spruce and fir shipped to June 15, including a large amount of each shipped to the Allies, is: spruce, 52,000,000 feet; fir, 20,800,000 feet. (*Official Bulletin*, August 7, 1918, p. 7)

The United States Fuel Administration reports a saving of coal at the rate of 350,000 tons annually in its campaign for fuel economy in steam-power plants. This saving has been initiated through the inspection of 300 of the larger plants. It is estimated that 20,000,000 tons of coal can be saved, and as fast as the work can be accomplished each of the 250,000 plants in the country will be inspected.

The Fuel Administration also announces the organization of the Industrial Furnace Section, Bureau of Conservation, to handle fuel conservation in all furnaces with the exception of those operated for the production of power, heat, and light. This includes those plants using fuel for direct heat, such as in the clay-products industries. This section is in charge of an experienced engineer who has under his immediate supervision 13 districts comprised of 31 states, covering the territory in which industrial furnaces are used. Each district has a local head who has in his organization an advisory board and a corps of inspecting engineers. A probable annual saving is estimated of 3,000,000 tons of coal.

Aeronautics

Aluminum Pistons for Aeroplane Engines. Reprint of the official report received by the editors from the controller of the Technical Department, Aircraft Production, British Ministry of Munitions, on aluminum pistons from the 230-hp. Benz engines.

Some features are of interest. The domed head of the sand-cast aluminum piston is supported and strengthened by eight webs radiating from a central boss in the piston crown. Three cast-iron rings are fitted above the gudgeon pin and one scraper ring is provided below the gudgeon pin.

The rings are concentric and machine-hammered on the inside. They are exceptionally deep in section, being 5.25 mm. deep and only 3 mm. wide vertically. The piston-ring gap measured in position in a standard 230-hp. engine cylinder was found to be exceptionally wide, namely, 1.9 mm. The compression ratio is believed to be slightly higher in the engines fitted with the aluminum pistons than in the standard 230-hp. Benz, namely, 5.021 instead of 4.9421. (*Engineering*, vol. 106, no. 2740, July 5, 1918, p. 18, 4 figs., *d*)

The Present State of the German Aviation Program, E. H. Sherbondy. Brief historical review of the German aviation program in the last three years with some data on its present state. The most interesting part is that referring to the tests to which new planes for military purposes are put. (*Aerial Age Weekly*, vol. 7, no. 20, July 29, 1918, pp. 961-965, illustrated, *g*)

Air Machinery

Testing Air Compressors, N. S. Tennant. Description of tests on a 4000-cu. ft. Belliss & Morcom (Birmingham, England) air compressor. The data are of interest in view of the scarcity of data of tests of large air compressors.

In the present instance the output of air is controlled by a valve at the compressor intake, designed to operate intermittently, completely opening and closing as required to maintain a constant air pressure in the receiver. By this method the compressor runs continuously at full load and at its highest efficiency until such time as the demand for air is less than normal, when on a slight increase in the receiver pressure the intake valve shuts completely and the compressor runs unloaded. Under this condition the first-stage air piston runs in a partial vacuum and in the second stage the air in the clearance spaces is compressed to the discharge pressure and re-expanded to the intake pressure at every stroke. The compressor therefore runs either at full load or at no load.

The compressor in question is electrically driven by a three-phase induction motor running at a constant speed of 243 r.p.m. It is of the vertical two-stage double-acting type and is directly coupled to the driving motor.

The paper describes in detail the methods of carrying out the tests. The full-load tests were carried out by coupling the compressor to a steam engine, indicator cards being taken at frequent intervals. The no-load tests were made by driving the compressor by a 50-b.hp. direct-current motor previously calibrated on a Heenan and Froude water brake and directly coupled to the compressor for tests.

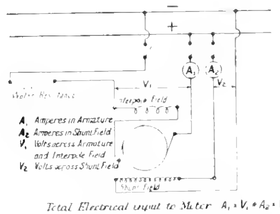

Fig. 1 Diagram of Electrical Connections for Testing Compressor at No Load by Direct-Coupled D. C. Motor

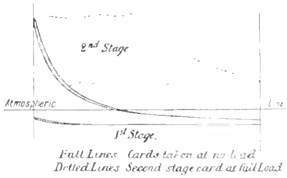

Fig. 2 Indicator Diagrams of Second-Stage Compressor Test (Full Lines: Cards Taken at No Load; Dotted Lines: Second Stage Card at Full Load)

The diagram of the electrical connections is shown in Fig. 1. The water resistance shown in the armature circuit was introduced to limit the armature current, thus protecting the motor against overloads occurring during the tests. Such protection was necessary, because if for any reason the air-inlet control valve opened during the tests, the full-load torque of the compressor would be applied to the motor.

The results of the run are shown in Fig. 3. The power at the commencement of the tests when everything was cold was, as might be expected, appreciably higher than when the normal

working temperatures were reached. The maximum power recorded at the start was 47.8 b.hp., which gradually fell with the rising temperature to the steady value of 38.2 b.hp.

Indicator diagrams shown in Fig. 2 were taken. These diagrams, among other things, show that the slip or leakage of air past the air valves is extremely small. Thus, the second-stage delivery valves have the full discharge pressure on them all the time, and any considerable air leakage would have greatly increased the area of the diagram. The temperature of the air at the compressor discharge was found to register no more than 100 deg. fahr. throughout the no-load tests. The loss due to mechanical friction alone could be deduced by subtracting the residual air i.hp. from the measured b.hp. input, which gave 38.2 — 16 = 22.2 b.hp. As a check

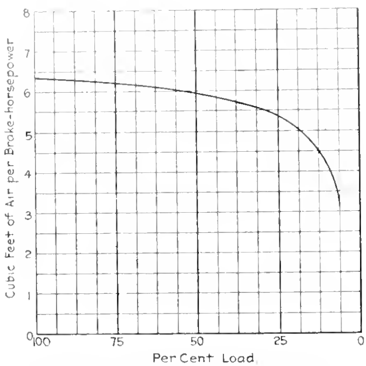

FIG. 3 EFFICIENCY OF BELLISS AIR COMPRESSOR AT VARIOUS LOADS IN CU. FT. OF AIR PER B.HP.

(Capacity, 4120 cu. ft. free air per min.; air pressure, 80 lb. per sq. in.)

on this result, the air pump was reconnected to the compressor discharge and a vacuum of about 15 in. applied. Cards taken under this condition were straight lines, no area being visible showing that the residual air hp. had been eliminated.

The input power to drive the compressor was found to be 21.6 b.hp., a result reasonably close to that deduced from the indicator diagrams. The mechanical efficiency of the compressor on the full-load test was found to be 93 per cent, which would indicate that the frictional losses increase from 3.25 per cent at no load to about 7 per cent at full load.

A further test was made to determine the loss due to piston-ring friction alone and for this purpose the first- and second-stage pistons were removed from the air cylinders. Under these conditions the power taken to drive the compressor at 243 r.p.m. was found to be 9 b.hp., this figure representing the frictional losses in the compressor bearings, main guides and metallic packing, the loss due to the piston rings alone being then 21.6 — 9 = 12.6 b.hp., or, roughly, 58 per cent of the total friction. The piston rings were examined after the test and found to be in correct adjustment, showing a good bearing surface without being unduly tight.

The no-load losses may therefore be divided as follows:

Residual air horsepower	16.6 b.hp.
Piston ring friction	12.6
Friction in bearings, guides and metallic packings	9.0
Total	32.2

Engineering Materials

BRASS WEAKNESS, James Scott, Mem.Am.Soc.M.E. A microscopical investigation of brass purporting to throw some light on the causes of its mechanical weakness.

Broadly, the constitution of brass is divided by the author into three distinct grades: red, yellow and white. In the red, copper is predominant and the stage consists entirely or nearly so of alpha crystals which retain many of the qualities of the copper component and are soft and ductile. The yellow stages consist mostly of beta crystals which are stronger but not as ductile as the preceding. The white stages consist principally of gamma crystals and are very brittle. In the white stage zinc predominates and the crystals have a silvery luster.

One can, however, obtain, as it were, overlapping stages in which alpha crystals are yellow and the beta crystals red, the results depending on the action of certain proportions of the respective metals caused to undergo special processes.

A common brass may be composed of all three types of crystals most intimately mixed up, but it is the facility with which internal changes occur that most affects the mechanical properties of the metal.

Copper and zinc begin to separate out from the molten alloy at different temperatures and owing to the vaporizing tendencies of the zinc the routine of crystallization during solidification of the mass is seriously interfered with.

The writer makes some interesting remarks on the subject of the colors of the crystals which appear to be subject to surrounding influences. For instance, yellow alpha crystals appear as the vicinity of 71 per cent of copper is approached and the alloy is rapidly cooled. When the copper content is from 64 to 58 per cent and the alloy is cooled at 470 deg. cent., alpha crystals with the yellow tinge are exuded from the red beta crystals.

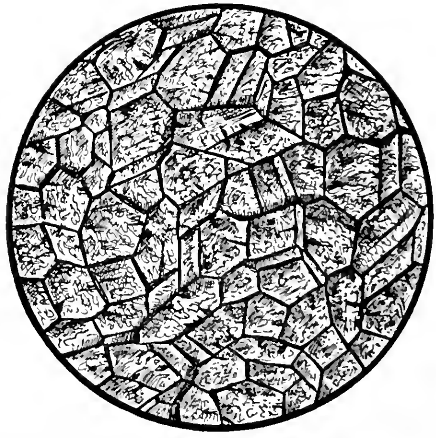

FIG. 4 CRYSTALLINE STRUCTURE OF AEROPLANE NAIL BRASS IN NORMAL STATE

A brass containing from 71 to 64 per cent of copper is, when just solidifying, made up of a mixture of alpha and beta crystals. After slow cooling, however, at 400 deg. cent. or annealing at this temperature the beta crystals become absorbed by the alpha crystals and the latter largely predominate. But further changes are possible. Beta crystals may be restored and then again vanish, especially if increase of temperature accompanies the physical action. This is why alloys con-

taining down to 60 per cent copper can only be cold-worked, while those for hot-working have to be composed of 63 to 50 per cent copper.

Commercial white brass is almost all of the gamma stage, there always being less than 45 per cent of copper present.

Rapid cooling may suppress a certain state in brass, but this is capable of prominently reasserting itself at atmospheric temperatures, the reversion being accelerated should the metal be struck or vibrated.

The writer gives illustrations taken from an etched surface (with chromic acid) of an aeroplane brass nail head. Fig. 4 shows the normal state of the metal. The grains are small and compact. Fig. 5 shows the same metal after distortion by hammering. The original grains have been forced together to form larger ones and the structure is decidedly weaker. Fig. 6 shows the same with the grains split up irregularly and crevices appear between them. This latter is due to the fact that mechanical strains and temperature variations have first caused the particles to momentarily squeeze together and after relief from the modified action to reform as much larger angular grains. The straining consequent upon such changes loosens the grains, some of which by concentration or shrinking leave crevices around their boundaries, while others gradually cleave crosswise.

This may explain the frequent dropping off of aeroplane nail heads. (*The Metal Industry,* vol. 16, no. 7, July 1918, pp. 319-320, 3 figs., *pt*)

Forge Shop

Development of Flaws in Hollow Forgings, A. S. Hesse. Discussion of mistakes sometimes made in the production of hollow forgings which will cause serious flaws to develop in the piece of steel being worked.

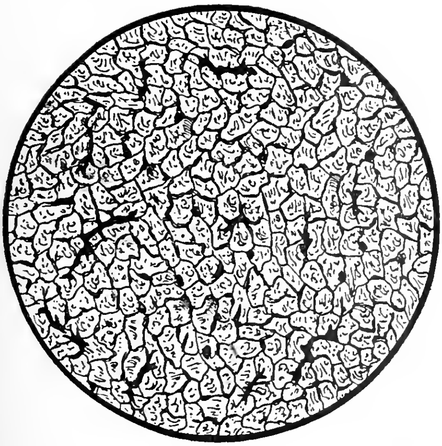

Fig. 5 Crystalline Structure of the Same Material as in Fig. 4 After Distortion by Hammering

There are three such mistakes: namely, using too small a mandrel, using flat dies in the hydraulic press or hammer, and working the metal too cold. The first of these three is by far the most serious.

The writer shows and illustrates how the use of an excessively small mandrel may develop a fissure. The worst of it is that it is possible that this fissure may not be seen at first in the interior of a long, hollow forging until its sides are crushed together. Whether the seam so formed extends deeply into the material or not, the stress which has been developed will be a vital factor in the ultimate strength of the piece.

The flaw caused by a mandrel which is too small can hardly be avoided even where the long axis of the oval hole is placed exactly vertical, for the forging is squeezed down with a tendency to form seams on both sides.

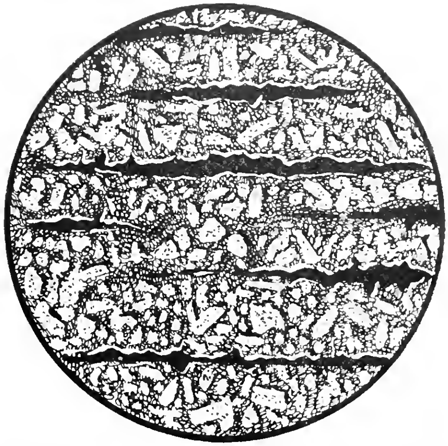

Fig. 6 Crystalline Structure of Same Material as in Fig. 4 After Being Subjected to Mechanical Stresses and Temperature Variations, Showing Cracks and Crevices

The writer also points out that seams which were formed as very minor affairs at the start will work or "travel" along and grow deeper should the smith start going over the forging a couple of times to round it up. The best practice is to draw and finish a section and stop when it no longer draws on account of the low heat and only bends from one oval axis to another. (*American Machinist,* vol. 49, no. 4, July 25, 1918, pp. 153-154, 3 figs., *p*)

Question of Quenching Oils for Forgings, Geo. W. Pressell. The writer discusses under the basis of experiments the results in quenching with different oils. He claims that the quenching speed of an oil depends on its heat-conducting properties and also on its fluidity or viscosity. Decomposition of the oil entails a reduction of the quenching speed and, in general, the more viscous an oil the slower will be its quenching speed.

The most interesting part of the paper is that illustrated by Fig. 7, showing the hardening power of distilled wool grease.

Wool grease has been known for several years and is claimed to have unusual powers of heat circulation and heat absorption. It is also claimed that it does not decompose after repeated use or show indications of further fractional distillation.

Tests were made for quenching speed at different temperatures. The test piece was made from low-carbon chrome-vanadium steel 17 in. long and $3\frac{1}{4}$ in. wide. All heating was done in lead and the test piece was heated to 1200 deg. fahr., then quickly immersed to a constant depth in 25 gal. of the quenching fluid, the immersion being such that the quenched mass was equally surrounded on all sides by the same depth of quenching fluid. A stop watch was used to measure the

time required to cool the test from 1200 to 600 deg. fahr. The following data were obtained with distilled wool-grease oil:

Temperature of quenching bath, deg. fahr.	Seconds.	Temperature of quenching bath, deg. fahr.	Seconds.
82	97	190	102
97	99	202	102
112	102	215	105
125	104	222	106
138	103	230	104
149	102	238	105
160	101	247	103
170	101	249	102

The average quenching speed was 102 sec. The total variation was 9 sec.

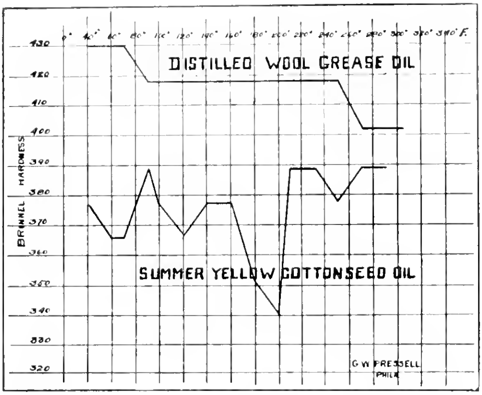

Fig. 7 Curves Showing Hardening Power of Distilled Wool Grease and Yellow Cottonseed Oil

Tests were also run on heat conductivity, oxidation and volatilization of various oils, as well as a test to determine the life of oil distilled from wool grease and the effect of constant use.

The system of quenching with its appliances, such as quenching tanks, cooling of the oil, etc., are discussed in brief. (Paper presented at the Fifth Annual Convention of the American Drop Forge Association, abstracted through the *American Drop Forger*, vol. 4, no. 7, July 1918, pp. 273-277, *ep*)

Fuel and Firing

Coal Saving by the Scientific Control of Steam-Boiler Plants, D. Brownlie. The first of a series of articles promising to be of quite unusual interest.

It is proposed to give the average figures for 250 typical steam-boiler plants covering the period from 1910 to the present time with the object of supplying accurate data on possibly conservation of fuel through the adoption of scientific methods in the boiler house.

The present article describes the method of carrying out the tests and begins the detailed analysis of the results of the 250 tests. (*Engineering*, vol. 106, no. 2741, July 12, 1918, pp. 25-27, *ep* 1. To be continued)

Fuel Conservation on the Santa Fe, Charles E. Parks. Description of the methods used in the past ten years for fuel conservation on the Santa Fe system.

In 1909 over 3½ billion lb. of coal were consumed in producing approximately 16 billion gross ton-miles; in 1917 the gross ton-miles had increased 55.9 per cent, while the pounds of coal used had only increased 17.8 per cent. The pounds of coal consumed per 1000 gross ton-miles was 227 lb. in 1909 and 171 lb. in 1917, or a decrease of 24.7 per cent.

It is recognized that this decrease in fuel consumption was due to many factors outside of the activities of the fuel department of the individual railroad system: such as the proper design and maintenance of locomotives; the use of larger power plants; construction of second tracks; reduction of grades; elimination of curves and general improvements in the line; lengthening passing tracks and greater efficiency in train handling.

The Santa Fe fuel department works along two general lines: first by educating the actual users of the fuel in its economic use, and second by an inspection and supervision of the physical factors in fuel consumption.

The education of the enginemen and the firemen has been materially assisted by a system of fuel accounting which not only discloses the conditions as they exist at the fuel stations daily, but also shows the amount of fuel consumed by each individual engine on each trip. In addition to the engine crews, much effort has been made in educating the fire builders, fire cleaners, hostlers and helpers in roundhouses. Further, the fuel question on the Santa Fe is recognized as something in which the transportation department is interested as well as the mechanical department. Dispatchers are constantly impressed with the importance of economic fuel consumption in handling trains and it is also forcibly brought to the attention of conductors, trainmen and other operating employees. The inspection department sees to it that the coal is free from slate both at the mines and at the fuel stations. The operation of coal chutes is under the supervision of the department and all coal-chute foremen and laborers are carried on the department roll. Attention is also given to the unloading of coal and the loading of engine tanks to prevent waste in yards and along the right of way.

The article describes in detail the system of accounting, and, in particular, the individual fuel records.

The writer sums up the whole situation by saying that waste in fuel like loss and damage claims cannot be reduced to zero, but the record of the Santa Fe shows that it can be materially reduced when a systematic effort is made. (*Railway Review*, vol. 63, no. 4, July 27, 1918, pp. 124-127, *p*)

Internal-Combustion Engineering

Four-Cycle Versus Two-Cycle Diesel Engines. Discussion of the relative merits of these two principles as applied to Diesel engines.

It is generally admitted that the larger the power the better is the case for the two-cycle principle; and furthermore, the Diesel engine is free from some of the most severe objections to the two-cycle principle. Thus, scavenging with Diesel engines is carried out by air alone and not by a mixture of air and gas, which eliminates the danger of ignition of the incoming gas or of the loss through the exhaust ports of part of the charge.

Franco Tosi, of Milan, Italy, have recently built two similar engines; one a two-cycle and one a four-cycle, which they have tested one against the other with a view to comprehensive comparison.

The two-cycle engine has six working cylinders in the center with a scavenging pump and a compressor at each end. The four-cycle engine has eight working cylinders with two compressors at the forward end. There are also other differences required by the respective cycles of operation.

Both engines are of the same b.hp., namely, 1300, which is the standard submarine-engine size of the makers.

Lengthy tests were carried out, 145-hour continuous non-stop runs being made and both engines developed their designed power of 1300 b.hp. at 300 r.p.m. It was found, however, that the two-cycle engine was not capable of developing higher than this figure, whereas the four-cycle engine at the same speed gave 1450 b.hp. and as a maximum power at higher revolutions developed 1585 b.hp. for a short period. As regards fuel and lubricating oil consumption, the advantage lies greatly in favor of the four-cycle engine. At full load the four-cycle figure was 0.41 lb. of fuel and lubricating oil per b.hp. hour, whereas the two-cycle consumption was 0.573 lb. per b.hp. hour.

It is of interest to note that with the two-cycle engine at 300 r.p.m. the compression was 460 lb. per sq. in., whereas at 120 r.p.m. the compression fell to 315 lb. per sq. in., at which pressure the temperature would be insufficient to support combustion of heavy fuel oil and so the engine would stop. With the four-cycle engine at 300 r.p.m. the compression pressure was 490 lb. per sq. in. and at 100 r.p.m. had fallen only to 445 lb. per sq. in.

Messrs. Franco Tosi have decided, in future, to abandon the two-cycle principle, and to confine themselves to the four-cycle for reasons substantially as stated, which may finally be recapitulated: 1. Elimination of the scavenging air pumps with their receivers, diminishing thus the size of the engine and decreasing the noise. The four-cycle engine of equal power is, approximately, the same size and weight as the two-cycle. 2. Lesser amount of heat units abstracted by the cooling water and the four-cycle engine contributing to the lower-fuel consumption with the four-cycle engine. 3. The inefficiency of scavenging with two-cycle engines, as compared with the four-cycle. 4. The possibility of using higher piston speeds with the four-cycle engine. 5. Greater flexibility of the four-cycle engine. 6. Simpler mechanical parts of the four-cycle engine. 7. The fuel pumps and valve gear of the four-cycle engine only ran at half the engine speed, making thus for easy running conditions. (*Engineering*, vol. 105, no. 2739, June 28, 1918, pp. 727-728, editorial)

"Gasteam" Plant at Ford City, Ontario. Description of the combination gas and steam plant now being erected by the Ford Motor Company of Canada, Ltd., on the Canadian side of the Detroit River at Ford City, Ontario.

On the whole the plant follows closely in design the general arrangement of the well-known Highland Park Plant in Detroit, where boiler feedwater is employed to recover waste heat from gas-engine cylinder jackets.

One of the most interesting features of the plant is in the gas-producer installation where tar separated from the gas is returned to the producer and gasified. It is stated that this method of tar disposal proved to be preferable to the old system of burning the tar under the boilers, as the heat value of the gas is increased considerably when the tar is gasified.

At present there are two Smith gas producers and a third is being installed. Each producer is built up in six sections. The rate of driving in each section can be separately controlled so as to prevent channelling and unequal blast distribution in the fuel bed.

As regards the operation of the producer plant, the following information is given: On leaving the fire the gas passes through a brick-lined hot pipe to a primary cooling tower where its temperature is reduced from about 1100 deg. fahr. to 120 deg. fahr., or to a temperature that will insure efficient operation of the tar extractors. It then passes through a low-pressure header into the exhauster, which delivers the gas under 3 lb. pressure to the tar extractors. After the tar is removed the gas enters the secondary cooling tower where the temperature is reduced to approximately that of the atmosphere before being delivered to the gas engines and to furnaces in the shop.

The fuel bed in the producers lies at an angle of 35 deg. and when the grates are shaken the fuel moves obliquely along the inclined bed. Three firemen on top of each producer watch closely for holes, channels and ridges in the fuel bed, particularly along the wall. The depth of the fuel bed averages about 5 ft. on the high side of the grade and 7 ft. along the back wall.

Exhaust steam is used to saturate the air blast to the producers. A thermostatic valve automatically controls the steam supply so as to maintain the temperature of the blast at 140 to 150 deg. fahr.

In the operation of the thermostatic valve a curious phenomenon was discovered. The valve had been adjusted to open and close slowly, gradually changing the quantity of steam being admitted to the producer. By regulating it so that it would open and close at the rate of two times per minute, admitting the steam in puffs, the proportion of carbon monoxide could be maintained at 25 per cent and the carbon dioxide cut down to 3½ per cent. The probable explanation for this is that in the first place steam coming in contact with incandescent carbon forms water gas high in carbon monoxide. As the motor-operated valve closes the decomposition zone increases rapidly in temperature, as only dry air is entering the combustion zone. When the valve opens it allows a considerable quantity of steam to enter and strike the incandescent carbon, which again forms water gas, with the result that the producer gas is made high in carbon monoxide.

Some trouble was at first experienced with tar delivery. At first the tar pipe was jacketed, but this was found to be unnecessary, for when the tar is recirculated it becomes as fluid as machine oil. A 2-in. line without steam jacketing is now used and the pumps have been replaced by a steam-pressure tank with steam at 880 lb. pressure. At first tar from the sprays tended to saturate the fuel bed, but this trouble was overcome by increasing the number of spray nozzles from three to five and thus distributing the tar more evenly over the fire. The gain in thermal efficiency by gasifying the tar averages from 8 to 9 per cent. (*Power*, vol. 48, no. 6, August 6, 1918, pp. 186-193, 13 figs., *d*)

Lubrication

The Lubrication of Michell Blocks. A mathematical discussion of the problem. In the applications which have hitherto been made of Osborne Reynolds' theory of lubrication, it has been customary to assume that the viscosity of the lubricant does not vary as it passes through the bearing. On this assumption it follows that for efficient lubrication a Michell block must be supported behind its center of figure in order to secure the necessary film of oil between the opposing surfaces; and, moreover, such a block, if centrally supported, should have no load-carrying properties whatever. By actual experiment it was found, however, that a centrally pivoted block could carry quite a high load and it was pointed out by H. T. Newbigin, in 1914, that this was due to the fact that in applying Reynolds' theory the variation of the viscosity of

the oil as it rose in temperature during its passage through the bearing was neglected, and that when this factor was taken into account the experimental facts were quite in accord with theory.

For a block infinitely wide as compared with its length, measured in the direction of motion, Osborne Reynolds gave the equation:

$$\frac{dp}{dx} = 6\lambda \frac{h - h'}{h^3} \quad \ldots\ldots\ldots\ldots\ldots [1]$$

where p denotes the pressure of the oil, x the distance of any point of the block from the origin, λ the viscosity of the lubricant, while h denotes the distance separating the opposing surfaces at any point x, and h' is the value of h at the point where the pressure is a maximum.

In integrating this equation Osborne Reynolds assumed λ to be constant, although it is known that the temperature of the oil may be increased by its passage under the block. Some time ago this subject was investigated theoretically and experimentally in the laboratories of Brown, Boveri & Co., of

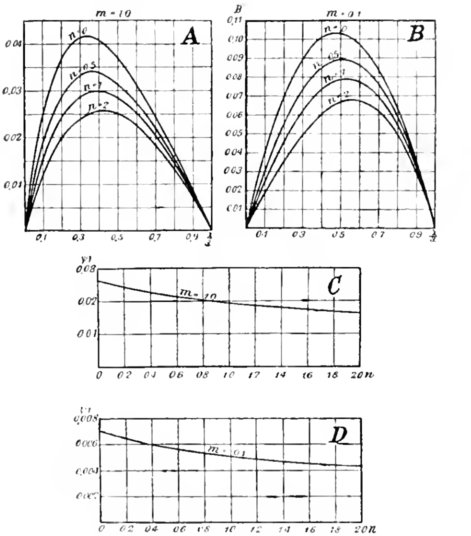

Fig. 8 Curves from Tests on Lubrication of a Michell Block

Baden, Switzerland. In this investigation the assumption was made that the viscosity λ may be expressed in the form

$$\lambda = \lambda_0\left(1 + \frac{n}{a}x\right)$$

Here λ denotes the viscosity of the oil as it *leaves* the block, while a denotes the length of the block and n is a coefficient. The viscosity of the oil as it enters the block is therefore $(1 + n)\lambda_0$.

With this substitution Equation [1] can still be easily integrated and the results for practical values of the constants m and n are given in Fig. 8, *A* and *B*, taken from the house organ of Brown, Boveri & Co. called *Revue B.B.C.* In these figures m is defined by the relation $h = h_0\left(1 + \frac{mx}{a}\right)$ where a is, as before, the length of the block taken in the direction of motion and m represents the inclination of the block to the other bearing surfaces.

It appears from Fig. 8-*A* that when $n = 0$, that is to say, when the viscosity is constant, the maximum pressure and the line of action of the resultant pressure lie distinctly behind the center of the block.

Fig. 8-*B* corresponds to a much smaller angle between the opposing bearing surfaces and in this case the change in viscosity has a much greater influence on the position of the center of pressure. This becomes nearly coincident with the center of the block when the viscosity is only 50 per cent more at the leading edge than at the trailing edge, while with $n = 2$ the center of pressure is well forward of the leading edge.

The two curves appear to indicate that to carry a given load the oil film will be thinner with a centrally pivoted block than with one which is pivoted behind the center line. This thinner film will be subject to a more severe shearing action and the development of heat should be greater than with the center of pressure behind the center of the figure.

The Swiss investigators have also determined the total load carried per unit width of an infinitely wide block when the viscosity varies according to the law already assumed above. Denoting this total load by $\frac{P}{b}$, they find that:

$$\frac{P}{b} = \frac{6\lambda_1 U a^2}{h_0^2} \cdot \varphi_1$$

where $\lambda_1 = \lambda_0(1 + n)$ denotes the viscosity of the oil at the leading edge, λ_0 being the viscosity at the trailing edge. U is velocity of motion, h_0 the least thickness of the film and a the length of the block measured in the direction of motion. The function φ_1 depends on n and m only. Its value for different values of n when $m = 1$ is given by Fig. 8-*C*, and when $m = 0.1$ is given by Fig. 8-*D*. Fig. 8-*C* shows that if the viscosity is three times as much at the leading edge as at the trailing edge the load carried is only about eight-thirteenths as much as if the viscosity were constant at its highest value. With $m = 0.1$ the relative carrying power diminishes with varying viscosity in approximately the same degree as with $m = 1$.

The original article describes tests made to determine the truth of the above conclusion and also experiments on the coefficient of friction.

In conclusion, the writer in the *Revue B.B.C.* points out that Michell's calculations show that when a block is of finite dimensions the displacement of the center of pressure from the center of figure becomes greater the narrower the block is as compared with its length in the direction of motion. The effect of side leakage is therefore to increase the eccentricity of the resultant pressure on the block, while on the other hand the rise in the temperature of the oil tends to decrease this eccentricity. (*Engineering*, vol. 105, no. 2739, June 28, 1918, pp. 714-715, 4 figs., *et*)

Machine Shop

Fusion-Welding Fallacies, S. W. Miller. Continuation of an article the first installment of which appeared in the July number of *Machinery*. The writer discusses here several of the commonly accepted but erroneous opinions about fusion welding. He points out that a weld which has not been heat-treated is not suitable for all engineering structures; that thermal changes in structures are neither negligible nor easily corrected: that coarsening of the grain reduces the ductility and resistance to shock of the metal, and these conditions cannot be entirely overcome by heat treatment although a material improvement can be made.

The structure of weld cannot be made as good as that of the original material, because the finest grain and therefore the

best physical qualities can only be obtained by using both heat treatment and some mechanical treatment like forging. As forging cannot be done in most welds it is evident that the best results cannot be secured. An electric weld in the opinion of the writer is not superior to an oxy-acetylene weld. (*Machinery*, vol. 24, no. 12, August 1918, pp. 1082-1084, 11 figs., *cp*)

Machine Tools

Milling Machine with New Type of Drive. Description of a constant-speed driven type of milling machine in which 16 changes of spindle speed and the same number of feed rates are available, all of which changes are obtained through sliding gears controlled by two ball-joint levers, the tumbler gear in the feed-change mechanism having been eliminated. The power is transmitted through a single driving pulley operating at a constant speed and all the shifting of gears is done on secondary shafts underneath. (*The Iron Age*, vol. 102, no. 4, July 25, 1918, p. 207, 1 fig., *d*)

Mechanics

Critical Loading of Struts and Structures, W. L. Cowley and H. Levy. Many interesting questions of practical importance relating to the failure of structures under compression have been brought up by a study of the problems of the strength of aeroplane framework. The present paper is an attempt to solve problems relating to the strength of such a construction as a beam under end thrusts, supported at intermediate points.

The writers believe that there are two types of failure of a structure. On the one hand, the material of a member may rupture on account of the yield stress having been exceeded during the course of the loading; while, on the other hand, the loading may be such that the geometrical configuration previously existing can no longer be maintained even approximately. It is the second type of failure which forms the chief subject of discussion in this paper. The writers start with the discussion of an elementary case such as, for example, when a prismatic homogeneous rectilinear uniform strut with simple supports at the end is loaded both laterally and longitudinally, as in Fig. 9.

AB is the strut simply supported at the ends A and B. Let w (pounds per unit length) be the intensity of lateral loading at P of coördinates x and y. Let M_1 and M_2 be externally applied bending moments at the ends. The writers consider the equilibrium of the beam taking the origin at A and AB as the axis of x.

The bending moment at P is given by

$$F.y - M_2 + (M_2 - M_1)\,(l - x)/l + H(x)$$

where $H(x)$ is the bending moment at P due to the lateral loading alone. Equating this to the resisting moment, viz., $-EI$ (curvature), and assuming the deflections small, we find that

$$-EI\frac{d^2y}{dx^2} = F.y - M_1 + (M_1 - M_2)x/l + H(x)\ldots\ldots[1]$$

where $H(x)$ does not involve M_1 and M_2.
This equation may be written

$$\frac{d^2y}{dx^2} + \lambda^2 y = M_2\lambda^2/F - x\lambda^2(M_2 - M_1)/Fl - \lambda^2 H(x)/F\,.\,.[2]$$

where $\lambda^2 = F/EI\ldots\ldots\ldots\ldots\ldots\ldots\ldots[3]$

From this the writers proceed to show that the bending moment at any point can only become infinite when

$$\sin \lambda l = 0\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots[8]$$

unless at the same time

$$M_1 \cos \lambda l - M_2 + F\{X(0)\cos \lambda l - X(l)\} \rightarrow 0\ldots.[9]$$

Equation [8] indicates that when the length of the strut is given by

$$\lambda l = \pi$$

that is, $l = \pi\sqrt{(EI/F)}\ldots\ldots\ldots\ldots[10]$

bending moments and deflections become excessively large compared with those allowable by the analysis. Equation [10] is the commonly recognized expression for "Euler's strut."

It should be particularly noted that under these conditions Equation [9] reducing to

$$M_1 - M_2 = -F\{X(0) + X(l)\}\ldots\ldots[11]$$

furnishes a relation between the externally applied bending moment which may prevent the struts failing in the Eulerian sense. It is suggested that in a structure in which M_1 and M_2 are determined by the loading and configuration of the system, it may be possible to have present a strut of Euler's length without failure resulting.

It appears then that in the simple case treated above, a

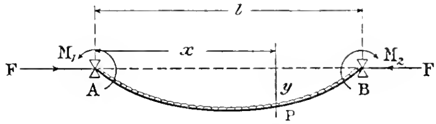

Fig. 9 Prismatic Homogeneous Rectilinear Uniform Struts With Simple Supports at the Ends Loaded Both Laterally and Longitudinally

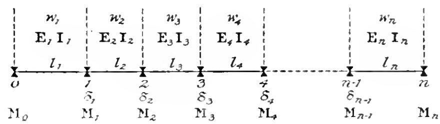

Fig. 10 Beam with $n + 1$ Supports

critical loading of the beam is essentially associated with the production at all points of bending moments and deflections excessively large in comparison with those allowable by the assumption upon which the analysis is based.

This immediately suggests that failure, in a corresponding sense, may take place in a more complicated structure and that these criticals will be furnished from the expressions determining the bending moments on the assumption of small deflections by inserting the condition that the former become infinite.

The next case discussed is that of a uniform beam under end thrusts, where the central axis is constrained to pass through $n + 1$ fixed points. For this case formulæ are derived, by means of which the loads on each bay are defined in terms of the dimensions of the bays, their flexural rigidities and the longitudinal loading in addition to the lateral loading. Thus is given an extended form for the equation of three moments, or Clapeyron's theory, when the axis of the beam is constrained to pass through given points and when both lateral and longitudinal loading exist.

Next is considered the case of $n + 1$ supports and n bays figured in such a manner that the rth bay appears to the left of the support numbered r as in Fig. 10. For this case a system

of equations is obtained from which if the bending moments at any two supports (usually zero and ∞) be known the remaining bending moments are uniquely determined, and once the bending moments at all supports have been evaluated the determination of the bending moment in each bay becomes a simple matter.

The next matter inquired into is the suggestion that the presence of a bay of Euler's critical length would not of itself involve failure of the type here considered. In common engineering practice failure is often assumed to be the case.

The writers sum up this case in the following manner: A beam supported at any given number of simple supports will not fail in general through the bending moments becoming excessive, even if some of the bays are of Euler's critical length, provided one bay, at least, is not of this length. Whether or not this will correspond with the stable loading of the structure will depend on whether or not the actual longitudinal load, if any, that would produce infinite bending moments is greater or less than Euler's load for the bays in question. It appears , therefore, that the presence of bays of Euler's length is not in itself either a necessary or sufficient criterion for instability.

On the other hand, where one of the bays is twice Euler's length, the writers find that the equation giving the relation between the bending moments contains an infinite term, and since the coefficients of these bending moments and the remaining terms are all finite, it follows that one, at least, of the bending moments must become infinite and the structure must fail. This is, however, not the lowest critical loading.

The following statement is made as to the conditions of failure of a supported system:

The criterion of failure which will be utilized in the present discussion is, as already explained, the production of infinite binding moments at the supports. Associated with this will be the assumption already known to be valid in the case of a single strut, that for values of the longitudinal force greater than the least that will produce these infinite bending moments, the geometry of the structure will not be maintained, the failure, in this sense, thus corresponding with instability. It remains, therefore, to write down the mathematical expression which must be satisfied when the bending moments are infinite and to determine the least root, regarding it as an equation in F, the longitudinal force.

The case of clamping supports is considered in detail, two cases being specially inquired into, namely, where the beam is clamped at either or at both ends, and determinational conditions corresponding with critical loading are given. On the whole, the writers believe that clamping one or both ends is equivalent to a direct addition of strength, the exact magnitude of this increased safety being dependent upon the smallest root of the determinant regarded as an equation in F, the longitudinal force. (Paper read before the Royal Society, January 2, 1918, abstracted through the *Proceedings of the Royal Society*, Series A, vol. 94, no. a662, pp. 405-422, 7 figs., *t* A)

A DOCTRINE OF MATERIAL STRESSES, R. F. Gwyther. The purpose of the paper is to provide a reasoned basis for a theory of stresses applicable in the first case to a body which satisfies the geometric conditions for acting as a rigid body (not being in a state of constraint), but which shalt be capable of extension to elastic bodies or to other approximations to material bodies without introducing the fiction of an "undisturbed" condition in whic the body is assumed to be free from stress.

The body contemplated is not supposed to be crystalline, fibrous or annealed and not to be subject to any special conditions either locally or at the surface.

The general reasoning is expressed by the writer in the following manner:

(1) The nine elements of mechanical stress obey well-known laws of resolution. By introducing the notion of infinitesimal rotations of the coördinate axes about their own positions, we can, for our present purposes, replace these relations by the three differential operators, acting upon the elements of stress, the determination of which follows from the laws of their resolution; that is, these operators are based on mechanical considerations.

(2) If we now consider any arbitrary vector (which we shall speak of conveniently as a virtual or potential displacement), we may look upon the nine first differential coefficients of its components as being replaced by the nine elements of virtual or potential strain (including among them the three rotations).

These nine virtual strains may now be affected by the same infinitesimal rotation of the axes as is employed in (1), and the three consequent differential operators acting upon the elements of strain may be deduced: in this case on geometrical grounds. It will be noticed that the forms of the two sets of operators are similar, and may easily be made identical.

(3) I shall now introduce the fundamental assumption on which the theory is based: namely, that the elements of a material stress are functions of the first differential coefficients of the components of some vector quantity; in other words, functions of some set of nine virtual strains.

(4) If we now turn to the two sets of differential operators concerning elements of stress and of virtual strain, we are able, in consequence of assumption (3), to express each element of stress in terms of the nine elements of virtual strain; or conversely, each element of strain in terms of the nine elements of stress, by means of sets of simple partial differential equations.

In obtaining these solutions constants will be regarded as uniform and isotropic, and, consequently, we shall exclude, among other things, the possibility of a crystalline structure. We shall also suppose the body not to be in a state of constraint, or otherwise that that state has been eased. I shall, further, limit the solutions to relations of a linear form. From this it will follow that the relations between the elements of stress and of virtual strain agree, in form, with the corresponding relations familiar to us in the Theory of Elasticity.

(5) Supposing the elements of virtual strain to be expressed in terms of the elements of stress, we may eliminate the former by differentiation, and obtain a set of relations involving only the elements of stress (stress relations).

(6) I shall now suppose the set of three mechanical stress equations to be introduced which correspond to the state of rest or motion of the body as a rigid body. With these equations I shall suppose the stress relations of the preceding paragraph to be combined. From this combination we may obtain stress relations, by which we may regard the elements of stress to be defined: as far as they are capable of being defined as long as the surface-traction conditions have not been considered.

(7) Up to this point I have been contemplating such cases as a cube of metal on a rough inclined plane, or a connecting rod moving in a prescribed manner, the geometrical conditions for rigidity being preserved. The stresses are not to be regarded as undefined, but as being determinate.

(8) The Theory of Elasticity is now introduced by the definition of an elastic body as a body such that the strain, hitherto considered as a virtual or potential strain, is the actual strain

experienced by the parts of the body. The stresses being definite, the strains become definite, and the displacement may be deducted.

The acceptance of the principles involved in this doctrine would have the effect of removing the subject of stresses from its accepted place in the Theory of Elasticity, and of making it an integral part of the Statics and Dynamics of a Rigid Body. Motor-Car Engineering

Utilization of Heavy Fuels. As a result of some experiments which he conducted, the author believes the concentration of effort toward the most suitable application of additional heat to vaporize the fuel, to be undesirable. In his estimation it is necessary to endeavor to atomize the fuel more thoroughly than is generally the case in modern carbureting devices. The specializing upon the provision of heat may give satisfactory results if the problem be looked upon only from one aspect, merely to secure the complete vaporization of the fuel, but where excessive heat is solely depended upon, the end in view is attained at the expense of the volumetric efficiency of the engine.

From the particulars which have been published of certain American vaporizing systems, it appears that in the United States efforts are being directed toward the application of heat to the heavier elements only of the fuel which may be passing in unvaporized form from the carburetor to the cylinder ("hot spot" devices).

If a certain temperature is necessary to vaporize the fuel in the form in which it issues from the carburetor jet, it is obvious that more complete vaporization would occur if the same heat were applied to a more thoroughly atomized fuel. Experiments which the author made led him to believe that in the case of fuels which are not excessively heavy, judged by the present standards, it is possible to obtain better results in the way of power production and economy by thoroughly atomizing the fuel, even without the provision of hot air or hot-water jackets, than by depending upon heat alone to vaporize it. A New Chassis Lubrication System. Description of a scheme by which oil in a motor car is fed to bearings by wicks. The wicks are suspended in a reservoir of oil through a conical-shaped hole. At the small diameter of the conical hole a sharp edge is provided which acts as a barb, gripping the wicks tightly and making it impossible to pull them out from the outside.

The oil is fed to the surfaces to be lubricated by means of capillary attraction and can be regulated in the following manner: The point where the sharp edge of the small diameter of the conical hole grips the wick compresses it and this compression is varied in accordance with the amount of lubricant required for a bearing surface. When there is no relative motion between the bearing and its journal there is no flow of lubricant, as it is the movement of one surface relative to another that causes the oil that has saturated the wick to be wiped off and become distributed over the bearing surface.

In Fig. 11 a brake-countershaft assembly is shown in which oil is employed for lubrication though not on the system above described. The trunnion bearings shown eliminate any chance of the brake countershaft and tube binding from frame weave when the truck is passing over irregular road surfaces. Munitions

The Stokes Gun and Shell and Their Development. Sir Wilfred Stokes. Third Gustave Canet lecture delivered

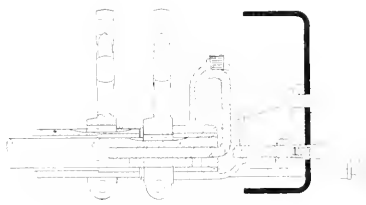

Fig. 11 Brake-Countershaft Assembly in Which Oil is Employed as a Lubricant

before the Junior Institution of Engineers on Monday, June 24, 1918, giving the history of the Stokes trench mortar. The article is of considerable interest as it explains not only the actual construction of the various parts, but also the ideas underlying their design in connection with this novel application. The paper is illustrated by halftones. (*Engineering*, vol. 105, no. 2739, June 28, 1918, pp. 719-723, 20 figs., *d*)

The 3-In. Anti-Aircraft Gun, Model 1918. The first description of this interesting apparatus. The gun is built up of nickel-steel forgings consisting of a tube, jacket and bridge ring assembled by shrinkage.

The gun weighs 1948 lb., has a total length of 129.69 in. and a length of bore of 4 calibers, equivalent to 120.04 in.

The weight of the projectile, shrapnel type, is 15.95 lb. and the muzzle velocity is 2400 ft. per sec. (*The American Machinist*, vol. 49, no. 5, August 1, 1918, pp. 185-190, 5 figs., *d*)

Physical Chemistry

The Solubility of Ammonia, M. J. Eichhorn. An extensive article reviewing in detail the previous work done on the subject.

The numerical data previously obtained have been plotted on a Cartesian diagram, Fig. 12, which illustrates the outstanding discrepancies in the values collected from various sources and permits the estimation of the magnitude of the probable errors.

From this diagram it appears that at ordinary room temperatures the agreement between the values for atmospheric pressures is fairly good, but for temperatures near the freezing or boiling point, or for pressures considerably above or below the atmospheric, the few data available are far from being in harmony.

The lines of equal pressure in the right half of the diagram

seem to converge toward a point located below the lower right-hand corner, and in order to investigate this matter further the diagram was anamorphosed and the scale for t recalculated, so as to make the line for $p = 1.0333$. The end points were taken at $t = 0$; $N = 1202.8$; and $t = 102$; $N = 0$; the scale for N was left as a regular scale. Now, calling x the distance, measured on a regular scale, from the point $t = 0$ to the point t, it follows from the proportionality of the sides in the two right-angled triangles, that

$$1202.8 \div 102 = (1202.8 - N) \div x; \text{ from which}$$

$$x = 102\,[1 - (N \div 1202.8)]$$

With the scale for t determined by the last equation, and the

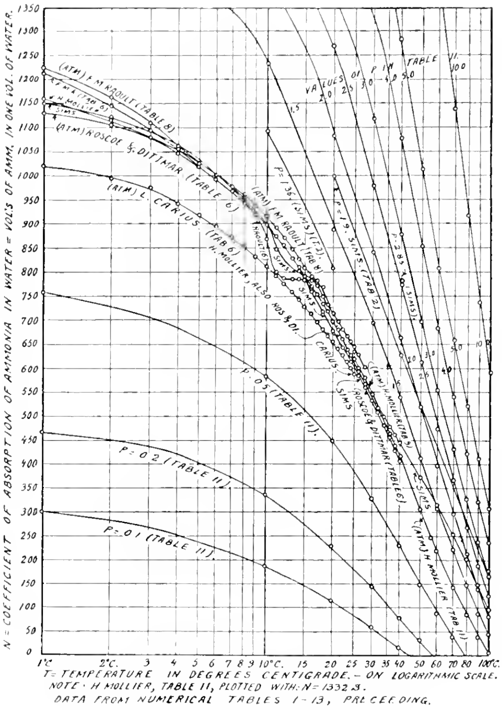

FIG. 12 DIAGRAM FOR SOLUBILITY OF AMMONIA

same regular scale for N, a new Cartesian diagram is constructed and the lines of equal pressure, plotted on such a system of coördinates, prove to be reasonably close approximation to straight lines and meet in one point, diagonally below the lower right-hand corner.

The diagram was further anamorphosed into one with three groups of intersecting parallel lines by a method which the author believes to be original with him. It is a method of perspective geometry and consists essentially in rejecting the point of radiation to infinity. If we consider the eye located in the plane of the last-mentioned diagram, and in the point in which the equal-pressure lines coincide, and further that the plane of the diagram is intersected by another plane, at right angles to the same and also at right angles to the line connecting the eye with the zero point of the diagram, and beyond the latter, then each numbered point on the coördinate axis may be considered as having a perspective image on the new plane. These image points, taken together, form two scales for N and t, and when the eye point is considered as receding to infinity, then of course all the lines, connecting each image point with the same, become parallel. When the new scales for N and t thus obtained, are taken as the coördinate axes in another Cartesian diagram, the lines of equal pressure, plotted on same, will be straight parallel lines. In this diagram the scale for N is a linear scale, the general equation for which is

$$x = (ma + n) \div (pa + q)$$

In order to convert the last-mentioned Cartesian diagram into a nomogram of aligned points, Fig. 13, the equation of the N-scale, obtained by the method outlined above, was figured out by taking four arbitrary points and forming four equations with m, n, p, q as the unknown quantities and solving for the same. The resulting formula for the N-scale is

$$x = 26\,a \div (a + 2100)$$

Again utilizing the relation $N = 1332\,S$, the equation of the S-scale becomes

$$x = 51.8\,a \div (a + 1.568)$$

in which

a = number of the point

x = distance of the point from zero

S = fraction of a pound of ammonia to one pound of water.

The writer constructed a second nomogram for solubility of ammonia in which the Mollier equation of condition is laid as a basis, with the results given in both the customary and the metric units. Power-Plant Engineering

DETERMINATION OF HEAT GIVEN OFF BY ENGINES AND POWER PIPING, Dr. E. V. Hill and W. J. Mauer. Some time ago the Engineering Department of the City of Chicago requested the Ventilation Division of the Health Department to conduct tests with the view of determining the amount of heat supplied to the engine rooms of pumping stations by the engines and power piping in the building.

In order to determine the net heat supplied by the equipment it is necessary to determine the air change in the building under average winter conditions, and one must also know the heat loss from the building due to temperature differences on the inside and outside of engine-room walls.

The article describes in detail the method of carrying out the tests. The air change in the engine room was determined by the reduction of the carbon dioxide content shown by hourly readings. In this way the air change curve shown in Fig. 14 was obtained.

As regards heat losses, the question was somewhat complicated by the fact that the materials of construction in the building varied at different elevations. Further, on account of the height of the room there was a difference in temperature of 40 deg. between the air at the floor level and the peak of the roof. Hence in computing the heat transmission through the wall the temperatures to be used must be those corresponding to that part of the wall in question. For this reason temperatures were taken at various points and the temperature curve (Fig. 15) drawn, this curve being approximately a straight line. The original article gives a detailed calculation of heat losses through the windows in one of the walls in which use is made of this temperature curve.

On the whole it was found that one complete air change required about 56½ min., and results were obtained showing the total heat losses through the floor, roof, edge of the walls and

through the air change, respectively. (*The Heating and Ventilating Magazine*, vol. 15, no. 7, July 1918, pp. 18-24, 9 figs., *e*)

Railroad Engineering

First of the U. S. Standard Locomotives. Description of the first of the standard locomotives, namely, a light Mikado type built by the Baldwin Locomotive Works for service on the Baltimore & Ohio.

There is nothing of an unusual character either in the general design or the details of construction. The boiler is of the conical wagon-top type, 78 in. in diameter over the first course, increasing to 90 in. in outside diameter at the dome course, Fig. 16. The longitudinal seam of the dome course is on the left-hand side of the center line, and the reinforcing pad on the inside of the shell under the dome is extended to form the inside welt strip of this seam. The longitudinal seams of the conical and front courses are at the right and on the top center line of the boiler, respectively. These seams are all welded at the ends.

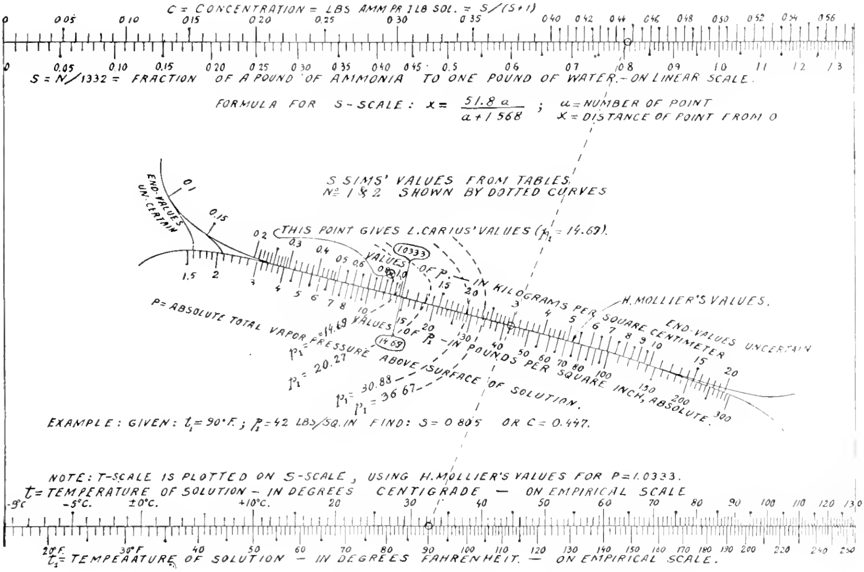

Fig. 13 Nomogram for Solubility of Ammonia

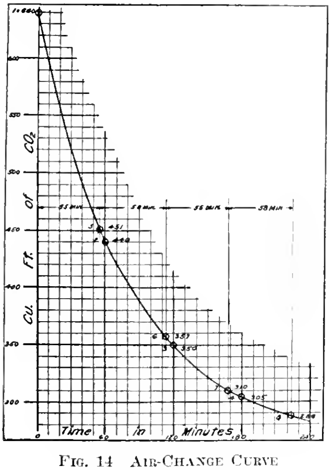

Fig. 14 Air-Change Curve

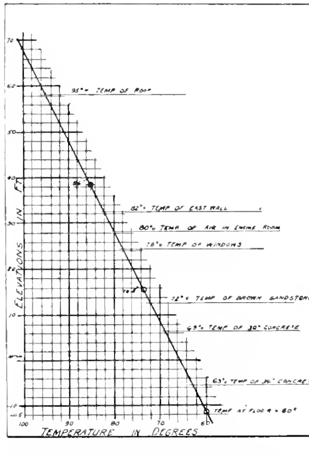

Fig. 15 Curve for Determining Temperature at Various Elevations in Engine Room

On the basis of Cole's ratios, the boiler capacity rating is practically 96 per cent of the cylinder requirements in respect to the heating surfaces, and slightly over 100 per cent in respect to the grate area. The tubes are 2¼ in. in diameter and

19 [illegible] over the tube flues, the ratio of the diameter to the length of tubes being about one to 100. The firebox includes a combustion chamber 24 in. long and is fitted with a security arch. The boiler includes a 40-unit Schmidt top header superheater with 5½ in. superheated flues, and is fired by a Duplex stoker. It is fitted with a Shoemaker fire door.

The ashpan has three center hoppers with swinging drop bottoms. The opening under the mud ring is 5½ in. wide. The grates are operated by a Franklin grate shaker. (*Railway Age*, vol. 65, no. 3, July 19, 1918, pp. 131 to 133, 5 figs., e)

Refrigeration (See Physical Chemistry)

Steam Engineering (See also Internal-Combustion Engineering)

A NEW THEORY OF THE STEAM TURBINE, Harold Medway Martin. Presentation of a new theory of the steam turbine in which the leading idea is that steam is not in thermal equilibrium where it was hitherto supposed to be.

In the investigation of the performance of steam turbines some notable discrepancies between theory and apparent practice were discovered, one of these being that under certain conditions the weight of steam discharged from a nozzle was actually greater than what was physically possible according to the then accepted theory. At first it was attributed to the moisture in the steam, but this explanation was discarded when it was found that to bring this theory into accord with experiment would involve the presence of anywhere between 10 and 20 per cent of moisture in the steam. Later on this anomaly was attributed to a fundamental error in the then accepted theory of the efflux of steam; namely, that the expansion of wet steam did not proceed under conditions of thermal equilibrium as was previously assumed.

The present theory is based on an assumption claimed to be proved by actual experience with steam turbines; namely, that not only is steam not in thermal equilibrium in the "saturated field" of the Mollier diagram, but it is never in thermal equilibrium until the condenser is attained. The relation between volume and pressure during the expansion of wet steam is accordingly never the same as if thermal equilibrium were established.

In opening a turbine it is easy to see the difference in the appearance of the blading which has been exposed only to superheated steam and that which, on the ordinary theory, has been subjected to the action of wet steam. In the region where the steam was supersaturated a film of moisture is deposited on the blading and it is this very phenomenon that for a long time interfered with the detection of undercooling in steam turbines and steam engines. In any attempt to take the temperature of the steam by means of a thermometer a film of moisture was immediately deposited on the bulb or on the exterior of the thermometer pocket if the steam were supersaturated, and the thermometer recorded the temperature of this film and not that of the surrounding vapor. Hence, for many years it has been noted that the temperature of the steam as indicated by a thermometer placed in a turbine exhaust pipe was sensibly below that corresponding to its pressure. These low readings are all the more remarkable in that experiment has shown that a thermoscope immersed in a current of a permanent gas tends to give too high a reading, owing to adiabatic compression of the fluid against the obstacle.

The writer mentions a possible objection against the idea that there is any large degree of undercooling in the turbine exhaust, viz., the fact that in experiments with nozzles discharging into open air Dr. Stodola showed that once condensation commenced it proceeded with extreme rapidity. However, he calls attention to the fact that the occurrence of condensation or even its completion does not necessarily imply the simultaneous establishment of thermal equilibrium. In fact, there is evidence in favor of the view that there is a sensible lag between the two.

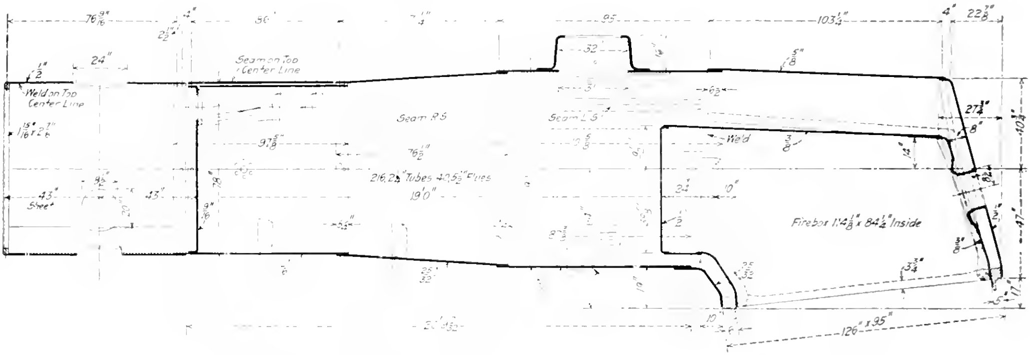

FIG. 16 BOILER OF THE RAILROAD ADMINISTRATION STANDARD LIGHT MIKADO TYPE LOCOMOTIVE

In the experiments of Stodola the droplets observed by him in his jets of undercooled steam were formed in a period of time of the order of one ten-thousandth of a second, while the time occupied by steam in flowing through the low-pressure end of a turbine is some hundred times as great. Were it not for the lag between condensation and thermal equilibrium, it is difficult to see how these droplets could be built up with such rapidity. Each molecule as it condenses liberates energy sufficient to raise its own temperature by some 500 or 600 deg. cent. and were this energy immediately and wholly transformed into heat, it is difficult to see how the temperature of the surface could be kept low enough to permit of the building up by further condensation of droplets observed by Dr. Stodola.

The author also brings forward the following interesting reasoning to prove that the instantaneous conversion into heat of the energy liberated on condensation is unlikely. He claims that the forces responsible for the attraction between the molecules of the same substance to which the phenomenon

of liquefaction is due, are essentially of the same nature as the forces holding together a chemical compound, i.e., electrical. There are thus good grounds for believing that the energy liberated on the condensation of a vapor is at the outset represented by electrical disturbances and is only somewhat gradually converted into the form of heat. In support of this view the writer cites the paper of Wilson in the *Philosophical Transactions* for 1897, where the latter states that if the expansion of dust-free vapor was just sufficient to produce condensation the number of droplets formed was of the order of 10^8 per cu. cm., but that this number increased very rapidly if the range of expansion was increased. This affords direct proof that the additional condensation took on new nuclei and the temperature of the vapor must accordingly have been far below the equilibrium value during the whole range of expansion. The time taken for the expansion in Wilson's experiments was estimated at something over 1/50 of a second and was thus of the same order as the total time taken for steam to pass completely through a modern steam turbine, the inference being that the steam as finally discharged from such a turbine is used in a greatly undercooled and supersaturated condition.

The author in his present paper attempts to show that if his interpretation of Wilson's results be accepted (*i. e.*, that the expansion continues with the vapor temperature far below that which would be indicated by any thermometer immersed in it) both superheat and vacuum corrections can be rationalized, while a contrary view involves wide discrepancies between theory and practice.

For this purpose the author gives a somewhat modified Callendar steam table (Fig. 17).

Until Professor Callendar took up the matter, the formulæ used to represent the properties of steam were wholly empirical and were very commonly mutually inconsistent. Thus the values deduced for the specific heat of superheated steam from the experiments of Knoblauch and Jakob and adopted as the basis of certain well-known tables are quite inconsistent with the specific volumes of the steam also given in the same tables, the discrepancy being as much as 20 per cent. Callendar's formulæ have, on the other hand, been deduced from considerations of the physical nature of steam and the known laws of thermodynamics. Their form has been fixed by theoretical considerations, and the coefficients only determined by experiment. All the formulæ are mutually consistent with each other and agree with the only reliable experimental data so far available. In preparing the chart Callendar's formula for the isentropic expansion of steam was employed, viz.:

$$p^{-3/13}\,T = \text{constant}$$

where p denotes the absolute pressure of the steam and T the absolute temperature. Starting with high-pressure steam at a given entropy, the absolute temperature attained on expansion to a lower pressure was then determined by Callendar's equation for the total heat of steam, which in pound-centrigrade units is:

$$H = 0.47719\ T + 464 - \frac{144}{1400}\cdot p\left(\frac{13}{3}\times 0.4213\left(\frac{373.1}{T}\right)^{10/3} - 0.01602\right)$$

At least seven points were calculated for each curve represented on the diagram. The computations were made with five-figure logarithms and checked by examining the differences. This test led to the detection of a few small isolated errors, which were duly corrected. The calculation was made to five figures and the plot to four figures.

One innovation which is thought to be of importance is that the abscissæ values are not values of the total heat H but of $2.2436\ (H - 464)$. As a result, specific volumes can be obtained from the diagram with great accuracy.

It is merely necessary to divide the abscissa reading by the pressure, and to add the constant 0.0123. For example, the abscissa reading corresponding to 90 lb. and 240 deg. cent. is 536.65. Hence the specific volume is:

$$(536.65/90) + 0.0123 = 5.962 + 0.012 = 5.974$$

The value given in Callendar's tables is 5.9741.

The adiabatic heat drop is measured in the same way as with the ordinary Mollier diagram. The Wilson line shown in the diagram represents the limit to which steam originally dry or superheated can expand without condensation occurring. The method used in deriving it will be set forth in a later issue, to which also will be deferred a description of the two diagrams of reheat factors.

Full lines on the diagram refer to superheated or supersaturated steam. Dotted lines and heavy figures refer to wet steam in a state of thermal equilibrium, a state which is never attained when wet steam expands inside a turbine or an engine cylinder.

Pressures are absolute, and temperatures in centigrade degrees. The entropy is constant along horizontal lines, and the total heat is constant along vertical lines. The numbers affixed to these verticals are, however, not values of H but values of $2.2436\ (H - 464)$.

Heat Drop. To find the isentropic heat drop, mark on the diagram the initial state point of the steam, and from this point draw a horizontal to the final pressure line. The length of this line measured on the scale provided is equal to the heat drop. There are two scales, one of which gives the heat drop in B.t.u. and the other in pound-centigrade units.

Specific Volumes. To find the specific volume of superheated steam, note the value of the abscissa corresponding to this state point. Divide this value by the absolute pressure of the steam and add 0.0123. To find the specific volume of wet steam in thermal equilibrium multiply the volume at saturation by the dryness fraction, which is represented on the chart by the dotted curves.

The Wilson Line. Save for the deposit of a thin film of moisture on adjacent surfaces, no condensation occurs when the saturation line is crossed during the expansion of steam (J. Aitken, 1880). The steam merely becomes supersaturated and continues in this condition until by further expansion the Wilson line is reached. Up to this limit the law of expansion and the relation between volume, temperature and pressure is exactly the same as for superheated steam. The Wilson line on the diagram has been plotted from the equation: $\log_{10} p - \log_{10} p_s = 3:76\ \sigma/T$, where p denotes the pressure of the steam and T its actual temperature; σ is the surface tension of water at this temperature, while p_s denotes the saturation pressure at T deg. absolute. The end portions of this curve have been extrapolated.

Reheat Factor. In multistage turbines the effective thermodynamic head is not the isentropic heat drop u, but is equal to u, multiplied by the reheat factor, R, which varies with the range of expansion, and with the hydraulic efficiency of the turbine. The less the efficiency the greater is the reheat factor. The useful work done in a multistage turbine having a hydraulic efficiency η_h is equal to $\eta_h Ru$.

To find the specific volume of steam after expansion from p_1 to p_2 in a multistage turbine of hydraulic efficiency η_h, determine the heat drop u, using the full-line curves of the

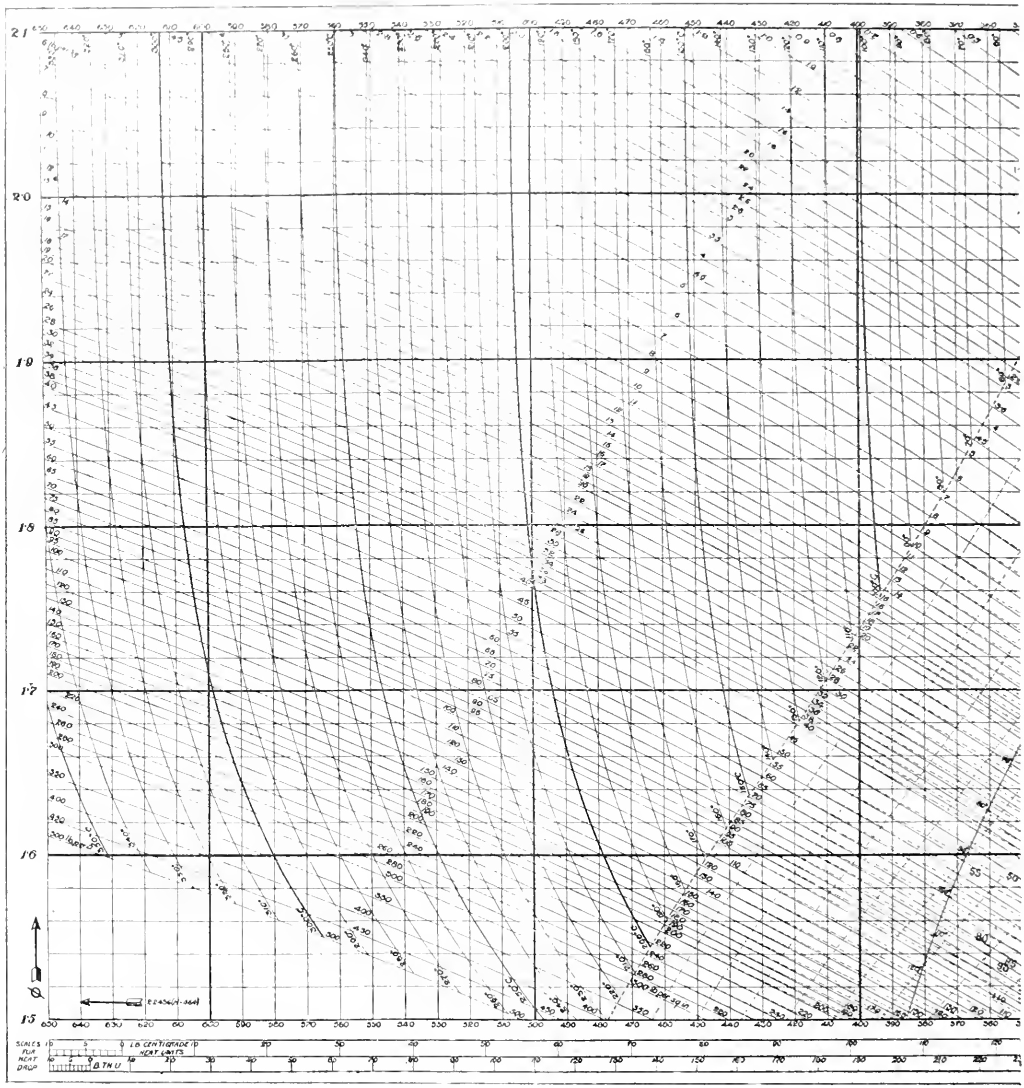

FIG. 17 HAROLD MEDWAY MARTIN'S STEAM CHART

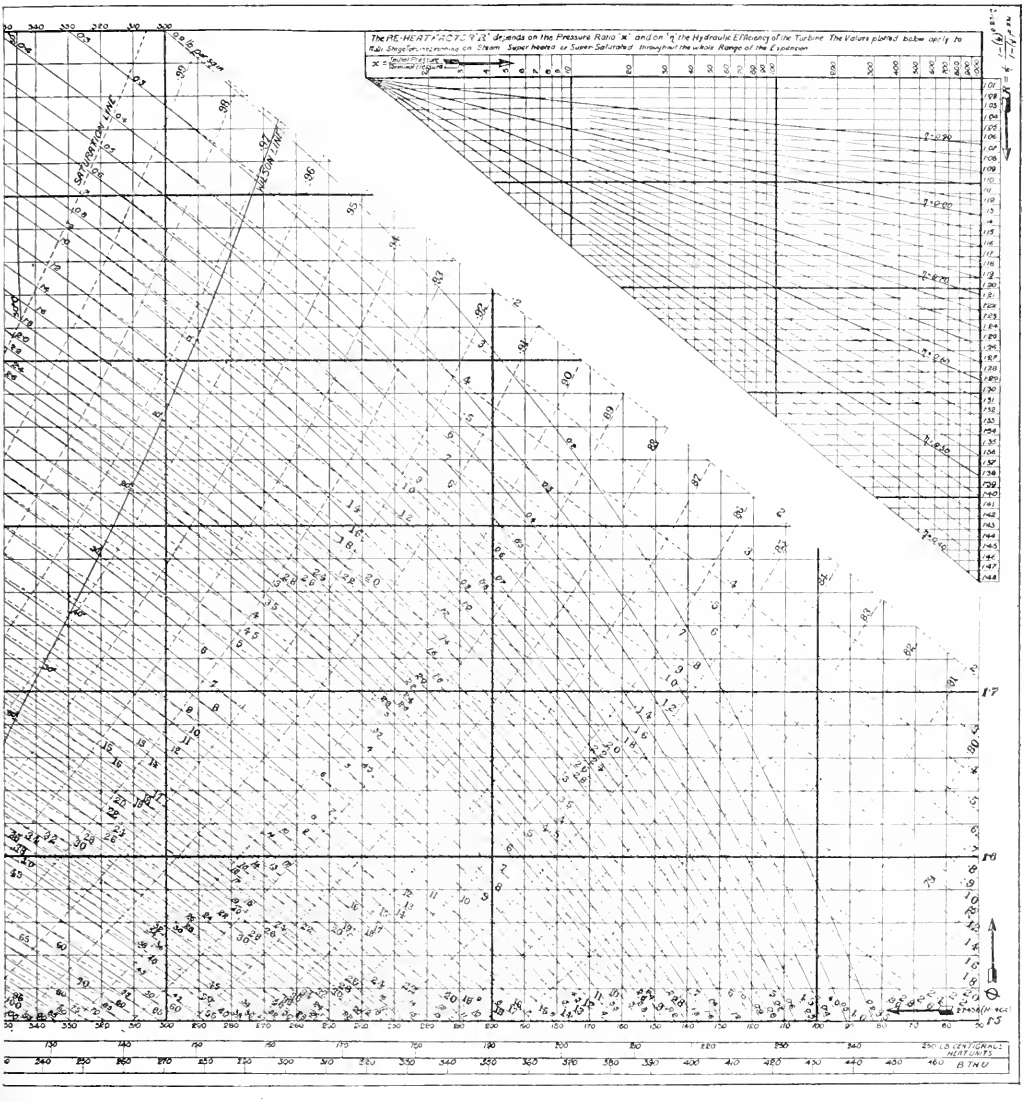
chart; next take out the reheat factor corresponding to η and to $x = p_1/p_2$. Set off horizontally from the initial-state point a distance equal to Ru^1 as measured on the heat-drop scale. From the point thus found, raise a perpendicular to cut the (full-line) curve corresponding to p_2. This intersection represents the state point of the steam after its expansion, accurately if it lies to the left of the Wilson line and roughly in the contrary case. The volume V^1 corresponding to this state point is given by Equation [2].

If the expansion be stopped at the Wilson line approximate thermal equilibrium is rapidly attained and the final state point of the steam can be found by drawing a vertical from the Wilson state point to cut the dotted line for steam at the same pressure. If the expansion be continued past the Wilson line fresh condensation occurs, but on new nuclei. The temperature during this further expansion remains therefore far below the equilibrium value and the specific volume of the steam and the work done by it are much below the values corresponding to the expansion of wet steam in thermal equilibrium.

From the superheat correction it appears that the specific volume V_w during this stage of the expansion is given approximately by the relation $V_w = 0.8V^1 - 0.2V_s$, where V^1 represents the volume calculated as above and V_s the corresponding volume and the expansion beyond the Wilson line been effected in thermal equilibrium. The value of V_s for



BASED ON CALLENDAR'S TABLES AND FORMULÆ

different hydraulic efficiencies can be found by using reheat factors taken from the dotted lines in the annexed factors.

Since the steam in expanding beyond the Wilson line is in a "dynamic" condition, it is probable that these curves of equivalent reheat factors should be bands rather than lines.

1 kilowatt-hour = 1895.5 ft-lb. centigrade units (F. P. C.)
= 3411.9 B.t.u.

1 horsepower hour = 1414.3 ft-lb. centigrade units
= 2545.6 B.t.u.

Theoretical velocity of efflux = $300.2 \sqrt{u}$ (F. P. C.)
= $223.8 \sqrt{u}$ (B.t.u.)

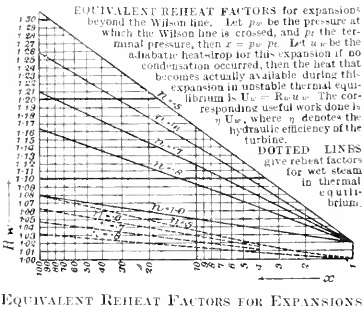

FIG. 18 EQUIVALENT REHEAT FACTORS FOR EXPANSIONS BEYOND THE WILSON LINE

Testing

Testing of Aluminum Sheets, Robert J. Anderson. In a previous article (The Journal, June 1918, p. 506) an account was given of Erichsen tests made on annealed 18-gage aluminum sheets and it was shown how the effects would become apparent earlier on cold-rolled aluminum sheets with increasing percentages of reduction. In the present article the writer discusses the use of exceedingly short time exposures at various temperatures.

It is claimed that more prolonged exposure results in over annealing, which latter produces a weakened condition of the metal and makes it unfit for drawing.

In order to demonstrate roughly how much time is required for annealing, a number of samples of cold-rolled 14-gage aluminum sheets reduced 72 per cent were exposed for two hours at 400 deg. cent. Forty blanks so annealed were drawn

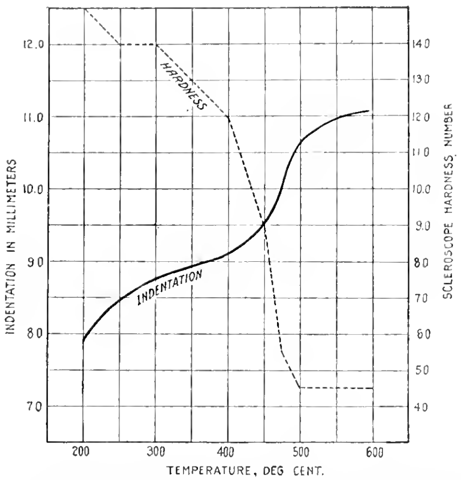

Fig. 19 Temperature-Indentation and Temperature-Hardness Curves for 14-gage Aluminum Sheets Exposed for 3 Min.

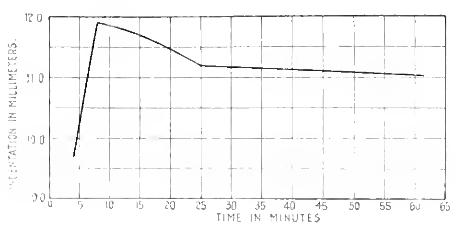

Fig. 20 Time-Indentation Curve for 14-gage Aluminum Sheets at 450 Deg. Cent.

in the draw press and all of them successfully withstood the draw.

Then some annealing experiments were performed with the view to softening the 14-gage cold rolled sheets by means of relatively short exposures at various temperatures. These annealing experiments were performed in a laboratory electric furnace of the resistance type and the temperatures given are accurate within ± 10 deg. cent. The time of exposure was 3 min. Fig. 19 gives the temperature-indentation and temperature-hardness curves for these tests and shows that the scleroscopic hardness falls off rapidly with increasing temperature and the indentation increases gradually to a maximum attained at the exposure at the highest temperature employed.

The preliminary short-time annealing experiments showed that 14-gage cold-rolled aluminum sheets could be softened at 4.5 Shore scleroscope hardness numbers by 3-min. exposures at temperatures of 500 deg. cent. and above. In the next series of tests 80 cold-rolled blanks with accompanying smaller samples for test purposes were annealed at constant temperature and variable time, as shown in Fig. 20. It was found that softening, so far as required by practice, can be effected for cold-rolled 14-gage aluminum sheets by an exposure of as little as 8 min. at 450 deg. cent.

The writer called attention to the fact that the deepest indentation value secured by the annealing tests was for sample 13, which had been exposed for 8 min. With longer exposures at the same temperatures the indentations are less deep, a fact which accords very well with the time-indentation curve of Fig. 20. (*The Iron Age*, vol. 102, no. 3, July 18, 1918, pp. 148-149, 2 figs., *e*)

Varia

The Rising Cost of Machine Building, Ludwig W. Schmidt. The writer discusses the rising cost of the elements entering into machine construction, such as labor, material and what he summarizes under the name of factory costs. A chart is given showing the variation in the margin of profit, cost of materials and cost of labor during the year 1917, which reveals a reduction in the margin of profit of noticeable magnitude.

The writer comes to the conclusion that doubt exists whether under present conditions a machine manufacturer acts wisely to cut his profit margin too narrow, and it is questionable whether even 30 per cent of the factory sales price can be called a safe margin. (*American Machinist*, vol. 49, no. 5, August 1, 1918, pp. 209-211, 1 fig., *g*)

On the Critical Absorption and Characteristic Emission X-Ray Frequencies, W. Duane and Kang-Fuh Hu. Results of an experimental measurement of the critical absorption wave-length (λ_a) and the wave-length ($\lambda\,\gamma$) of the γ line in the emission spectrum by means of a Coolidge X-ray tube with a rhodium target, the current through it coming from a high-potential storage battery. From a paper presented before the American Physical Society. (*Physical Review*, vol. 11, no. 6, June 1918, pp. 489-491)

The Relation Between the General X-Radiation and the Atomic Number of the Target, W. Duane and T. Shimizu. Investigation of the general X-radiation from the four elements iron (26), cobalt (27), nickel (28) and copper (29), to decide whether or not its intensity increases with the atomic number of the elements. Abstract of a paper presented before the American Physical Society. (*Physical Review*, vol. 11, no. 6, June 1918, pp. 491-492)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Fuel Conservation in the Petroleum Industry

To the Editor:

In few industrial fields is there a greater lack of engineering talent, coupled with a more favorable opportunity for engineers, than exists in the petroleum industry.

The drilling and pumping methods in the production of petroleum are substantially the same as they were forty years ago, and in the refineries the vast majority of distilling apparatus is identical in type with that of the earliest development, and, most significant of all, nearly all patents on distilling processes and apparatus have been granted to other than technical men.

Necessity, the mother of invention, has developed for both the driller and the refiner equipment that performs, in a measure, satisfactorily, even if inefficiently; therefore the efforts to increase efficiency have received no impetus except through the stimulating effect of large profits, and such efforts have been in the direction of increasing the production in the field and the yield in the refinery, rather than in attempting to secure increased revenue through operating refinements.

The subject of heat transfer receives little attention, the fuel used being considered merely a means to an end, yet the success of the numerous "cracking" processes hinges largely on this very question.

In the Rittman process, tubes with excessive wall thicknesses are employed to enable the use of the desired internal pressures at the temperatures necessary for "cracking," and flame temperatures, under forced draft, are allowed to impinge on a relatively small portion of the heating area.

In the Burton and other cracking processes, horizontally inclined tubes are subject to temperatures causing inevitable sagging and, only too often, rupture.

In the ordinary fire still, the desired temperatures are attained at a fuel and still-bottom-maintenance cost out of all proportion to the results obtained, and the derived vapors are condensed and the residuum cooled, at an additional expense of energy for pumping water.

The production of steam accounts for the use of nearly 50 per cent of the total fuel used in refineries, yet in the selection, installation and operation of boilers and auxiliaries little attention is paid to economy or efficiency. Feedwater temperatures in excess of 140 deg. fahr. are the exception, even with exhaust steam wasting to the atmosphere; flue-gas temperatures above 1000 deg. are common, and below 750 deg. very rare.

About fifty per cent of the steam generated is for use in the sills, the rest being used for pumping, etc. As the duty for steam in the stills is merely that of a medium for heat transfer, the exhaust from the pumps, engines, etc., is practically as valuable as live steam, but this fact is in many refineries unknown or ignored.

By the use of steam-driven electric generating equipment operating at 20 to 30 lb. back pressure (serving simply as a reducing valve), and the superheating of the exhaust steam for use in the stills, it is safe to say that 35 to 40 per cent of the present boiler fuel can be saved, and that the investment will pay for itself in twelve months in the average refinery.

In the Mid-Continent field the type of boiler commonly used is the portable locomotive-firebox boiler. Being simply a means to an end, no consideration is given it other than its portability, cost and steaming capacity, the latter requirement being according to the actual drilling need; when pulling tools and cleaning, the boiler is only half large enough, the firebox area being too small for high ratings. At these periods much time is wasted "waiting for steam."

In an article which I recently contributed to the *Doherty News* (April, 1918), it was stated that a series of tests run on both natural-gas and crude-oil fuels under 35-hp. locomotive-firebox boilers showed the average drilling boiler used 90,000 cu. ft. of gas a day or 16 bbl. of crude oil. These tests, with

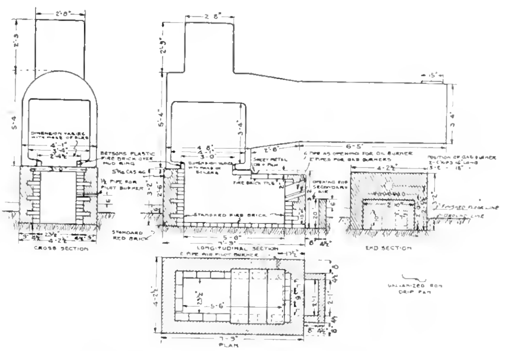

Fig. 1 Brick Sub-Furnace Used with Locomotive-Firebox Boiler

others, coupled with various experiments, have led to the development of methods and equipment which today are effecting savings in fuel consumption amounting roughly to 25 per cent.

The most notable development is that of the brick subfurnace shown in Fig. 1, which not only effects the savings shown in Table 1, but also allows double rating of the boiler when necessary.

The boiler covering consists of No. 28 gage $\frac{3}{8}$-in. "hy-rib" fitted around the boiler and securely wired on. To this is applied $\frac{3}{8}$ in. of 85 per cent magnesia, which is then coated with $\frac{1}{8}$ in. of waterproof dressing such as the combination of asbestos, gilsonite, asphaltum, etc. This covering costs about 30 cents per sq. ft., and is not only weatherproof, but will with reasonable care stand moving many times.

The portable boiler-cleaning outfit consists of a gasoline-engine-driven air compressor mounted on a suitable truck with a boiler-tube "air-hammer" scale remover, and with two experienced operators will effectually clean a boiler of all scale adhering to the tubes in two to three hours.

The price of crude oil is fixed by the pipe-line companies and is based on the average known specific gravity of oil pro-

TABLE 1 SAVINGS POSSIBLE IN OIL-FIELD BOILER OPERATION

Nature of Improvement	Installation cost per boiler	Saving per boiler per year of 365 days	
		Gas fuel	Oil fuel
Boiler Covering:			
Inside boilers	$50	$192	$480
Outside boilers	50	470	1175
Sub-Furnaces complete with Gas and Oil Burners:			
Steaming-plant boilers	60	900	2550
Drilling boilers	60	1150	3000
Feedwater Heater and Piping:			
For 4 boilers	175	275	780
For 8 boilers	125	275	780
Boiler-Cleaning Equipment with Air Compressor:			
Steaming-plant boilers	25	400	750
Drilling boilers	25	275	600

duced. Weathering and dehydration methods are responsible for the loss of 3 to 11 per cent of the total production (actual test data), yet the pipe-line companies place no restrictions upon the producer tending to discourage practices responsible for these wastes. As a matter of fact, they encourage the waste by refusing to run oil containing greater than a given percentage of water, knowing as they must that the removal of this water is almost invariably attended with considerable losses of the more volatile, and therefore more valuable, hydrocarbons.

Many of the larger producers control their own pipe lines and refineries. One of these used in the past twelve months for fuel in the fields over 300,000 bbl. of crude oil worth, at the market price, over $600,000. Forty per cent of this was entirely too valuable for use as fuel. A $100,000 topping plant would have saved this, and the investment would have paid out in a year at the outside.

I am speaking only of the operations I have witnessed in the Mid-Continent fields, but because of the investment involved they are doubtless typical.

A careful review of the professional cards appearing in the periodicals devoted to the oil industry shows that the mechanical engineering profession is very inadequately represented as compared with the geologists, mining engineers and chemists.

The U. S. Bureau of Mines is probably doing more constructive work in the petroleum industry than any other body, but there is an immense amount of work of the most valuable character awaiting the engineer in this field.

W. G. Williams.

Bartlesville, Okla.

Crippled Employees Are Able to Make Good

To the Editor:

Contrary to the general rule, our plant was in favor of older men, and had for a number of years hired the man of mature years in preference to the youth, other things being equal. We had found them steadier and to require less supervision: three-fourths of our work was manufacturing of an exact nature where these qualities counted more than semi-frequent bursts of speed. Located in a manufacturing center where piece work was general except in machine shops, it was hard to get and retain all the able-bodied men we needed, so almost unconsciously we formed the habit of arranging working operations to accommodate the infirmities of the men who generally find it difficult to obtain employment and who appreciate efforts made to enable them to earn a living, apply themselves, work steadily, and stick.

A few instances will show how we got along, and may suggest ideas for greater development in the same field. A visitor, a superintendent from a distant machine shop, was going through the plant one day, and remarked, "Where did you get all the cripples?" A year later, when the draft had cut deep into his ranks and the inducements of profiteers still deeper, he doubtless would have been glad to obtain the services of many of those cripples who had become valued employees by that time.

Several men who applied were ruptured and could not do lifting and were put to work on milling machines and punch presses. At this light labor they were perfectly safe and content. One man had lost all but the stump of a foot in a railroad accident and had worked in factory after factory, always, however, having to quit because he could not bear his weight all day on the injured foot; but on a power press he could work in comfort, and he turned out a large amount of work. This same man had picked up considerable knowledge in the operation of automatic machinery in various factories, and when a vacancy occurred he was put on a battery of screw machines; in a month's time he could set any of the automatics in the shop, and did so well that he kept five going and still found time to sit and rest the lame foot all it needed.

Another of these piece workers—a middle-aged man of known integrity and no little manual skill—had been in the shop but a short time when he asked to be allowed to bid on the "spring job"—a job of "setting" small leaf springs to a gage, an operation that kept two and three busy all the time and that could not be done accurately enough by machine. He argued that he could do the work at home, could save the hour night and morning that he spent on the way, and could work an hour or two at night. At first we didn't altogether like the idea, but after he had tried out a number and quoted us a price that would double his wages and lower our cost nearly a half, we gave in, and he has relieved us of a really troublesome job.

A telegrapher, a hunchback, who had tired of being shunted to lonely stations because of his appearance, applied for work. We had plenty of small assembling and to this his nimble fingers were fitted by long training; the work was as physically easy as his own trade and paid as much—but what was to the point, he was settled and lived at home. One of our younger men, a good lathe hand but always restless, stole a ride on a freight train on a Saturday night and came back three months later minus a foot and with a desire to settle down if we could "give him a job at something," which we did by rigging up a seat and transferring him to one of the small lathes, where he has become a genuine standby. A lad with a withered hand and a desire to work made good on a sensitive drill which was fitted up with a foot feeding attachment.

Other physical defects such as poor eyesight, susceptibility to heat and cold and dust, etc., etc., were encountered, and, if found genuine, an effort was made to supply the possessor with work that he could do in comfort. One deaf and dumb person and one who had an impediment that practically deprived him of speech were carefully instructed and in time became very speedy, reliable workmen.

The instruction of crippled men is one of the things we will undoubtedly be called upon to do in the not distant future, and the foregoing examples may serve to show what can be accomplished with a little patience and exercise of thought.

Donald A. Hampson.

Middletown, N. Y.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THESE monthly letters which the Secretary has had the privilege of writing to the membership have endeavored to bring out the decided change of thought on the part of engineers as to their obligations on the one hand and the objects and aims of professional societies on the other. Our Society has felt that we were peculiarly sensitive to these thoughts and ambitions of members, particularly those who live at a distance from headquarters, and through its Sections movement and through visits of its officers has tried to keep in touch with them. The American Society of Civil Engineers, similarly recognizing the necessity for "stock taking," has called for a conference at its annual meeting in January to consider whether or not the aims and objects of that society should be restated. As this is such an excellent suggestion, our Sections Committee has actively taken up the matter of a similar conference for the purpose of carrying out its undeveloped plans, and the President has requested Mr. L. C. Marburg of the Committee to secure preliminary suggestions.

All those interested in making the Society useful in every sense, not only to the engineer himself in the advancement of his work, but to the municipality and state in which he lives and to the nation as a whole, are invited to correspond with Mr. Marburg, in care of the Society, and at a conference to be called the latter part of October in Indianapolis and again during the Annual Meeting all suggestions will be most gratefully received. Here, therefore, is an opportunity not only for suggestions of a specific character pertaining to the proper and higher aim of the Society in its work, but for any other suggestions which a member has for the improvement of any phase of that work. The conscientious devotion of the officers of the Society can best be rewarded by the interested participation of every member in a truly democratic manner in the government and guidance of the Society in all of its activities.

Technical Men and the War

The Society very early appreciated the necessity of conserving the technically trained men, including the students in the technical schools. Officers of the Society felt this so deeply that they encouraged the authorities in Washington that it would be consistent with democracy to assign trained men according to the service for which they are best fitted, and, although considerable damage had been done before action was taken, were finally successful in staying the waste of irreplaceable material, essential not only in the firing line and in the military preparations back of the line for officers, but in the industries where many times the number of men are required as are in the actual military establishment.

Consequently this Society is to be congratulated upon its success in calling the attention of the Nation to this, and securing action on what it considered was a prime requisite. The recognition of the Administration of this necessity is now complete and it has developed an important department, namely, that of education and special training, with Dr. Maclaurin at the head of all college training and Mr. C. R. Dooley at the head of special training. The indications are that all of the educational institutions of the United States in which there are over 100 pupils will come under the direction of the War Department.

It must be recognized that the problems of the draft have been complex in the extreme, and it is the duty of every individual to credit those responsible with the same devotion to ideals as oneself.

Training of Women

Our nominee for President, Dean Mortimer E. Cooley, similarly emphasized the necessity of training women for technical pursuits at a meeting of our Detroit Section with the Detroit Engineering Society, this spring. The departments of health and several of the leading educational institutions have also emphasized the opportunities for women, but in chemistry especially, as well as in public health, there is a wonderful field for women. It really becomes a patriotic duty for parents to make sacrifices to give their daughters a technical education.

In the Service

In a brochure entitled In the Service which the members will shortly receive will be stated the degree to which the engineers, as a profession, have taken up active work in the war. The medical profession, all of whom are registered and for that reason are capable of more definite analysis, is reputed to have about 24,000 men in the service, or about 25 per cent. It is no reflection upon our medical friends to state that the engineering profession, both relatively and absolutely, has a much greater percentage.

Permanent Camp for Engineers

All engineers will naturally follow with interest the development of Camp Humphreys, at Belvoir, Virginia, about twenty miles south of Washington and just below the town of Accotink. The Camp embraces the large Fairfax tract adjacent to Mount Vernon and to Gunston Hall, the former plantation home of George Mason, the author of the Bill of Rights. Camp Humphreys has been designated by the War Department as a permanent engineers' camp of the United States and by the first of August it was expected to have about 17,000 men there; later this number will be increased to about 30,000. Officers of the Camp have called at the Society's rooms, and there may later be a proposal to the members of the engineering societies to participate in some form of headquarters for the officers of this permanent engineering camp. In the act of Congress creating the camp and its equipment, no provision for such a building is made, so this building, essential to the welfare of the Camp from a human point of view, will have to be provided through the interest and generosity of the members of the engineering profession.

Calvin W. Rice,
Secretary.

PROGRESS OF THE SOCIETY'S TECHNICAL COMMITTEES

ONE of the fundamental objects of the Society, as outlined in the Constitution is to undertake specific investigation in the field of research through the appointment of committees for this purpose. Below are given a few brief notes on the work which has been done by some of our committees during the past year.

A word of appreciation is due all the members of these committees because their work is a labor which they have undertaken for the honor and advancement of the engineering profession, and it often means to them a considerable loss of time which might be devoted to more personal aims, in addition to a financial outlay to cover traveling expenses.

Joint Conference Committee on American Engineering Standards. Due to war conditions, standardization has been brought to the front line of attention, but the final arrangements of the Joint Committee representing the most prominent engineering societies have not yet been completed. Major Barba, one of the representatives of this Society, having accepted a commission in the United States Army, Mr. Henry H. Vaughan, Vice-President of the Dominion Bridge Co., Ltd., Montreal, Canada, and President, this year, of the Canadian Institute of Engineers (formerly the Canadian Society of Civil Engineers), has accepted appointment as the third representative of the Society on this Joint Committee. The other two representatives of the Society on this Committee are Mr. Henry Hess and Mr. Wm. F. Kiesel, Jr.

By means of this Joint Committee it is expected that the activities in standardization of all engineering societies will be coördinated so as to proceed with coöperated effort for progress in the engineering profession. It is also expected that it will provide a means of coöperating with the various bureaus of the Government through its Bureau of Standards.

This Committee, it is expected, will also be the advisory body in the conduct of international standardization activities. This branch of the work, during the war, has shown a need of special attention and will be one of the activities of the Committee when they start work in the near future.

Government Commission to Standardize Screw Threads. In the May JOURNAL announcement was made that a bill was before the Congress to standardize screw threads. This bill is now a law, and it provides that this Society and the Society of Automotive Engineers are to participate in the work. Never before has the United States Government undertaken national standardization to the degree that is specified by this bill.

The Commission will consist of two representatives from The American Society of Mechanical Engineers, two from the Society of Automotive Engineers, one from the Army and one from the Navy, and a representative from the Bureau of Standards. Secretary Redfield has already invited the Society to advise him of its nominations for membership on the Commission, and the matter is now before the Council and announcement will soon be made.

It is expected that the Commission will begin its activities very shortly and that its work will be completed within the time allowed by the bill, which is six months.

Committee on Screw Threads and Threaded Parts. In order to secure coördinated effort in standardization of all parts having screw threads, it has been decided that an inclusive committee should be formed of the several committees of the Society who consider the various branches of screw-thread standardization. Efforts in this direction have been successful and the following members have accepted appointments: E. M. Herr, *Chairman*; E. H. Ehrman, *Vice-Chairman*; Stanley G. Flagg, James Hartness, A. M. Houser, Frank O. Wells.

In general, the duties of this Committee will be advisory, and it will assign work to sub-committees who in turn will formulate details. The members of this Committee will be *ex officio* members of all of the existing committees considering screw-thread standards, and such existing committees automatically become sub-committees of the Screw Threads and Threaded Parts Committee. One of the functions of this Committee will also be to follow the activities of other societies and governments in the work of screw-thread standardization and avoid duplication, and an effort will be made to bring together all interests and obtain results generally acceptable.

Joint Committee for Standardization of Machine Screw Nuts. In this work the Society is coöperating with the American Society of Automotive Engineers. This Joint Committee has prepared a tentative specification which is acceptable to the majority of machine-screw nut manufacturers. On account of the absence of the chairman, who was called by the Government for duty in Europe and was away for a period of two months in the spring, the work of the Committee has been delayed, but they are now proceeding and hope in the near future to present a report.

Committee on Pipe Flanges and Fittings. The American Society of Mechanical Engineers in appointing a committee to consider the standardization of pipe flanges and fittings, recognized the need of an industry affecting in a vital manner almost every other branch of industry in the United States.

In 1914 the Committee on the Standardization of Flanges made a report[1] on flanges from 1 in. to 100 in. in diameter for 125 lb. per sq. in. working pressure, and for flanges and fittings from 1 in. to 48 in. in diameter for a working pressure of 250 lb. per sq. in. The value of this report was immediately recognized and led to a request that the subject be further investigated, with the result that at the Spring Meeting at Worcester Report No. 3 of this Committee was presented. This report, which is in addition to the 1914 Standard, covers standard flanges for pipe from 12 in. to 54 in. in diameter with a working pressure of 50 lb. per sq. in. and flanges and fittings for $\frac{1}{2}$ in. up to 12 in. in diameter for a hydraulic working pressure of 800 lb. per sq. in. and, within the same limiting sizes, for 1200 lb. per sq. in.

The Committee further investigated and has recommended standards for hydraulic pressure of 3,000 lb. per sq. in. for flanges and fittings varying in sizes for pipe from $\frac{1}{2}$ in. in diameter up to 12 in. in diameter. This report will be published in an early issue of THE JOURNAL, as well as in pamphlet form.[2]

Committee on Limits and Tolerances in Screw Thread Fits. In the August issue of THE JOURNAL a valuable progress report of this Committee was published which it is believed has been greatly appreciated by the engineering profession. This Committee is still energetically pursuing its deliberations and is now working on formulæ for tolerances for refined, medium and rough work, and will doubtless in the near future have a still more valuable report to make.

Gage Committee. Gages are one of the things which vitally affect production, as without them the manufactured goods would not conform within the prescribed limits and the final production would fall behind the requirements. This is the condition which confronted the Ordnance, Quartermaster and

[1] Paper No. 1430, Trans.Am.Soc.M.E., vol. 36, pp. 29-57.

[2] For previous reports on flange standardization, see Papers Nos. 481, 504 and 826.

Signal Corps Departments of the United States Army, and the Engineering Division of the United States Navy, and led to the formation of a committee. It was formerly the custom—and to our regret it is still continued to a certain extent—to have various authorities for the certification of gages. This Committee recommended that there be but one place to certify gages and that these master gages be located in one or more of the important industrial centers. This recommendation has been quite generally accepted and the U. S. Bureau of Standards has been agreed upon by the several bureaus as such a place. Its practice is to certify to master gages. As announced in a previous issue of The Journal, this plan was accepted by several of the bureaus of the United States Government and has already been of great benefit in assisting in the production of munitions and all other engineering requirements for the auxiliary branches of the Army and Navy services. Our Committee, in general, has been of an advisory character and the members have traveled at their own expense to Washington and to a number of munition- and ordnance-producing centers of the United States.

War Industries Readjustment Committee. This Committee, as the name indicates, is another of those committees produced by the war and since its creation, in June this year, has been in correspondence with manufacturers and organizations in a position to render technical service of various kinds. It has brought together engineers and manufacturers and furnished names of concerns able to render technical services or to manufacture articles as sub-contractors. It has notified the regional representatives, and in many cases the War Industries Board, of the offers of services and plants. It has also directed these offers of services and plants to the War Industries Board in the various regions. The Committee is doing everything possible to effectively assist the War Industries Board.

Tin Conservation (Bearing Metals Committee). Our Bearing Metals Committee, with the approval of the President, have increased the scope of their work so as to include the consideration of Conservation of Tin, and to coöperate with the Tin Section of the War Industries Board, Washington. It is not generally known that one of the most serious shortages at this time is that of tin. In the transportation of food to our troops in Europe, tin coating of the container where in contact with the food is absolutely necessary, and the war has produced such a tremendous shortage of this metal that tin conservation is perhaps just as important as fuel, wheat and sugar conservation. Tin has been used extensively in connection with bearing-metal alloys and when the question of its conservation was brought to the attention of our Committee on Bearing Metals, they immediately accepted the work of making a careful study of the matter. Bearing metals may be made with a much reduced percentage of tin, but in the case of food containers it cannot be reduced without endangering the quality of the food.

Our Committee is now carefully considering this problem of finding substitutes for tin and the Society awaits with interest the result of their deliberations. Mr. T. G. Cranwell, Assistant to Chief in Charge of Tin, War Industries Board, Washington, D. C., and president of the Consolidated Can Co., is directly handling this work and a letter has been received from him recommending that all our members and other engineers and people who have the interests of the United States and its Allies at heart use tin with extreme care and if possible do without it, so that the necessary requirements of the Government may be met.

Power Test Code. The necessity of there being a standard code for the measurement of all power and a standard method by which such measurements will be taken has long been a recognized necessity. Our Committee was formed with the object of satisfying that requirement and it is expected to offer a progress report in the very near future. The members of the Society will await with interest news of their report.

Refrigeration Committee. This Committee has been in existence for some time and is coöperating with other interested societies.

Boiler Code Committee. The Boiler Code Committee has during the early half of the year been active in pursuing its research and investigations in connection with the work of revising the Boiler Code which was begun early in 1917. At the same time, the Committee has continued the regular monthly meetings at which interpretations have been formulated for all cases presented to it for consideration, a total, up to the present time, of 199 cases having been brought before the Committee for formal action. At the present time, the revision work on the Code can be said to be practically completed, with the expectation that the new Edition of 1918 will be published in September. Also the new locomotive-boiler section of the Code has now been placed in definite form by the Locomotive Sub-Committee, and will receive the consideration of the Committee early in the fall. The Committee is also actively at work on the proposed boiler-inspection rules.

Committee on Steel Roller Chains. This is a Joint Committee with the Society of Automotive Engineers.

Proposed Committee for the Standardization of Shafting. This proposed Committee is an outgrowth of our Committee on War Readjustment and is in process of formation. Several engineers have advised us that steel shafting manufactured only in sixteenth sizes, and with the odd sizes eliminated, would save a considerable amount of material each year.

Committee on Small Hose Couplings. This is a new Committee which is being formed and which has been in contemplation for several years. It has been found that manufacturers of small hose couplings have different standards of threads, which produce difficulties where a user has purchased couplings from different manufacturers.

Further, it has been freely stated by engineers that the small hose couplings which are used for fire and water purposes should be totally different from those which are used for gasoline and other inflammable oils. The Committee will take up the consideration of couplings, having in mind the above points for standardization of hose couplings of about $\frac{1}{2}$ in. up to about $1\frac{3}{4}$ in.

Research Committee. The Research Committee has prepared a comprehensive program and is seeking coöperation with other national bodies. Research work is perhaps at this time one of the most important activities in engineering, because the war has produced shortages of various kinds of material, some of which it has been found necessary to do without and find substitutes and others of which have had their consumption curtailed. The Council has been urged to grant an increased appropriation for this work.

Committee on Machine Shop Practice. This Committee reports that at the request of the Ordnance Department it has undertaken work on the heavy-machine-tool problem and that the Department has accepted and is carrying out many of its suggestions. For instance, an order for forty-seven 102-in. gun boring lathes is being placed with the firm that developed the reinforced-concrete machine tool, and a very large number of 87-in. lathes have been contracted to the Southwark Foundry & Machine Co., who are planning in building them to make use of all the available heavy-machine-tool capacity of the eastern district. The work is still in progress.

Big Meeting at Indianapolis

The Council of the Society will hold its October meeting in Indianapolis, and the Committee on Local Sections has decided to take advantage of this and to call a meeting of the mid-western Sections to be held October 25 to 26. Cincinnati, St. Louis, Chicago, Milwaukee, Detroit, Birmingham and Indianapolis will be the chief Sections represented officially, although the invitation to the meeting will be sent to every member of the Society in the mid-western territory, and to members of local sections of other national societies, and to members of local societies.

It is expected that the Indiana Engineering Society and the Indianapolis-Lafayette Section of the American Institute of Electrical Engineers will join in with the arrangements.

A tentative program has been prepared, which calls for a two-day meeting to be held on Friday and Saturday, enabling members to leave home on Thursday night, and to stay over at Indianapolis until Sunday night if they desire. On the first day the program contemplates the Council meeting as the first event, followed by a meeting of the Committee on Local Sections, and a conference of delegates from local committees.

An informal lunch will be held at midday, and in the afternoon there will be a symposium on the mid-western fuel situation, and it is hoped to secure Mr. David Moffat Myers, the Advisory Engineer of the United States Fuel Administration as the chief speaker, and to supplement the program with addresses from the state fuel engineers of the Middle West, and from notable speakers upon the fuel question.

In the evening of the first day an informal dinner is contemplated, and an address by President Main, and by prominent local speakers.

On the Saturday the meeting will begin with a symposium on war education, including several phases of this timely subject, with addresses by Dr. C. R. Mann, Chairman of the Committee on Education and Special Training of the War Department, if he can attend, and by Dean Cooley, President-Elect of the Society, and by a number of prominent educators in the Middle West.

It is hoped that the luncheon on the second day will be held at one of the war plants of Indianapolis, and that in the afternoon visits to points of interest will be arranged, including a visit to Fort Benjamin Harrison, which is the headquarters of the Army engineers of the state of Indiana.

The arrangements are tentative, but full particulars will be published in the next issue of THE JOURNAL.

This meeting was intended to be the first of a series of joint Local Section meetings which the Committee on Local Sections hopes to hold as a desirable means of strengthening the Local Section organization and of reciprocally benefiting local members who do not often get to general meetings.

It is easily seen that such a joint meeting as the one to be held at Indianapolis may assume the proportions of a general meeting and may secure for members all the advantages of the regular convention.

War Activities in Chicago

As announced in the August issue of THE JOURNAL (page 712) the Technical Societies of Chicago have organized for war work and for placing at the disposal of the Government and other various agencies, the combined strength and resources of the engineers of that city. The organization is called the War Committee, Technical Societies of Chicago, and coöperates with the United States Employment Service.

The headquarters of the Committee is in the office of the Western Society of Engineers, 1735 Monadnock Block, Chicago.

A general meeting of the members of the Committee was held on Thursday, August 1. It was addressed by Mr. S. J. Duncan Clark, war analyst of the Chicago *Evening Post*, on the subject Recent Developments on the War Front. The address was a popular one, summarizing war conditions as given in the daily press but going more into detail in regard to the progress of the present drive and counter-attacks.

Following the address, Mr. W. F. Abbott made a brief statement of the purpose of the War Committee which is a union organization composed of two representatives from each local society and local section to coöperate in assisting the Government. The meeting was the first of the combined Committee and the attendance was about 600.

So far the activities of the Committee have been directed to sending out employment bulletins and calling attention of engineers to opportunities in the uniformed and civilian services of the Government. Further activities will be entered upon as requests from the Government departments, which have been notified of the readiness of the Committee to serve, come in.

Committee on Development of the A. S. M. E.

Initial steps have been taken for the appointment of a Committee on Development, which was suggested in the recent letter of Louis C. Marburg of the Section's Committee, reprinted in these columns (see page 694 of the August JOURNAL). The following letter, which is self-explanatory, has been sent to all Chairmen of Local Sections:

The attached letter to the Chairman of the Local Sections Committee, Mr. D. Robert Yarnall, was discussed at a recent meeting of the Local Sections Committee which was attended by the President and Secretary of the Society.

It was the feeling of all that a committee of our Society composed mainly of representatives from all the Sections as outlined in the resolutions of the A. S. C. E. might prove of great benefit.

Many have had for years the ambition for the Society to enlarge its scope of activity to include fields allied to engineering. They have also hoped for a restatement of ideals expressing a broader conception of the engineer's duty to the community and of the position of the expert in public life. No finished program of organization can be offered, but a crystallization of ideas is needed and it is hoped that a plan of liberal coöperation between all engineering organizations may result therefrom.

The writer was instructed by President Main to communicate with all Sections and to request that each Section suggest a representative to serve on a Committee of our Society similar in form and scope to that of the A. S. C. E. Will you, therefore, please take up this matter with your Section and make an early recommendation. It is advisable that each Section be represented by a member particularly interested in this undertaking as it is expected to have far-reaching effects upon the development of our Society. In addition to one representative from each Section the President will appoint a number of members at large and if you have any names to suggest they will be appreciated.

It is proposed that an early meeting in the fall will be called at some central point to discuss the work, and while not yet authorized to guarantee the payment of mileage to delegates, the writer feels confident that sufficient funds will be available for this purpose.

Hoping to hear from you at an early date, I am,

Very truly yours,

L. C. MARBURG.

In this connection it will be of interest to learn that the American Institute of Mining Engineers has also decided to appoint a similar committee. Three of the four Founder Societies have now taken action in this matter. It is to be hoped that other societies of national character and also local societies will provide for similar discussions, as only in this manner can the best results of this important movement be secured.

Captain May Forfeited Life in Testing Oils

The notice of the death of Capt. O. J. May of Chicago, Mem.Am.Soc.M.E., an officer of the Equipment Division of the Signal Corps, which appeared on p. 573 of The Journal for July 1918, is supplemented by the following news item, which states that in consequence of the severe strain to which he was subjected while conducting a 65-hour test of a new oil for lubricating air engines, his death is held officially to be in the line of duty.

The new oil is the result of a problem worked out with great care by officers of the Signal Corps in connection with the development of the Liberty engine. At first it was believed that castor oil must be used, or at least a blend of castor oil and some mineral oil. There seems to have been no definite determination among the aircraft organizations of the Allies as to what kind of oil should be used.

The character of the lubricating oil of the air engine is of the greatest importance, as the efficiency of the engine underlies the work of the airman, and his life often depends on its quality.

It was figured out that 5,000,000 gallons of castor oil at $3 a gallon would be required for our air service, and that quantity was not in existence. The Signal Corps then went to work on a blended mineral oil to cost 75 cents a gallon.

Captain May was set to the task of testing this oil and others on running engines. In 25 days he made 37 tests on as many engines, where five tests a week was regarded as all that any one could do. Every oil was analyzed, weighed and measured before and after the run of each engine.

Captain May was exhausted when he had completed these tests. He then set to work to make an altitude test in an air-tight building with the air in it partly exhausted and kept in that state to simulate the atmosphere at high altitudes. The Captain ran several of these tests and made one of 65 hours' duration. He stood at watch without leaving the work all that time and duly recorded his data.

The strain on Captain May's vitality was too great, and when a few days later he went on an inspection trip he caught cold in a heavy storm. He died at Takoma Park, Md., near Washington, on May 22. His work has provided the Army and Navy aviation services with a lubricating oil of the best quality at a cost one-fourth of what was estimated, and it is calculated he saved the Government fully $11,000,000. One feature of the tests of this oil is the fact that half of the quantity used may be cleaned and used over again. (*New York Times,* August 14, 1918, p. 18)

A.S.M.E. Member Cited for Bravery

Captain Horace L. Smith, Jr., Mem.Am.Soc.M.E., has been cited for bravery in action, along with his entire company. Captain Smith is in command of Co. D, First Engineers, and distinguished himself in battle at Cantigny which the Americans captured and held against superior enemy forces. Captain Smith's company lost 45 men and two officers, killed during the action.

The First Engineers is a part of the First Division, Regular Army, commanded by Major General Bullard. The citation of bravery read as follows:

"Although handicapped at the beginning of the action by the loss of two officers killed and one wounded, nevertheless, it carried out its mission in a highly efficient and satisfactory manner; in addition to its duties as an engineer company, it acted as an infantry reinforcement, and during the three days suffered severely in killed and wounded."

Captain Smith was recommended for the citation for bravery in battle by the non-commissioned officers of his command, who declared that they were proud to serve under him.

Lieutenant-Colonel Parsons Now in Command of the Eleventh Engineers

Lieut-Col. Wm. Barclay Parsons has recently been placed in command of the Eleventh Regiment of Engineers, now in France for over a year. Previous to entering the war Colonel Parsons had held the rank of brigadier general and chief of engineers with the New York National Guard. He was chief engineer of the Rapid Transit Commission of New York from 1894 to 1905; a member of the Isthmian Canal Commission, 1904; advisory engineer of the Royal Commission on London Traffic, 1904; member of the Board of Consulting Engineers, Panama Canal, 1905. He has been a trustee of Columbia University since 1897, having been graduated in 1879, and is the holder of several degrees. He is a member of the American Society of Civil Engineers, the Institution of Civil Engineers, Great Britain, Société des Ingénieurs Civils de France, and has written several books and papers on engineering subjects.

In May 1917 Mr. Parsons received a commision as major and on the 14th of the same month sailed for France on a special mission for the Government to look over the railroads of that country.

Navy Factory's Year Record in Building Flying Boats

It is a pleasure to publish the following information relative to the accomplishments of one of the members of the Society:

On July 27, the anniversary of the date on which the building of the naval aircraft factory at Philadelphia was authorized, Rear Admiral Taylor, Chief of the Bureau of Construction and Repair, which built and operates the plant, reported to Secretary Daniels the satisfactory record made in its erection and operation, under the direction of its manager, Naval Constructor F. G. Coburn, Mem.Am.Soc.M.E. In recognition of this, the Secretary addressed a letter to Naval Constructor Coburn, as follows:

"The department desires to express its appreciation of your ability shown in organizing the naval aircraft factory and bringing it, as its manager, to its present state of efficiency. One year ago the construction of the naval aircraft factory was authorized by the department, and you were detailed as its manager. This factory has been built in accordance with plans prepared by you, and the records show that forms for the first flying boat were laid October 12, while the building was not completed until November 28. The first flying boat was given its successful trial flights on March 27, 1918, and since that date a steadily increasing rate of production has been observed. It is noted that the first order for 50 large flying boats has been completed and the greater part are now flying over British waters.

"It is believed that the creation in the space of one year of one of the largest aircraft factories in the country stands as a conspicuously successful example of the Navy's preparation for war."

The contract for the aircraft factory was awarded August 6, 1917, and work was begun on the same day. The original factory had a floor space of 160,000 sq. ft. An extension, which will give an added space of 55,400 sq. ft., was begun on February 26, 1918, and is now practically completed. (*Official Bulletin,* July 27, 1918, p. 5)

AMONG THE LOCAL SECTIONS

THE four years' work of the Committee on Local Sections, first as a special committee of the Society and now recently as a standing committee of administration and one of the six fundamental committees of our organization, demonstrates the value of Local Sections as an agency for furthering the several phases of the Society's work and for reaching the individual member and rendering him effective service.

However, there has been one limiting factor—the number of the Sections which have been established. In certain centers, such as Boston, Chicago and St. Louis, Local Sections of our members have been operating for some years, and members residing in these centers have secured all the advantages which come from the Local Sections organization, whereas members in other large centers where Sections have not yet been established, such as Pittsburgh and Cleveland, have not secured these advantages. In no two local centers has there been similarity of conditions, so that the matter of establishing a Local Section has been a problem unto itself in each place, and organization of local members has only come about when all concerned have been convinced of the advantages and when the local members themselves have decided upon utilizing their initiative in requesting organization.

This latter is the determining factor in the progress of the local sections movement in all societies and precludes any undue stimulation of the movement on the part of the governing bodies or any committees at headquarters of the national societies. Therefore, if the progress of organization into local groups has been slow in some desirable territories, it has been on account of the fact that the local members have for some reason or other deemed it wise to defer organization.

Now, however, comes a turning point in the history of the Local Sections and a new factor is introduced into the equation which requires local members to review their local conditions, especially in relation to the existing local societies and to determine upon a manner of organization. The Committee on Local Sections becomes one of the six main committees of the Society; the Local Sections organization therefore becomes constitutionally one of the supporting pillars of the Society. It is no longer a question of whether or not it is desirable for the Society to encourage Local Sections; it becomes imperative that the Society have Local Sections to continue to function.

This condition of things has not been brought about suddenly by constitutional amendment produced autocratically, but is merely the outcome of a number of tendencies extending over as many years as the Local Sections organization has been in existence; and, furthermore, these tendencies have not all been proposed by the Local Sections themselves—they have been originated by the central committee of the Society which has long since recognized the coming of the new order of things.

For five years decentralization in government has been under discussion in the councils of our organization, with such success that the latest proposed amendment to the Constitution means a marked step in this direction. It will be but a short while before such decentralization is completely accomplished and the power of government placed in the hands of the entire membership forever.

If the constitutional amendment securing this decentralized government goes into effect next spring, and its execution should be placed in the hands of the Local Sections, the elements in the Local Sections organization heretofore not at all similar by virtue of the unique set of conditions in each Section center will need coördination. And, as already mentioned, some of the centers where Sections do not exist, but where the local membership is strong, must be brought into committee relations and the whole Local Sections organization must be well rounded out so that all disparities are removed and the new machinery of government can be started up smoothly.

Incidentally, for some time there has been discussion regarding the desirability of completely coördinating all organized groups of engineers of whatever kind for the purpose of securing for engineers the voice in the community to which they are entitled. A rounding out of the local sections organization of the national societies such as we are about to accomplish in our own Society will go a long way toward rendering such a unification of engineering society activities effective.

The Committee on Local Sections foresees a large amount of work in bringing its organization to a condition of inclusion of all localities, but this can be very much simplified if the full coöperation of the local center is secured in each case. A certain amount of uniformity is necessary in the organization of Sections, but the difference of local conditions must of course be realized. The following thoughts regarding Local Sections and local societies might be advanced at this time:

The basis of social relations is the community, in which the engineer is one of the elements. The fundamental organization of engineers in the community is the local engineering society which includes in its membership all engineers of whatever training or experience, or in whatever field of work. Through this organized local society the engineers have their voice in the affairs of the community. The local society may be large enough to render it desirable to sectionalize its activities into civil, mining, mechanical, electrical or other engineering. However that may be, the local society still remains the unit and so long as the engineer continues to reside in the community he secures his voice in its engineering affairs through the medium of his local society. That is all he requires and that secures for him his recognized standing. Therefore, the local society must be regarded as paramount in engineering organizations.

The limit of usefulness of the local society to the individual member is reached, however, when he removes from the community and establishes himself in another territory. He must make entirely new connections and must bide his time for his standing in a new community to be recognized. There is also another limit of usefulness of the local society in its relation to the engineer at large and to the public: the local society specializes in local conditions and confines its interest to such conditions. Its meetings are usually limited in attendance and its publications have only a small circulation, and, except in a few special cases, its influence does not extend very far beyond its center of operations.

Here is where the utility of the national society comes in. It secures for its members a national and sometimes international connection, so that the limitation of community residence is entirely removed. Its meetings and publications are national and international in scope, so that its influence through these media is practically universal.

The connection between the local and national societies is established in the following manner: The activities of the national society are supported entirely by individual members, who are, in turn, usually members of local societies; and so, while the fields of operations of local societies and national societies are entirely separate and distinct, the agents perform-

ing these operations are one and the same. The two kinds of organizations therefore become inseparable and interdependent.

It is not necessary to justify further the existence of both organizations and the above comparison has been made merely to introduce the idea by which our own Local Sections organization and the local societies may be brought up to the point of active coöperation and complete coördination.

In practically every center in which we have a Local Section there is a local society, and it is the business of our section to preach the gospel that that society is the authority in the community.

In centers where we have no Local Sections there is usually, likewise, a local society and, bearing in mind that in all such centers we need organization and government, our local members should take the initiative and open up negotiations with the local society with a view to determining how our members may organize and work for the government of the national society without detracting from the autonomy of the local society.

Behind the whole organization movement of which, of course, our Society is but a small part, there is the great incentive that there remains an army of engineers in this country who have not yet responded to any calls for organization to secure for the engineer the recognition in public life which he merits. The engineering profession is lacking in missionaries—the men who will emerge from the natural conservatism which is inherent to their professional training and who will blaze the way into the halls of community government in which the engineer has so far been conspicuous by his absence.

SECTIONS REPORTS AND PROGRESS FOR THE YEAR

Although in a few cases the war seriously upset the plans of the executive committees for the season just closed, nevertheless on the whole the committees were able to maintain the development of the Sections organization and to carry out a progressive year's work. Naturally the meetings have changed in character somewhat and in a number of instances committees were called upon to fill programs quickly; many war subjects and war speakers have been introduced and much valuable information upon war topics brought out at the meetings.

In the last issue of The Journal were listed the more important papers contributed by the Sections. Some of these papers have already been published and others appear in this issue. While it is not yet possible to publish all the papers received and while it is likewise not yet possible to publish material immediately upon receipt, still the Publication and Papers Committee is alive to this condition and is considering ways and means of remedying it, so that the Sections may receive the prominence in the publications which their large contributions to the activities of the Society merit. Many of the papers presented before Sections are given in collaboration with local societies, and if the local society issues a publication, the paper appears in good season in the local journal. What we want is some arrangement whereby simultaneous publication of Local Sections papers may be made in the local journal and in the national journal, and then the interests of both societies will be best served.

The new executive committees, which, under the present method of government of Sections, assume office on July 1, are taking the opportunity afforded by the out-of-season period to familiarize themselves with the duties of their office and of laying their plans for the next year's work. In many cases the committees have already had their organization meetings. The transfer of records from the old to the new officers is now made in a very simple manner through the medium of what are called Section record books—loose-leaf binders with standard sheets which have been issued to each Section by the Committee on Local Sections and which contain just the information the chairmen and secretaries require in discharging their duties of office. This simple method saves a great deal of time when the personnel of the committee changes.

The thanks of the Society and of the members at large should be duly extended to the executive committees whose terms of office have just expired for the personal time they have devoted and the labor they have spent in continuing and fostering this fundamental activity. The amicable relations with local societies and with local groups of other national societies which were universally enjoyed by our Society are the subject of comment by all, and these relations are entirely due to the fine spirit with which the local committees have carried on their voluntary work.

As in previous years, the committees going out of office have been requested for brief reports of their activities for the year for publication in The Journal. Not all of these reports have yet come to hand, which is natural considering the heavy calls upon the time of every one. Those which have been received, however, are published in abstract below.

ATLANTA

The Section has continued to meet with the Affiliated Technical Societies of the City of Atlanta.

It was decided early in the year to hold meetings monthly and have a paper upon an appropriate subject presented at each meeting. This program was not quite carried out, however, owing to the war conditions.

The engineering paper of the year was entitled, The Effect of Fuel Economy of Different Arrangements of Baffles in Boiler Tubes, by Mr. W. G. Eager.

Oscar Elsas,
Section Chairman.

BALTIMORE

Six meetings were held this season, one being of the nature of a symposium of engineering problems of the canning industry.

At the November meeting a notable paper was read by Mr. W. L. De Baufre of the U. S. Naval Engineering Experiment Station on the subject of Evaporation. Professor Christie, at the same meeting, discussed the question of Municipal Ownership of Public Utilities.

At the May 22, 1918, meeting M. W. H. Blood, of the American International Shipbuilding Corporation, read a paper entitled Hog Island Shipyard; the Greatest in the World.

Wm. W. Varney,
Section Chairman.

BIRMINGHAM

The Section retained its affiliation with the Alabama Technical Association, which includes all members of the national engineering societies residing in the state of Alabama.

Five meetings were held, at three of which phases of the war situation were discussed. The May 16, 1918, meeting was an all-day joint meeting, at which Secretary Rice was present.

J. H. Klinck,
Section Chairman.

BOSTON

During the year the Boston Section held six regular meetings in addition to the Annual Dinner and a joint meeting with the A.I.E.E. Section. All these meetings were duly reported in THE JOURNAL.

The Annual Dinner of the combined engineering societies was held on April 30, and among the gentlemen who spoke were: Alfred D. Flinn, Secretary of the Engineering Council, who dealt with the Work of the Council; and W. H. Blood, Jr., of the American International Shipbuilding Corp., who delivered a lecture on Hog Island, the Greatest Shipyard in the World. Short addresses on subjects of the day were given by Major-General H. F. Hodges, in command at Camp Devens, and Major Andrew J. Peters, of Boston. Motion pictures were also shown illustrating the adaptability of a new rudder which has been perfected by H. O. Westendarp, of the General Electric Company.

The Annual Meeting of the Section took place at the Engineers' Club on the evening of May 29. Dr. Charles H. Eaton of the Shipping Board, Emergency Fleet Corp., delivered an address on America at the Gateway of Destiny.

No meetings have been planned for the summer months.

A. C. ASHTON,
Section Chairman.

BUFFALO

The Section has continued as an affiliated branch of the Engineering Society of Buffalo and has passed through its seventh season successfully.

The local society held a large number of meetings, many upon mechanical engineering subjects, all of which have been recorded in THE JOURNAL from time to time.

The new committee is a very active one and prospects for the coming year are exceedingly good. The committee already has some good papers in prospect.

F. E. CARDULLO,
Section Chairman.

CHICAGO

On October 24 a meeting of the executive committee was held with the Sections Committee who were visiting Chicago, and the question of coöperation with other societies in Chicago was discussed, which resulted in a movement to hold joint meetings with the Western Society of Engineers and the Chicago Section of the American Institute of Electrical Engineers.

The first regular meeting was held on November 16 in connection with the Council Meeting, and was attended by some 180 members and guests. The address was given by Lieut.-Col. Peter Junkersfeld on Cantonment Construction.

Three such meetings have been held, two in the rooms of the Western Society and one in connection with the meeting of the National Society for the Promotion of Engineering Education, at Northwestern University. At the first, Mr. C. F. Kettering spoke on the Development of the Internal-Combustion Engine, and at the second, Messrs. Berg and Morgan presented papers, the first on The Future Possibilities of Steam Economy, the second on Modern Condenser Practice.

The meeting at Northwestern University was on the subject of Technical Training for the War and After, and included short addresses on Present Needs of Industry, The Future Outlook, The Nature of Training Which Should Be Given, and The Employment of Women Workers in War Industries.

The March meeting of the Section took up the question of the fuel situation and addresses were given by Joseph Harrington and by Prof. H. H. Stock. Prof. Stock spoke on the question of Fuel Storage, and Mr. Harrington outlined the fuel situation and advocated a system of power-plant regulation such as is now being put in force by the Fuel Administration.

A short meeting held in May was addressed by John Erickson, City Engineer, who presented a paper on the New North-Side Tunnel and the Mayfair Pumping Station of the City Water Works.

Auxiliary activities of the Section during the year have been coöperation in the sending out of notices for the Government of requirements of engineers for Signal Corps Service, for the Refrigeration Regiment, for Submarine Service, and for the Ordnance Department.

The Section has also coöperated in the sale of the bonds of the Third Liberty Loan, and has joined with the other local sections and local societies of Chicago in establishing the War Committee of Technical Societies which is now issuing bulletins on Government needs, is coöperating with the State Fuel Administration in the power-plant census, and has held one popular summer meeting at which some 600 were present, addressed by S. J. Duncan Clarke on The Present War Situation in France.

A. D. BAILEY,
Section Chairman.

CINCINNATI

On October 18, 1917, Mr. F. O. Clements addressed a joint meeting of this Section with the Engineers' Club of Cincinnati on the Research Laboratory Applied to Industry. A brief abstract of this paper appeared in the December 1917 issue of THE JOURNAL.

Mr. J. E. Freeman was the speaker at the February 21 meeting and had for his subject the Construction of Concrete Ships and Barges.

A joint meeting with the Engineers' Club was held on the afternoon and evening of March 21, 1918. The afternoon session began at 2:30 and was presided over by George W. Galbraith. Mr. Henry Ritter, general superintendent of the Lunkenheimer Co., spoke on Shop Kinks, and the paper was discussed by A. Wood of the Niles Tool Works Co., Hamilton, and George Langen of the Cincinnati Planer Co. The second paper, on The Economic Use of Coal by Communities, was delivered by Prof. John T. Faig and was illustrated by lantern slides.

The evening session was presided over by the president of the Engineers' Club. Mr. C. U. Carpenter, vice-president and manager of works of the Recording & Computing Machines Co., Dayton, O., spoke of the training of some thousands of women, who had had no previous training in mechanical lines, for the manufacture of time fuses for Russian shrapnel.

At the meeting on May 11 the guest of honor was Secretary Calvin W. Rice, who delivered an inspiring address on the activities of the Society. Mr. F. A. Geier and Mr. George W. Galbraith also gave short talks.

An automobile trip to Dayton, O., was arranged for the members of the Section on May 25 and the party was given special permission to visit the famous Wilbur Wright Aviation Field near Dayton. During the afternoon, members were given an opportunity to inspect the plants of the Dayton-Wright Aeroplane Co. and the Recording & Computing Machines Co., the latter of which firms has accomplished much in its rapid and efficient method of training women for industry.

In response to a resolution offered by Dean M. E. Cooley of the University of Michigan before the Detroit Section, a committee was appointed by the chairman of the Cincinnati Section on the intensive training of women for industry, consisting of the following: George Langen, J. B. Doan and R. T. Hazleton. Through the efforts of this committee an intensive course in mechanical drawing was begun at the Ohio Mechanics' Institute, Cincinnati, on June 24. About forty young women presented themselves for this work and a number of them are now taking the places of men who have been called to the Service. It is the intention of the committee to continue its work.

G. W. GALBRAITH,
Section Chairman.

CONNECTICUT

The Connecticut Section, which was organized last year with five Branches at New Haven, Hartford, Bridgeport, Waterbury and Meriden, respectively, has passed through a successful season although all Branches have not been uniformly active.

It is felt that the work of the Section has been of service to engineers of the state and that as the organization develops this work will be enhanced in value.

The Connecticut plan provides for fall and spring meetings at New Haven and additional meetings at each of the Branches from time to time. Such meetings have been held this year.

Reports from all Branches have not yet come to hand, but the following typical report has been received from the Bridgeport Branch:

The Bridgeport Branch of the Connecticut Section has been coöperating with the other Branches in the state, copies of the

minutes of all executive meetings having been exchanged. They have also worked jointly with the New York Section and have been represented in the United Engineers' Sessions in New York City, and also on the Mayor of New York's special sessions for the Allied Engineering Societies, which had mainly to do with labor problems appertaining to mechanical engineering work. The Branch was also represented at a banquet given in honor of the British Labor Commission in New York.

The general meeting held on April 24, 1918, was most successful. This being a banner occasion, almost the entire membership was present. The combined meeting held on June 21 with the Bridgeport Manufacturers' Association and Chamber of Commerce was a particularly happy thought on the part of President Bilton, of the Manufacturers' Association. This last general meeting was a most successful affair and the papers read on the Conservation of Fuel will become a guide for carrying on this work.

Papers have not been as numerous as had been hoped possible but have been valuable, bearing on the subject of gages.

Henry B. Sargent,
Executive Committee Chairman.

DETROIT

Meetings of the Section are now being held in coöperation with the local sections of other societies and with the Detroit Engineers' Society in the rooms of the Chamber of Commerce.

The National Committee on Local Sections visited Detroit on October 25, 1917, when a few select brief papers were presented on primary topics.

The annual meeting was held on May 5, 1918, in conjunction with the Detroit Engineering Society. Important resolutions by Dean Cooley on the training of women for drafting-room work were adopted and transmitted to all engineering organizations.

The Detroit Section is looking forward with a great deal of anticipation to the coming of the Society to the city in the spring of next year and is already beginning to make arrangements for the distinguished guests.

G. W. Bissell,
Section Chairman.

ERIE

The Erie Section has continued its coöperation with the Engineers' Society of Northwestern Pennsylvania and held a joint meeting with the society on November 13, 1917. On May 3, 1918, Mr. James Burke presented a paper on The Conservation of Fuel.

The Section is still a young one, having only just passed through its second year of operation and that under the exceptional conditions of war.

J. F. Wadsworth,
Section Chairman.

INDIANAPOLIS

The Indianapolis Section has been coöperating with the Indiana Engineering Society, the local section of the A. I. E. E., and the local Chamber of Commerce.

An important joint meeting was held on June 25 of this year at which a number of papers of local and general interest were presented.

One other meeting was held on November 7, 1917, and was duly reported in The Journal.

A symposium on Fuel Conservation was held on May 10, 1918. Secretary Rice gave an address on The Relation of the National Society to the Section and the Relation of the Engineer to the War.

W. H. Insley,
Section Chairman.

LOS ANGELES

The Section has been coöperating with the joint technical societies of Los Angeles, which have been holding luncheon meetings throughout the year at which short talks have been given by speakers furnished by the various societies, in accordance with a program laid out in advance.

On November 24, 1917, an interesting visit by the societies was made to the top of Mt. Wilson and the Mt. Wilson Solar Observatory.

President Hollis visited the Section early in the year and also addressed the Student Branch at Throop Polytechnic Institute.

F. G. Pease,
Section Chairman.

MILWAUKEE

Milwaukee has just completed another good year, its meetings being largely attended. The meetings are still being held at the City Club.

The first meeting of the season was held on October 23, 1917, when the Section entertained the National Committee on Local Sections. Luncheon was served at the Milwaukee Club and a visit paid to the Allis-Chalmers plant. In the evening a large number of local engineers attended a dinner and took part in a discussion of Society affairs.

On November 14, Mr. B. E. Fernow gave an illustrated talk on the Design and Application of Magnetic Clutches. On January 16, 1918, Mr. W. Alexander spoke on Electric Locomotives on the Chicago, Milwaukee and St. Paul Railway. On February 13, 1918, Mr. E. S. H. Baars addressed the section on Cold Accumulators and Their Application to the Refrigerating Industry. A joint meeting with the Electricals was held on March 13 when Prof. C. M. Jansky spoke on Science in War. A successful meeting was held on April 10 under the auspices of the American Society of Refrigerating Engineers, and C. L. Portier gave an illustrated lecture on Automatic Control Apparatus for Temperature. On May 8 Mr. N. J. Whelan addressed the Section on The White Coals of Wisconsin.

W. M. White,
Section Chairman.

MINNESOTA

A very cordial feeling exists between the Minnesota Section and the other engineering interests and societies of the state. The Minnesota Joint Engineering Board is becoming a factor in society affairs in the Northwest. The Board has headquarters in the Twin Cities and practically all the engineering associations in the state have applied for membership in it.

The Board recently appointed a committee to draw up a permanent plan of organization of an engineering club. Four alternatives are under consideration: (1) An all-inclusive organization for professional engineers, juniors and associates, with a different status for each, (2) an organization of members of the four national societies, (3) an organization of national society members with a limited number of associate members, (4) an organization of professional engineers only.

Three elements are considered as essential to the organization: professional, social and civic; and it has been suggested that affiliation be made with a civic body so that the entire community may be bettered.

A joint meeting of the sections of the national societies was held in Duluth on May 20.

H. LeRoy Brink,
Section Chairman.

NEW ORLEANS

The second year's work of the New Orleans Section has been a successful one. As before, meetings have been held in entire coöperation with the Louisiana Engineering Society.

Five meetings were held during the season. On September 7 Mr. F. J. French read a paper on Shipbuilding which was published later in The Journal. The January 12, 1918, meeting was a smoker with the Louisiana Engineering Society. On February 11, 1918, Mr. P. E. Lehde gave an address entitled, Some Notes on Wireless Telegraphy, and on March 11 Mr. A. M. Lockett described the New Orleans Industrial Canal. On May 13 Secretary Rice visited the Section, and Hon. T. F. Carlisle, British Consul, spoke on Britain and the War during the last twelve months.

H. L. Hutson,
Section Chairman.

NEW YORK

During the first half of the season the plans of the Section were somewhat disorganized on account of the almost complete dismem-

[illegible] E. [illegible] Ar[illegible] considerable effort [illegible] organized and aggressive program [illegible] [illegible].

Report [illegible] meeting held has been published in full in THE JOURNAL, the discussion at the meeting on Non-Essential Industries on February 21, 1918, being given place by the Publication Committee in the technical section.

On April 9, 1918, a unique gathering was held in the form of a joint meeting of the Metropolitan Student Branches and the New York Section. The Branches were responsible for the conduct of the meeting and carried the program through in a very creditable manner.

JOHN H. NORRIS,
Section Chairman.

ONTARIO

This section was established in May of last year.

On January 29, 1918, Mr. F. B. Ward addressed the Section on the Influence of Munition Manufacture and Other War Work on Machine-Shop Practice. On March 25 a meeting of the Joint Committee of Technical Organizations was held and several speakers addressed the Section on war subjects. On April 18, 1918, Mr. W. M. Wilkie spoke on Heat Treatment of Low-Carbon Steels.

A well-attended meeting of the A.S.M.E. Ontario Section and the Toronto Branch of the Engineering Institute of Canada was held in the lecture room of the Engineers' Club on July 3, at which two subjects were presented.

The first was a very interesting paper by Edward Maybee on Patents of Invention which covered particularly that part of the patent field of interest to engineers, and a number of points which are generally not well understood were explained very clearly.

The second subject was an address by Mr. Holmes, of the Invalid Soldiers' Commission, on The Training of Disabled Soldiers in the Industries. The training of returned soldiers falls into three periods: that in the hospitals, then in the reëducation schools, and lastly in the shops of the industries themselves. Mr. Holmes dealt with this last department and explained the organization and methods of handling the work. It is with this industrial phase of the training that the engineers and employers should be most closely in touch, because here they can help most.

Mr. Holmes explained how the preliminary survey is made of each plant before men are placed there and that a careful supervision is kept over the men and their work by the government commission during the period of their instruction. The men receive pay from the government and instruction from the firm. Over 90 per cent of the men so placed have made good and are now earning or making good progress toward earning, a comfortable income.

The principal point brought out was that the returned men should not be dumped upon the industrial field and left to shift for themselves, but that their cases must be studied individually and the men allotted to positions suiting not only each man's natural capacity but also the nature of his wounds or physical deficiency.

R. W. ANGUS,
Section Chairman.

PHILADELPHIA

Early in the fall of 1917, the Executive Committee met and arranged the entire program for the year, completing all arrangements by the middle of September. In spite of the pressure of war work, none of the speakers failed to keep his appointment, much to the gratification of the committee and the membership.

On October 16 the first meeting of the year was held jointly with the Philadelphia Engineers' Club in Witherspoon Hall. President Vogelson of the Engineers' Club presided. Mr. Homer L. Ferguson, President and General Manager of The Newport News Shipbuilding & Dry Dock Co., gave an excellent address upon The War's Effect on Merchant Shipbuilding. At the time of this meeting the country had just become awakened to the necessity and importance of the shipping program; his address, therefore, was a very timely one. About six hundred engineers from Philadelphia and vicinity attended the meeting.

The meeting of November 2 was given over to a discussion of the activities of the Local Sections of the Society. Mr. D. Robert Yarnall, the chairman of the National Committee on Sections, opened the meeting with a statement in which he emphasized the fact that some of the newer western Sections have been extremely active and progressive, and that Philadelphia would have to use every possible means to equal the pace set by the western Sections. The Local Section had the pleasure of meeting at this time Ernest Hartford, Secretary of the Committee on Sections, and William Bullock, Assistant Secretary of the Society. Professor Walter Rautenstrauch, of Columbia University, gave the leading paper of the evening, entitled Manufacturing in Relation to Banking, Research and Management.

On December 11 a paper entitled Offensive Against the Submarine was presented by Joseph A. Steinmetz at a joint meeting of the Franklin Institute and the A. S. M. E., held in the Franklin Institute Auditorium. The lecture was fully illustrated with lantern slides and moving pictures.

On January 22 The War on Land and Sea was discussed at the Engineers' Club by Professor Cathcart, who is a retired officer of the United States Navy and has studied the situation closely. In introducing the subject, Professor Cathcart said:

"It may be safely said that the present war has had no parallel since the darkest days of barbarism. Prussian autocracy is the enemy of no one nation or group of nations, but of all free peoples the world over. For forty years that savage government has made deliberately planned war for world-dominating aims the chief industry of its subjects. To further these aims, in their political and financial bearing, sinister German intrigue has been active everywhere. From Bagdad to Buenos Aires there is no land now which is not stained by the slime of German plotting, of German money lavishly spent for basely treacherous ends."

A lecture that was quite new in its field was given by Carl G. Barth on February 26. Mr. Barth took as his subject The Income Tax, an Engineering Analysis, in which by a thorough mathematical analysis of the Federal Income Tax law, represented graphically in several ways, he clearly set forth the defects of this law. Mr. Barth has promised at a later date to give to the Philadelphia Section a supplement to The Art of Cutting Metals. This work of the late Dr. Frederick W. Taylor is well known as a masterpiece on the subject. A revision of the work by a man of Mr. Barth's experience is looked forward to eagerly by the engineering fraternity.

Few men realize the very important part that the Bureau of Standards has taken in the war. Dr. S. W. Stratton, director of the Bureau, stopped his work long enough to visit Philadelphia and deliver to a very large audience in Witherspoon Hall on March 27 a paper on The Relation of the Bureau of Standards to the War. Views and descriptions of very delicate measuring instruments used by Dr. Stratton in his work were shown.

On April 23 the Section had the pleasure of entertaining the Council of the National Society at a dinner meeting held in the Adelphia Hotel, Philadelphia. The following members of the Council attended: Messrs. Rice, Benjamin, Plunkett, Orrok, Marburg, Thomas, Green, Rautenstrauch, Hartness, Wiley, Alford, Stevens, Main and Barr.

George Satterthwaite, vice-president and general manager of the Tacony Ordnance Corporation, spoke on May 28 to a large audience in the Engineers' Club auditorium. Mr. Satterthwaite's subject was the Manufacture of Ordnance Forgings. Supplementing Mr. Satterthwaite's paper a moving-picture film giving in detail the manufacture of 9.2 high-explosive projectiles was shown. These films were loaned through the courtesy of *Machinery* and the Industrial Press.

The following were elected officers for the year beginning July 1, 1918: C. N. Lauer, chairman; John P. Mudd, secretary; H. B. Taylor, L. F. Moody, W. B. Murphy and L. H. Kenney for executive committee.

During the year 1917-1918 four joint meetings were held with other engineering societies in Philadelphia. The joint-meeting idea is a good one, and it is the hope of the Local Section that there will be more of the "get together" among the numerous engineering societies in Philadelphia.

Three papers presented at meetings of the Philadelphia Section this year have been published in THE JOURNAL of the Society, and four have been published in the *Journal* of the Engineers' Club. The paper presented by Homer L. Ferguson on The War's Effect on Merchant Shipbuilding was also published in the *Marine Review*, and extracts of it were printed in several other trade journals.

L. F. MOODY,
Section Chairman.

PROVIDENCE

As heretofore, the functions of the Local Section at Providence are accomplished through an affiliation with the Providence Engineering Society. The local society has made uniform progress during the past year and is now well established in its adequate and permanent quarters. The activities of the local committee have been continued under the fire-insurance, designers' and draftsmen's section, machine-shop, efficiency, structural engineering, chemical, power, municipal, highway and water supply, industrial and technical education, student, and municipal engineering sections. Each section held meetings monthly at which papers on suitable technical topics were presented and discussed.

The annual outing of the Providence Engineering Society together with the American Chemical Society was held at the Oakland Beach Yacht Club on June 29. Many attractions and sports were arranged and all in attendance had a very enjoyable time.

Robert W. Adams, *President,*
Providence Engineering Society.

ST. LOUIS

There has been a growing feeling in St. Louis that considerable attention should be paid in the Section to subjects touching upon the human side of engineering work. Accordingly, at the first meeting this year, September 21, a number of vital-interest questions to mechanical engineers in St. Louis were discussed by prominent members, all of whom indicated very clearly that there was a large amount of work laid out for the coming year and that it was to be carried forward with great earnestness. This idea was confirmed by the visit of President Hollis the next month, who emphasized this policy as the first and foremost one of service to the engineering profession.

Six regular meetings of the Section were held during the year. The November 23 meeting was in the form of a testimonial dinner tendered to Mr. John Hunter by the Associated Engineering Societies of St. Louis, which was reported in The Journal.

An exceedingly timely meeting was that held on March 29, 1918, when Dr. Isaac Lippincott addressed the Section on Economic Reconstruction After the War.

R. L. Radcliffe,
Section Chairman.

SAN FRANCISCO

The meetings have taken the form of joint meetings of the sections of the Mechanical, Civil, Mining and Electrical Engineers, and the American Chemical Society. At the first of these joint meetings, on October 25, 1917, a dinner was tendered to President Hollis on the occasion of his visit to the Pacific Coast. The general subject for the evening was the Relation of Engineering to the War and speakers from each society took up the particular branch of engineering represented by his society. Doctor Hollis responded with an inspiring address on the Moral Influence of Engineering and Efficiency.

A similar joint meeting with four speakers on war topics was held on March 20, 1918.

B. F. Raber,
Section Chairman.

WORCESTER

The biggest event in the Worcester Section this year was the Spring Meeting of the Society held there from June 4 to 7, 1918. This has been fully reported in The Journal. Most of the activities for the year were taken up in the preparation of plans for this meeting and their execution.

On November 22, 1917, President Hollis and Prof. L. P. Breckenridge opened a discussion upon Fuel Conservation.

George I. Rockwood,
Section Chairman.

ROLL OF HONOR

Appelquest, J. A., Second Lieutenant, Aviation Section, N. A.

Bassett, Cyrus W., Corporal, Headquarters Co., 305th Ammunition Train, American Expeditionary Forces, France.

Bayne, George H., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army.

Bickley, C. D., Second Lieutenant, Utility, Quartermaster Corps, U. S. Army, Camp Dix, N. J.

Blee, H. H., Captain, Air Service, U. S. Army, Airplane Engineering Department, Bureau of Aircraft Production, McCook Field, Dayton, O.

Bolton, Wright, Jr., Chief Machinist's Mate, U. S. Naval Aviation Station, France.

Bryce, Richard M., Ordnance Corps, U. S. N. A., American Expeditionary Forces, France.

Corp, Charles I., Captain, Sanitary Corps, U. S. Army, assigned to Fort Oglethorpe, Ga.

Deeds, Edward A., Colonel, Signal Corps, U. S. Army, assigned to Washington, D. C.

Doar, E. Marion, Machinist's Mate, U. S. Navy, Candidate Steam Engineers' School for Officers, Stevens Institute of Technology, Hoboken, N. J.

Donaldson, Harold R., Flying Cadet, Barracks No. 54, Kelly Field No. 2, San Antonio, Tex.

Dunton, Philip R., Sergeant, Tank Corps, Headquarters Co., 326 Battalion, Camp Colt, Gettysburg, Pa.

Durgee, Andrew B., First Lieutenant, Air Service Department, Military Aeronautics, Taliaferro Field, Hicks, Tex.

Eager, W. G., Lieutenant, Senior Grade, U. S. Naval Reserve Force.

Flad, Albert E., Marine Reserve Flying Corps, Navy Yard, Philadelphia, Pa.

Flanigan, Edwin B., First Lieutenant, Quartermaster Corps, U. S. Army, commanding M. S. T. U. 405, American Expeditionary Forces, France.

French, E. V., Major, Quartermaster Corps, N. A., American Expeditionary Forces, France.

Gill, Murray F., 5th Officers' Training Camp, Fort Monroe, Va.

Grady, William H., Candidate, Officers' Training Camp, Camp Zachary Taylor, Ky.

Grisbaum, L. D., U. S. Naval Reserve Force, Marine Engineers' Training School, Hoboken, N. J.

Harrison, H. L., Ensign, U. S. Naval Reserve Force, Navy Department, Bureau of Ordnance, Washington, D. C.

Hood, Warren B., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army, assigned to Watertown Arsenal, Watertown, Mass.

Hoover, A. Pearson, Major, Quartermaster Corps, N. A., assigned to Boston Quartermaster Terminal, Boston, Mass.

Hyde, G. C., Captain, Utility Detachment, Camp Beauregard, Alexandria, La.

Karr, Alfred D., Second Lieutenant (military aeronautics), Signal Corps, N. A., Air Service Flying School, Chanute Field, Rantoul, Ill.

Klinck, J. H., Major, Quartermaster Corps, N. A.

Kossif, N., Cadet, U. S. School of Military Aeronautics, Mass. Inst. Tech., Cambridge, Mass.

Lafore, John A., Major, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army, assigned to Washington, D. C.

Langstroth, C. B., Captain, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army.

McLundie, Archibald S., First Lieutenant, Ordnance Officers' Reserve Corps, Rock Island Arsenal, Rock Island, Ill.

Miller, H. W., Captain, Railway Artillery Section, Ordnance Department, U. S. Army, American Expeditionary Forces, France.

Murphy, E. A., Second Lieutenant, Aviation Section, N. A., Bureau of Aircraft Production, Purchase Division.

Nichols, George B., Captain, 56th Engineers, Washington Barracks, District of Columbia.

Ruddy, William, First Lieutenant, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army.

Terry, Carlyle M., Chief Machinist's Mate, U. S. Naval Reserve Force, Steam Engineering School, Pelham Bay, N. Y.

Thompson, Herbert L., Ensign, U. S. Naval Reserve Force.

Turner, Robert T., Corporal, 52d Pioneer Infantry, U. S. Army, Camp Wadsworth, Spartanburg, S. C.

Tuttle, W. B., Major, Construction Division, Quartermaster Corps, N. A.

NECROLOGY

EDWARD R. ARCHER

Edward R. Archer was born on March 9, 1834, at Old Point Comfort, Va. He received his early education in the private schools of Hampton and Richmond, Va., and at the age of 17 entered the employ of the Tredegar Iron Works of the latter city, where he served an apprenticeship of four years in the shops and drafting room of that company. On June 26, 1856, he was appointed third assistant engineer in the U. S. Navy and served in that capacity on the U. S. Frigates *Roanoke* and *Powhatan*, making a two and a half years' cruise around the world. At the close of the cruise he returned again to the Tredegar Iron Works and remained in their employ until the outbreak of the Civil War, when he entered the service of the Confederate Navy. When peace was declared he again reëntered the employ of the Tredegar Iron Works, and at the time of his death was chief engineer of the company.

In addition to being a member of our Society since 1890, Mr. Archer was one of the founders of the Virginia Mechanics Institute. He died at his résidence in Richmond on March 13, 1918.

EDWARD CARRINGTON BATES

Edward C. Bates was born in Boston, Mass., in 1848. He was educated in the private schools of that city, preparatory to attending Brattleboro Academy, after which he went to the Massachusetts Institute of Technology where he was graduated with the first class sent forth, that of 1868.

He then began work in his chosen profession as civil and railroad engineer and on going West was active in the earliest days of the Union Pacific Railway. During his career he held the position of superintendent of works of the Union Electric Sign Signal Co., Boston, and the same later with the Union Switch & Signal Co., Pittsburgh. He was for five years superintendent with the Hall Typewriter Co. and for eleven years railroad representative for the Crosby Steam Gauge & Valve Co., Boston. He was also associated for a period with the Ewald Iron Co., St. Louis.

Mr. Bates was an inventor of note and his later years were devoted to inventing although in a less active way than formerly. He became a member of our Society in 1899. He died very suddenly on July 23.

CHARLES HARVEY HILE

Charles H. Hile was born at Bellefonte, Pa., in March 1864. He was graduated from Pennsylvania State College in 1892 with the degree B.S. and in 1893 he received the degree of M.E. from the University of Wisconsin.

He then entered the employ of the Philadelphia Traction Co., first as electrical assistant, then as engineer and inspector of underground conduit construction and later as operator in the power station. In July 1894 he entered the employ of the West End Street Railway Co., Boston, Mass., and served continuously with that company and its successor, the Boston Elevated Railway Co., for twenty-two years. During his long career with the two Boston companies, he won rapid promotions, being successively assistant superintendent of wires, superintendent of wires, assistant to the vice-president and chief of maintenance. In the last-named position he was in charge of the departments of mechanical and electrical engineering, maintenance of way, rolling stock and shops, building, stores, wires and conduits and power maintenance. Impairment of health finally required him to relinquish these heavy responsibilities and the company gave him an indefinite leave of absence with the privilege of engaging in lighter and less nerve-racking duties. In 1916 he became the secretary of the New England Street Railway Club, Boston, Mass. He was also editor of the publications of the club, *The Street Railway Bulletin* and the *Trolley Wayfinder*.

He became a member of our Society in 1916. He died on June 4.

HARRY C. HOLCK

Harry C. Holck was born in June 1887 in New York City. He received his technical education in the Carnegie Technical School, after which he entered the employ of the Keuffel & Esser Co., Hoboken, N. J., as assistant to the chief engineer. In 1908 he became connected with the George A. Ohl Co., Woodside, N. J., where he installed a drafting-room system and took charge of the design of their power presses and embossing machines. The following year he entered the employ of the Niles-Bement-Pond Co., Plainfield, N. J., as a designer, and while with this firm successfully designed a car-wheel lathe to turn car wheels at the rate of two in four minutes. In 1910 he became associated with the General Electric Co., Schenectady, N. Y., as engineer and designer of A. T. B. generators and synchronous and induction motors.

For the next three years he was employed successively by the Otis Elevator Co., New York City, as construction engineer for freight and passenger elevators; by the Regina Co., Rahway, N. J., as assistant to chief draftsman in systematizing and developing the design of a multi-process printing press; and by the Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa., as engineer on control apparatus, rheostat, switchboards and oil switches. In 1913 Mr. Holck became connected with the Public Service Electric Co., Newark, N. J., where he was engaged in the design and engineering of sub-stations and central stations, system of railways and lighting distribution, and developed one of the largest and most modern stations in the East.

At the time of his death, June 13, he was employed as engineer and electric designer in the engineering department of the company. Mr. Holck became a junior member of the Society in 19[illegible].

JOHN DOLAN GABOURY

John D. Gaboury was born in Knoxville, Tenn., on June 3, 1879. Upon the completion of his collegiate education be took two years' special course in mathematics at St. Charles Barrome College, Sherbrooke, Quebec, Canada, and followed this in 1895 with a six months' special course in applied electricity at McGill University, Montreal.

Until about 1897 he was associated with his father who was one of the pioneer electric contractors and power-plant operators in the South. His next position was with the Greenville Light & Power Co., Greenville, Miss., as engineer, where he remained until 1905, holding successively the positions of electrician and superintendent. In 1905 he became connected with the Alabama City, Gadsden & Attalla Railway Light & Power Co., Attalla, Ala., as general manager and remained with them for a little over two years, during which time he designed and built a modern condensing steam-turbine power plant for lighting and railway service. In 1907 he entered the employ of the Woodward Iron Co., Woodward, Ala., as electrician, later becoming chief electrical engineer and finally superintendent of power, which position he had been holding for the last four years. The company makes approximately 1500 tons of pig iron per day, furnishing all of its own raw material. This involves the operation of several coal mines, red-ore mines, coal washers, by-product coke plants and a steam railroad for the transportation of raw material to the furnace plant. Mr. Gaboury was entirely responsible for the design, construction and operation of all the power-plant equipment, steam and electric hoists, haulage, rolling stock, steam and electric, as well as all of the repair work involved.

Mr. Gaboury became an associate-member of the Society in 1917 and was particularly active in the affairs of the Birmingham Section. He was also an associate-member of the American Institute of Electrical Engineers. He died very suddenly on May 17.

GEORGE E. WHITEHEAD

George E. Whitehead was born on September 6, 1846, at Ashton-under-Lyne, Lancashire, England. He was brought to this country when but a child and was educated in the public schools of Providence, later taking a special course in mathematics at the Jenks Morey School of that city.

During the period of the Civil War Mr. Whitehead was employed by the Burnside Rifle Works Co., leaving at the close of the war to serve his apprenticeship as mechanic with the Brown & Sharpe Manufacturing Co., Providence, R. I., at the same time completing his studies in algebra, geometry and trigonometry. He was next employed by the Household Sewing Machine Co., as tool maker and die cutter. In 1874 he became associated with the Rhode Island Tool Co. as assistant superintendent and later became superintendent, serving in that capacity for thirty-one years.

Mr. Whitehead became a member of the Society in 1887. He died on March 4, 1918.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

BOOK NOTES

Elements of Fuel Oil and Steam Engineering: A Practical Treatise Dealing with Fuel Oil, for the Central Station Man, the Power Plant Operator, the Mechanical Engineer and the Student. By Robert Sibley, B. S., and Charles H. Delany, B. S., M. M. E., Members Am.Soc.M.E. Technical Publishing Company, San Francisco, 1918. First Edition. Cloth, 6 x 9 in., xiv + 320 pp., 127 illustrations, charts and figures. $3 net.

This book has as its underlying theme a study of fuel-oil power-plant operation and the use of evaporative tests in increasing the efficiency of oil-fired plants. The subject-matter has been treated in three main subdivisions: First, an exposition of the elementary laws of steam engineering; second, the processes involved in the utilization of fuel oil in the modern power plant; and third, the testing of boilers when oil-fired.

A new method has been used in treating the first subdivision, in that the viewpoint taken is that of the oil-fired instead of the coal-fired power-plant operator. This subdivision naturally requires the largest portion of the work.

The five chapters on Furnaces, Burner Classification, Gravity, Moisture Content, and Heating Value of Oils contain the gist of the information which will be of value to the inexperienced engineer whether he views the subject from a consulting or operating standpoint. The engineer who has had considerable experience in this line will be interested in the chapters on Suggestions for Fuel-Oil Tests and Their Tabulation, and the Use of Evaporative Tests in Increasing Efficiency of Oil-Fired Boilers, as these chapters, especially the latter, contain definite information worked out from practical experience in regard to furnace arrangement, oil burners, draft, flue-gas analysis and regulation.

The most interesting part to the experienced fuel-oil engineer is Appendix 2, which contains the report of conclusions in full of the Committee appointed by the Governor of California, in the latter part of 1917, to investigate the fuel-oil situation in that state and report their conclusions and recommendations. These conclusions cover utilization, production, consumption, storage, conservation and the remedy for the present shortage of oil in California. This is a remarkable report which should be read by every engineer interested in the future of fuel oil in this country.

We believe the authors have succeeded admirably in accomplishing the purposes which the book attempts to cover. It is unquestionably the best work of its kind for students of steam engineering who are interested in fuel oil. It is also of value to engineers, both consulting and operating, as it gives a large amount of information hitherto not covered by any work of this kind, and at the same time brings together much important matter which has appeared at various times in various forms. The subject-matter is clearly developed, and illustrated examples are worked out in great detail. The book is also profusely illustrated. To sum up, we believe this work occupies a field hitherto vacant in this particular branch of engineering.

B. R. T. Collins.

Edible Oils and Fats. By C. Ainsworth Mitchell. Longmans, Green and Co., New York, 1918. Cloth, 6 x 9 in., 159 pp. $2.

A concise outline of the chemical composition, and properties of the more important oils and fats, the methods of extracting them from the crude materials and of purifying and preparing them for food. Particular attention is given to the newer methods. A very full bibliography is appended to the text.

Concrete Engineers' Handbook. Data for the Design and Construction of Plain and Reinforced-Concrete Structures. By George A. Hool and Nathan C. Johnson, assisted by S. C. Hollister, with chapters by Harvey Whipple, Adelbert P. Mills, Walter S. Edge, A. G. Hillberg, and Leslie H. Allen. First edition. McGraw-Hill Book Co., Inc., New York. 1918. Flexible cloth. 6 x 9 in., 885 pp., illus., tables, diag. $5.

This work has been prepared to make available in concise form the best present knowledge concerning concrete and reinforced concrete, and to present complete data and details, as well as numerous tables and diagrams, for the design and construction of the principal types of concrete structures.

The Cyanide Process. Its Control and Operation. By A. W. Fahrenwald. First edition. John Wiley and Sons., Inc., New York, 1918. Flexible cloth, 4 x 7 in., 256 pp., 37 illus., 1 folded pl., 1 folded chart, 27 tables. $2.

The object of the book is to furnish a laboratory guide, both for investigating a new ore and for conducting the laboratory of a mill, which will include the latest developments of the process and be sufficiently complete for ordinary needs.

Diseases of Occupation and Vocational Hygiene. Edited by George M. Kober and William C. Hanson. P. Blackiston's Sons and Co., Philadelphia (copyright, 1916). Cloth, 6 x 10 in., 918 pp., 46 illus. $8.

With the assistance of a large number of experts, the editors have endeavored to present the basic facts concerning diseases of occupation in such a way as to form a safe, convenient guide for physicians, employers, workmen, legislators, public health officials and other interested persons.

Engineering for Masonry Dams. By William Pitcher Creager. First edition. John Wiley and Sons, Inc., New York, 1917. Cloth, 6 x 9 in., 237 pp., 88 illus., 1 pl., 25 tables. $2.50.

Contents: Investigations and Surveys, The Choice of Type of Dam, Forces Acting on Dams, Requirements for Stability of Gravity Dams, General Equations for Design of Gravity Dams, The Design of Solid, Non-overflow Gravity Dams, The Design of Solid Spillway Gravity Dams, The Design of Hollow Dams, The Design of Arch Dams, Preparation and Protection of the Foundation, Flood Flows, Details and Accessories. Presents the theory and the fundamental assumptions of design of dams of this kind, and gives a number of examples showing the application of theory to practical designing.

Glossaire, (Anglais-Français) des Termes et Locutions Electro-Techniques les Plus Usites. Compilé par Aristide Filiatreault. M. J. Filiatreault, Montreal, 1913. Paper, 4 x 7 in., 59 pp.

A moderate priced English-French electrical dictionary of pocket size.

How to Sell Electrical Labor-saving Appliances. One hundred and nineteen tested Plans for the Electric Store. Window Display. Show Cases, Shelves and Tables. Arrangement. Advertising. Prospects. Demonstrations. Training Clerks. Planning Sales. Management. Compiled by Electrical Merchandising. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 5 x 8 in., 115 pp., 15 illus., 13 pl. $1.

A manual for dealers in electrical supplies and fixtures,

suggesting methods for displaying stock, advertising, training clerks, etc.

Industrial Reconstruction. A Symposium on the Situation after the War and How to Meet It. Edited by Huntly Carter. E. P. Dutton and Co., New York, 1918. Cloth, 5 x 7 in., 295 pp. $2.

Contains the results of an inquiry undertaken to ascertain the opinions held by a large number of distinguished English men and women as to the probable industrial situation in Great Britain after the war and the best policy to be pursued by Labor, Capital and the State. The views of statesmen, capitalists, labor leaders, economists and others are included.

International Mining Law. By Theo. F. Van Wagenen. First edition. McGraw-Hill Co., Inc., 1918. Flexible cloth, 5 x 7 in., 342 pp. $3.50.

Starting with an account of ancient mining laws and customs, the author gives a digest of the present mining laws of the world. Statistics of production in the leading countries are given to show the effect of various laws on the industry, and there are discussions of different features of the laws. Confined to metal mining; the laws having to do with coal, iron and non-metals are omitted.

Organic Compounds of Arsenic and Antimony. By Gilbert T. Morgan. Longmans, Green and Co., New York, 1918. Cloth, 6 x 9 in., 376 pp., $4.80.

This volume in Messrs. Longmans' series of Monographs on Industrial Chemistry discusses the methods of preparation and the chemical properties of those compounds which have a practical application or theoretical interest. A useful bibliography is included.

War Adjustments in Railroad Regulations. Edited by C. H. Crennan. The American Academy of Political and Social Science, Philadelphia, 1918. (Annals of the American Academy of Political and Social Science, vol. 76. Whole number, 165. March, 1918.) Paper, 7 x 10 in., 333 pp., $1.

In this number of the Annals is presented a discussion, by a number of railroad men, political economists and lawyers, of various problems connected with railroad regulation.

The principal headings are: Railroad Regulation on Trial, War Pressure for Adequate Service, Present Effects of War Control of Railroads, Plans for Adjustment after the War, Continuing Problems of Public Policy, in addition to a chapter entitled Documents and Statistics Pertinent to Current Railroad Problems.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER SEPTEMBER 21

Below is the list of candidates who have filed applications since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of applications 198.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by Sept. 21, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

BUBAR, Hudson H., Mechanical Superintendent, Air Nitrates Corp., Muscle Shoals

KENT, J. F., Manager, American Cast Iron Pipe Co., Birmingham

Arizona

HOFF, Edward A., Construction Engineer, United Verde Copper Co., Clarkdale

California

TURNER, Alfred J., Lubricating Oil Engineer, Standard Oil Co., San Francisco

Connecticut

ASHMUN, Bernard L., Vice-Pres., Pratt & Cady Co., Hartford

CAREY, H. Bissell, M. S. Little Mfg. Co., Hartford

LITTLE, Mitchell S., Manufacturer, M. S. Little Mfg. Co., Hartford

MORHARDT, Frank W., Mechanical Superintendent, Royal Typewriter Co., Inc., Hartford

PAINE, Walter S., Safety Engineer, Aetna Life Insurance Co., Hartford

QUINN, Lawrence R., Captain, Ord. R. C., U. S. A., Scovill Mfg. Co. Waterbury

VANDE PLANCKE, George, Superintendent, Turner Machine Co., Danbury

Delaware

LINDSAY, William J., Engineer, E. I. du Pont de Nemours & Co., Wilmington

District of Columbia

CHASE, Arthur H., Supervising Draftsman, U. S. Naval Gun Factory, Navy Yard

MARZOLF, Joseph M., Mechanical Expert, Aid Bureau of Yards & Docks, Navy Department

Florida

HAWKES, John D., Construction Work, Buckman & Pritchard, Pablo Beach

KENNEDY, Sidney G., General Foreman, Atlantic Coast Line R. R. Co., Lakeland

Georgia

CLIFFORD, Walter, General Supt., Atlantic Paper & Pulp Co., Savannah

Illinois

ADAMS, Ernest H., Mechanical Engineer, Continental Can Co., Chicago

CHANDLER, Albert R., Captain, Ordnance Reserve Corps, Rock Island Arsenal

DRATZ, Paul A., Chicago Representative, Whiting Foundry Equipment Co., Harvey

GALLUP, Rockwell L., Head of Engineering Dept., Torris Wold & Co., Chicago

KNAPP, Charles S., Assistant Chief Engineer, Pullman Co., Chicago

MILLER, Edward W., Chief Engineer, Fellows Gear Shaper Co., Springfield

Indiana

HUTCHCRAFT, D. L., Vice-Pres., Indiana Air Pump Co., Indianapolis

Kansas

SIMMERING, Siebelt L., Assistant Professor, Steam and Gas Engineering, Kansas State Agricultural College, Manhattan

Maine

FOWLES, Frank R., General Superintendent, York County Power Co., Biddeford

Maryland

WHITSITT, William B., Chief Draftsman, Baltimore & Ohio R.R., Motive Pwr. Dept., Baltimore

Massachusetts

BANFIELD, Frederick E., Jr., Superintendent, Saco-Lowell Shops, Newton Upper Falls

BATH, John, Owner, John Bath & Co., Inc., Worcester

BINNS, Frank, Draftsman, Hamblet Machine Co., Lawrence

DRAKE, Alden M., Chief Designer, Heald Machine Co., Worcester

EAMES, Jesse J., Instructor, M. E. Dept., Mass. Institute of Technology, Cambridge

KEEDY, Dyke V., Consulting and Metallurgical Engineer, Boston

KNIGHT, ARTHUR, Gage Design and Tolerance Engineer, Greenfield Tap & Die Corp., Springfield
LYLE, ERNEST T., New England Manager, Carrier Engineering Corp., Boston
ROOT, FRANCIS S., Power Engineer and Head of Pwr. Dept., Fall River Electric Light Co., Fall River
WITMER, ROY C., Secretary and General Manager, Blake Pump & Condenser Co., Fitchburg
ZSCHOKKE, ARTHUR J., Assistant Principal Draftsman, Watertown Arsenal, Watertown

Michigan

BAUS, RICHARD E., Assistant General Production Manager, Studebaker Corp., Detroit
BRITTSON, L. E., Major Ord. R. C., Inspector Ord., Ford Motor Car Co., Detroit
HARRIS, EMERY E., Vice-Pres., Pittelkow Heating & Engrg. Co., Detroit
HAWES, FRED W., Superintendent Wheel Dept., Detroit Pressed Steel Co., Detroit
LANE, HORACE H., Consulting and Designing Engineer, Detroit
McDONALD, William F., Heating Engineer, William F. McDonald Co., Detroit
PITTELKOW, ARTHUR G., President, Pittelkow Heating & Engrg. Co., Detroit

Missouri

FARNHAM, DWIGHT T., Consulting Industrial Engineer, St. Louis

Montana

PRUETT, GROVER C., City Engineer and Superintendent Water Works, Miles City

New Jersey

EPPENSTEIMER, WILLIAM F., Mechanical Engineer, United States Metals Refining Co., Chrome
FOX, AUBREY E., Industrial Engineer, Celluloid Co., Newark
McINTYRE, MALCOLM, Vice-Pres., Bergen Point Iron Works, Bayonne
MEIGS, WILLIAM P., Works Manager, Magor Car Corp., Passaic
RICHARDSON, HENRY, President, Richardson Scale Co., Passaic
SCHULHOFF, SAUL, Asst. Production Manager, Essex Rubber Co., Trenton
STENGER, JOHANNES G., Chief Draftsman, Marine Dept., Babcock & Wilcox Co., Bayonne
WOOD, HENRY E., Instructor of Special Mechanical Workers, Crocker-Wheeler Co., Ampere

New York

AXELSSON, GUSTAF S., Mechanical Engineer, Otis Elevator Co., New York
BLINN, EDWARD R., Superintendent of Construction and Maintenance, The Solvay Process Co., Syracuse
BRENNAN, JOHN E., Assistant Works Manager, The Remington Arms Union Metallic Cartridge Co., Inc., Ilion
CARMODY, JOHN P., Mechanical Engineer, Perin & Marshall, New York
CEBRAT, PAUL, Estimator and Purchasing Engineer, C. P. Perin & S. M. Marshall, New York
DISBROW, WILLIAM C., JR., Private Business, New York
ERB, EDMUND M., Manager, Merit Machine Mfg. Corp., New York
FLETCHER, HOWARD C., Chief Draftsman, Hull Div., Navy Yard, New York
GRIFFIN, GEORGE E., Mechanical Engineer, The Adder Machine Co., New York
GRUBER, MORRIS M., President and Engineer, Presto Machine Works, Brooklyn
HEIDELBAUGH, WILLIAM W., Secretary and Treasurer, Acme Cement Corp., Catskill
HOUGH, FREDERICK L., JR., Asst. Engineer, Edison Elec. Ill. Co., Brooklyn
McWILLIAMS, CLOYD C., Engineer of Machinery, American Loco. Co., Schenectady
MARSHALL, WALTER E., Buffalo Mgr., The Warner & Swasey Co., Buffalo
O'REILLY, PHILIP J., U. S. Inspector of Boilers, Steamboat Inspection Service, Custom House, New York
ROBLIN, WILMOT H., Inspector of Ordnance, U. S. Ord. Dept., Watervliet Arsenal, Watervliet

THOMAS, WILLIAM P., Chief Engineer, H. G. Vogel Co., New York
THOMPSON, CHARLES J., in charge Trench Warfare Section, Ord. Dept., New York
WHINERY, SAMUEL B., Sales Agent, Consulting Engineer, New York
WIBERG, HERBERT G., Chief Inspector, Compensation Inspection Ration Board, New York
WIDMER, JULES A., Designer, Confidential Experimental and Research Work, Sperry Gyroscope Co., Brooklyn

Ohio

BALBACH, EDWARD, Mechanical Engineer, James Leffel & Co., Springfield
BEAUMONT, JAY C., Chief Planner, Engrg Dept., B. R. Goodrich Co., Akron
GREENE, OSCAR V., General Manager, The Cleveland Stoker & Mfg. Co., Cleveland
LOCKHART, JAMES, Chief Engineer, The Lakewood Engineering Co., Cleveland
WEAVER, ROBERT R., Chief Engineer, Ralston Steel Car Co., East Columbus

Oregon

GILL, JOSEPH W., Associate Engineer and Chief Draftsman, Smith & Watson Iron Wks., Portland

Pennsylvania

BENZON, GEORGE H., JR., Chief Draftsman, William Sellers & Co., Inc., Jenkintown
BRODHEAD, ELBER H., Vice-Pres., Parkesburg Iron Co., Parkesburg
ECHOFF, WALTER H., Assistant General Master Mechanic, Midvale Steel & Ordnance Co., Coatesville
FUNK, NEVIN E., Operating Engineer, Philadelphia Elec. Co., Philadelphia
GILLETT, MERRIMAN C., Branch Manager, Spencer Heater Co., Philadelphia
HUMPTON, JOHN R., General Superintendent of Skelp Mill, Parkesburg Iron Co., Parkesburg
KEAL, GEORGE L., Resident Engineer, U. S. Shipping Board, Hog Island, Philadelphia
LOWELL, DWIGHT E., Assistant Machinery Fabrication Engineer, American International Shipbuilding Corp., Hog Island
MORRISON, LACEY H., Production Officer, Instrument Dept., Frankford Arsenal, Philadelphia
PORTER, ROY H., Asst. Mechanical Engineer, New Jersey Zinc Co., Palmerton
WILSON, BENJAMIN W., Designer and Superintendent of Constr. of Mech. Equipment, Ballinger & Perrot, New York and Philadelphia

Rhode Island

ANDERSON, ALEXANDER W., Inspector of Boilers, Fidelity & Casualty Co., of N. Y., Providence

Tennessee

FRYANT, HARRIS T., Specialty Salesman, Crane Co., Memphis
WORDEN, ARTHUR F., Fire Protection Engineer, Dupont Engineering Co., Jacksonville

Texas

PALMER, WILLIAM R., Mechanical Engineer, Cananea Consolidated Copper Co., El Paso

Utah

REDWINE, LEWIS S., Chief Draftsman, American Smelting & Refining Co., Garfield

Virginia

WILLARD, JAMES A., Chief Draftsman, Du Pont de Nemours Co., City Point

Washington

WATTS, ROBERT L., Mechanical Superintendent, St. Paul & Tacoma Lumber Co., Tacoma

Wisconsin

DE VLIEG, RAY A., Chief Engineer, Kearney & Trecker Co., Milwaukee
HYLAND, PATRICK H., Assistant Professor of Mech. Engrg., University of Wisconsin, Madison
KNIGHT, CLARK M., Inspector, United States Indian Service, Ashland

FOREIGN

Australia

LEWIS, EDWARD P., Designing and Construction Engineer, Partner Kelly & Lewis, Melbourne
RIGBY, EDWARD J., Consulting Engineer, Private Practice and for Northern Territory Federal Government, Melbourne

Canada

DICKSON, GEORGE H., Official Gauge Checker, U. S. Army Ord. Corps, Civilian Dominion, Arsenal, Quebec
GILES, GEORGE, General Manager, Vancouver Engineering Works, Ltd., Vancouver
JANSEN, WALTER A., Operating Manager, Canadian Steel Foundries, Ltd., Montreal

Costa Rica

PICADO, RAMON M., City Engineer, Cartago City Council, Cartago

England

MARSHALL, WILLIAM J., Managing Director, Richard Garrett & Sons, Ltd., Engineers, Westminster

France

BANKS, SAMUEL J., Director, Works Manager, Berlut Automobile Works, Lyons

Hawaii

NELL, EDWARD J., Manager, H. S. Gray Co., Honolulu

Japan

SCHENCK, W. EGBERT, Treasurer and General Manager, The F. W. Horne Co., Tokyo

Porto Rico

STOREY, NORMAN C., Mechanical Superintendent, Aguine Sugar Co., Aguine

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

District of Columbia

HARTFORD, ERNEST, Office Manager, Committee on Education and Special Training, War Department, Washington

Massachusetts

LLEWELLYN, ERNEST R., Assistant Chief Draftsman, American Steel & Wire Co., Worcester

Michigan

DIX, HORACE P., Secretary and General Manager, Wilmarth & Morman Co., Grand Rapids

Ohio

DETWILER, HOMER H., General Manager, The Enterprise Co., Columbiana

New Jersey

JACKSON, LEONARD D., Consulting Ballistic and Mechanical Engineer, American Standard Metal Products Corp., Paulsboro

New York

BROWN, ARTHUR J., President and Treasurer, B. A. B. Model Mfg. Co., New York
MONAHAN, THOMAS G., Assistant to Chief Engineer, The Donner Steel Co., Inc., Buffalo

Oklahoma

EMMETT, CARL P., Superintendent, Bell Oil & Gas Co., Stone Bluff

Pennsylvania

EVANS, HERBERT H., District Sales Manager, Coatesville Boiler Wks., Philadelphia
STRICKLER, HARRY K., Asst. Chief Engineer, Erie Forge & Steel Co., Erie

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

California

SHIPLEY, JACK B., Marine Engineer, Moore Shipbuilding Co., Oakland

Connecticut

ROOT, FREDERICK J., Major O. R. C., Army Inspector of Ordnance and Acting Quartermaster, Marlin Rockwell Corp., New Haven

District of Columbia

KNIGHT, BERNARD O., Aeronautical Mechanical Engineer, Production Engr. Dept., Bureau of Aircraft Production, Washington
ROSS, ROBERT M., 1st Lieut., Ordnance Dept. N. A. Mechanical Engineer, U. S. Chemical Plant No. 4, Washington

Georgia

BROOKS, EUGENE A., Sales Engineer, The Babcock and Wilcox Co., Atlanta

Illinois

ACCOLA, EDWARD C., Methods Engineer, Western Electric Co., Chicago
HACH, CLARENCE A., Mechanical Engineer, Western Electric Co., Chicago
SCHEEL, CHARLES F., Department Head, Western Electric Co., Inc., Hawthorne
MANLEY, LLOYD M., Section Head, Western Electric Co., Chicago

Maryland

EVANS, BOYD V., 1st Lieut., Ordnance Department, U. S. A., Aberdeen Proving Ground

Massachusetts

SPENGLER, RALPH A., Captain, Watertown Arsenal, Watertown

Michigan

ALDRICH, HENRY E., JR., Chief Draftsman, The Wickes Boiler Co., Saginaw

Minnesota

ROTHENBERGER, JAMES H., Asst. Supt., Minneapolis Steel & Machinery Co., Minneapolis

New Jersey

HARBESON, JAMES P., JR., Plant Engineer, Camden Forge Co., Camden
HARDING, ARTHUR B., Construction Engineer, U. S. Cast Iron Pipe & Foundry Co., Burlington
LENNOX, WESTON, Leading Draftsman, Babcock & Wilcox Co., Bayonne

New York

ADAMSON, ALLAN A., Chief Draftsman, Boucher Cork & Machine Co., New York
BROWN, ANTHONY F., Vice-President & General Manager, B. A. B. Model Mfg. Co., New York
HARDY, CHARLES, General Manager, Blair Tool & Machine Wks., New York
NORRIS, DONALD G., Experimental Motor Div., Curtiss Aeroplane & Motor Corp., Buffalo
PIERCE, HAROLD F., Lieut., In charge mechanical development, Medical Research Laboratory, Field No. 1, Mineola, Long Island
WELLS, ALBERT W., Engineer, General Electric Co., Schenectady

Ohio

BENJAMIN, MERRIL G., Power Plant Engineer, Youngstown Sheet & Tube Co., Youngstown

Pennsylvania

BRYANT, ROBERT E., Captain, Ordnance R. C., Inspecting Artillery Ammunition, c/o Worthington Pump & Mach. Corp., Hazelton
ROTHERY, LUDWIG W., Erecting Engineer, Westinghouse Electric & Mfg. Co., Philadelphia
SOSS, HENRY, Captain Ordnance Dept., U. S. A., Worthington Pump Co., Hazelton

Virginia

KURTZ, WALTER W., Engineer U. S. N. R. F., Supply Dept., Navy Yard, Norfolk

Canada

YARROW, NORMAN A., General Manager, Yarrows, Ltd., Victoria, British Columbia

FOR CONSIDERATION AS JUNIOR

Alabama

SNYDER, CLIFFORD L., 2nd Lieut., U. A. R. C., Nitrate Div., Ord. Dept., U. S. A., U. S. Nitrate Plant No. 1, Sheffield

Connecticut

COOK, FRED L., 2nd Lieut., Ordnance Reserve Corps, Scovill Mfg. Co., Waterbury
FLYNN, JAMES J., Asst., Chief Inspector of Ordnance U. S. Government, Remington Arms Bridgeport Wks., Bridgeport
HEALY, WILLIAM J., Laboratory Asst. in Mechanical Engineering, Sheffield Scientific School, Mason Laboratory of Mechanical Engineering, New Haven

District of Columbia

APPEL, SAUL C., Aeronautical Mechanical Engineer, Dept. of Military Aeronautics Supply Section, Buildings Grounds Branch, Washington
SMITH, BENJAMIN A., Technical Engineer, Bureau of Standards, Aero. Instrument Section, Washington

Georgia

SAUNDERS, WILLIAM H., Student, Georgia School of Technology, Atlanta

Illinois

HOGG, JOHN W., Corn Products Refining Co., Argo
HUTCHISON, FRED P., Efficiency Engineer, Western Electric Co., Inc., Chicago

Indiana

SACKSTEDER, ABNER F., Tool Designer & Checker, Nordyke & Marmon Co., Aviation Division, Indianapolis

Maryland

CRAWFORD, JOHN D., Chief Engineer, Maryland Pressed Steel Co., Hagerstown
MACOMBER, HENRY E., Technical Engineer at Power Plant No. 1, Edgewood Arsenal, Edgewood

Michigan

GUSTAVUS, CHARLES W., Engineer, Murphy Iron Works, Detroit
MERRITT, LEON F., Sr. Inspector of Airplanes & Airplane Engines, Aircraft Production Bureau, Detroit
SWENSON, CLARENCE Q., Asst. Engineer of Test, Ordnance Dept., U. S. A., Reo Motor Car Co., Lansing

New Jersey

MARSH, JOHN W., Designing Engineer, Calco Chemical Co., Bound Brook

New York

CUSTER, GARRY D., Lieut. Junior Grade, United States Navy, U. S. S. Montana, New York
FOSTER, JAMES F., Jr., Testing Materials, Curtiss Aeroplane & Motors Corp., Buffalo
HERRMANN, JOHN F., Mechanical Engineer, Herrmann & Grace Co., Brooklyn
JONES, WALTER H., 2nd Lieut. Ord. R. C., New York Air Brake Co., Watertown
NORMILE, THOMAS H. J., Ship Draftsman, Hull Division, Navy Dept., Brooklyn

Ohio

LINTON, DONALD S., Schedule Clerk, Ordnance Dept., Mosler Safe Co., Hamilton

Pennsylvania

BLACK, WILLIAM E., Shop Draftsman, Dravo Engineering Works, Neville Island

France

KERNS, ROY S., Assembling Locomotives, 19th Engineers (Railway) National U. S. Army, Co. A, American Expeditionary Forces

CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

New York

BLUMGARDT, ISAAC E., Plant Engineer, Bayles Ship Yards, Port Jefferson, L. I.

PROMOTION FROM ASSOCIATE-MEMBER

Georgia

GREGG, ROBERT, Secretary, Atlantic Steel Company, Atlanta

Illinois

SILLCOX, LEWIS K., Mechanical Engineer, Illinois Central Railway, Chicago

New Jersey

BRUNNER, HANS, Production Manager, Essex Production Co., Trenton

Massachusetts

BURGESS, A. BRADLEY, Vice President, Standard Plunger Elevator Co., Worcester

Michigan

HAYNES, EDWARD A., Second Vice-President, Pt. Huron Sul. & Paper Co., Port Huron

Texas

CRAWFORD, CHARLES C., Manager, A. M. Lockett & Co., Ltd., Houston

France

WOODS, SAMUEL H., Captain Q. M. C., U. S. A., Motor Transport Service, American Expeditionary Forces

PROMOTION FROM JUNIOR

California

BEATIE, CECIL E., Engineer, Shell Co. of California, San Francisco

Connecticut

BLACKMER, WALDO H., Works Service Manager, Electric Cable Co., Bridgeport

District of Columbia

SPICE, CHARLES G., Captain, Ord. R. C., Gun Division, Washington

Illinois

ROLLINS, L. E., Mechanical Engineer, Swift & Co., U. S. Yards, Chicago

Massachusetts

New York

TEHLE, CHARLES J., Chief Draftsman, Marine Dept., Kerr Turbine Co., Wellsville

Ohio

SVENSEN, CARL L., Assistant Professor, Ohio State University, Columbus

Pennsylvania

MACLEAN, ARCHIBALD, JR., Purchasing Dept., Engineer, Westinghouse Elec. & Mfg. Co., Machine Works, E. Pittsburgh
SMITH, HOWARD W., Chief Engineer, Standard Engineering Co., Ellwood City

Texas

PALMER, GUERNSEY A., Manager and Resident Engineer, De La Vergne Engine Co., Houston

SUMMARY

New applications	198
Applications for change of grading:	
Promotion from Associate	1
Promotion from Associate-Member	7
Promotion from Junior	10
Total	216

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by September 15 in order to appear in the October issue.

CHANGES OF POSITION

A. F. Van Deinse, formerly connected with the Federal Light and Traction Company, New York, has become associated with the Columbus, Delaware and Marion Electric Company, Marion, Ohio, as general manager.

Edwin H. Seaman, until recently insurance engineer, American Lloyds, New York, has accepted the position of engineer with Johnson and Higgins, New York.

A. H. Chas. Dalley, formerly manager of the Chicago office of the American Engineering Company, of Philadelphia, Pa., has become affiliated with the Locomotive Superheater Company, Chicago, Ill., in the capacity of consulting engineer.

J. O. Persons has accepted the position of general manager of Bayles Shipyard, Port Jefferson, L. I., N. Y. He was until recently associated with the Remington Arms Company, Bridgeport, Conn., in the capacity of works engineer.

J. Carlton Ward, Jr., has become associated with the Pratt and Whitney Company, Hartford, Conn. He was formerly connected with the productive statistics division, Watervliet Arsenal, Watervliet, N. Y.

Robert N. Field has severed his connections with the United States Smelting, Refining and Mining Company, to take a position with the Western Sugar Refinery of San Francisco.

Frederick B. Garrahan, formerly with John Royle and Sons, Paterson, N. J., is now associated with the McGraw-Hill Publishing Company, New York.

James G. Russell, formerly instructor in mechanical engineering, Post Graduate Department, U. S. Naval Academy, Annapolis, Md., has accepted a position with Day and Zimmermann, Inc., Philadelphia, Pa.

James D. Taylor has resigned his position of chief engineer and superintendent of the Twenty-third Street branch of the Y. M. C. A., to assume the duties of chief engineer and assistant superintendent of the Metropolitan Museum of Art, New York.

Frank O. Hoagland, formerly affiliated with the Pratt and Whitney Company, of Hartford, Conn., has become associated with The Bilton Machine Tool Company, Bridgeport, Conn.

W. B. Moses has severed his connection with A. Marx and Son, New Orleans, La., to accept a position with the Engineering Sales Company, Inc., of the same city.

Sverre Petersen, until recently identified with the Lucey Manufacturing Corporation of Tennessee, Chattanooga, Tenn., in the capacity of chief engineer, has accepted the position of engineer with the Roxana Petroleum Company of Oklahoma, Tulsa, Okla.

Ernest B. Talkes has resigned his position as master mechanic of the Federal Furnace Plant, By-Product Coke Corporation, South Chicago, Ill., to accept a similar position with the Inland Steel Company at Indiana Harbor, Ind.

L. W. Helmreich has assumed the position of engineer, electricity, gas, heat and water department of the Public Service Commission of Missouri, Jefferson City, Mo. He was formerly head of the electrical department of the Ranken Mechanical School, St. Louis, Mo.

Alex. B. McKechnie has become affiliated with the G. M. Parks Company, Boston, Mass. He was formerly connected with the Merrill Process Company, of the same city, in the capacity of sales engineer.

Wallace C. Mills, until recently machine designer with Root and Van Dervoort Engineering Company, East Moline, Ill., has assumed similar duties with the Janesville Machine Company, Janesville, Wis.

George A. Hickerson has resigned his position as engineer with McKesson and Robbins, Inc., New York, to accept the position of mechanical appraiser with Ford, Bacon and Davis, New York.

C. J. Beust has entered the mechanical department, U. S. Nitrate Plant, Muscle Shoals, Sheffield, Ala. He was formerly connected with E. I. du Pont and Company, Wilmington, Del., in the capacity of engineering draftsman.

Frederick R. Banks has resigned his position as assistant equipment engineer of the Remington Arms Union Metallic Cartridge Company, Inc., Bridgeport, Conn., to take a position as chief engineer with the McNab and Harlin Manufacturing Company, Paterson, N. J.

Z. E. Sargisson has resigned his position as assistant works engineer for the Pan Motor Company, St. Cloud, Minn., to accept a position as an assistant maintenance engineer with the B. F. Goodrich Company, of Akron, Ohio.

George H. Waters, formerly president of George H. Waters Company, Mariner Harbor, N. Y., has assumed the duties of president of the Raritan Dry Dock Company, Perth Amboy, N. J.

George H. Sharpe has resigned as chief engineer and director of Westcott and Mapes, Inc., New Haven, Conn., to accept the position of deputy administrative engineer for the State of Connecticut, U. S. Fuel Administration, Hartford, Conn.

Robert Mawson, formerly associate editor of the *American Machinist* and recently connected with the firm of Mawson Brothers of Providence, R. I., has accepted the position of publicity manager with the Quigley Furnace Specialties Company, of New York.

James G. Rossman, until recently financial manager for William Hurd Hillyer, New York, is now manager of the banking department of Converse D. Marsh, New York.

ANNOUNCEMENTS

Herbert A. Burns has accepted a position with the New Home Sewing Machine Company, Orange, Mass., in the capacity of manager of the shell plant.

F. Rodney Pleasonton has become connected with the Savage Arms Corporation, as general works manager of its plants at Utica, Sharon and Philadelphia.

Lieut. Col. P. P. Walker, Engrs. U. S. A., is now stationed at Camp Cody and expects to leave shortly for France. Lieutenant Walker is Dean of the School of Engineering, University of Kansas, Prof. Geo. C. Shaad taking his place during his absence.

R. L. Rowley, formerly with the Fire Marshal's Branch of the U. S. Shipping Board, Oakland, Cal., is now engineer for the Pacific division, in charge of fire protection in the shipyards, under the jurisdiction of the Shipping Board.

Henry E. Longwell has assumed the position of chief engineer for the Pierce, Butler and Pierce Manufacturing Corporation, Eastwood, Onondaga Co., N. Y.

S. Carl Shipley, of Minneapolis Minn., has charge of the training of approximately 350 army men who will serve in the capacity of drivers of automobiles and trucks in war service.

John V. Martenis, assistant professor of mechanical engineering at the University of Minnesota, Minneapolis, has undertaken the training of 300 enlisted men in the Navy who are to serve as machinist mates.

Edward E. Gay, Jr., has accepted the position of hull fittings engineer with the American International Shipbuilding Corporation, Hog Island, Pa. Mr. Gay will, however, still maintain his consulting engineering office in Philadelphia, Pa.

Percy Brown has been promoted to the position of general superintendent of the record factories at Bridgeport, Conn., and Toronto, Canada, of the Columbia Graphophone Manufacturing Company.

By order of the County Court, Queens County, dated August 13, 1918, Frederick Stiftermeister's name has been changed to Frederick Alden Spencer.

APPOINTMENTS

Harry K. Fox has been appointed mechanical engineer of the Chicago, Milwaukee and St. Paul Railway Company, Milwaukee, Wis., with headquarters at Chicago, Ill. He was formerly connected with the company in the capacity of engineer of tests.

Everett W. Swartwout, formerly with the New York office of the Nordberg Manufacturing Company, has been appointed manager of the Philadelphia office, with the particular task of serving all the departments of the Emergency Fleet Corporation and various technical departments in Washington, as the company's shops are largely devoted to Government work.

Olin H. Landreth, professor of civil engineering, Union College, Schenectady, N. Y., has been appointed to the Ordnance Department as mechanical engineer in the Production Bureau, and is to be stationed at Washington. To enable him to accept this appointment, the trustees of Union College have extended his leave of absence for another year.

Harry Himmelbau has been appointed assistant to Joseph Harrington, the administrative engineer, U. S. Fuel Administration for Illinois.

Charles C. Trump, secretary and mechanical engineer of the Humphrey Gas Pump Company, Syracuse, N. Y., has accepted an appointment as assistant administrative engineer, under the Federal Fuel Administration for New York State and the Bureau of Conservation of the United States Fuel Administration, devoting his entire time to the work of fuel conservation in the State of New York.

Edward N. Trump is acting as administrative engineer under the Federal Fuel Conservation for New York State, with office in Syracuse, N. Y. Mr. Trump is serving as a volunteer, giving half of his time to this work.

William G. Eager, formerly vice-president of the Valdesta Lighting Company and consulting engineer for the General Utilities and Operating Company of Baltimore, Md., received his commission as lieutenant of the line (senior grade) United States Naval Reserve Force, and has been assigned to Philadelphia field work in that district.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

CONSTRUCTION MEN on coke-oven plants. Men competent to follow out plans and details of construction and plant layout. Experience in chemical and gas plants serviceable. 0525.

ENGINEERS with experience in machine shops, and men of general engineering experience needed. 0549.

HIGH GRADE TECHNICALLY TRAINED MEN, preferably graduates of a mechanical or electrical engineering course. Those with some practical experience in testing or designing machinery preferred. 0552.

COMBUSTION ENGINEER wanted by the Bureau of Oil Conservation, Oil Division, U. S. Fuel Administration, for each of the following districts, to act as inspector, visiting all plants within his district using fuel oil and natural gas: Boston, Providence, New York City, Philadelphia, Pittsburgh, Buffalo, Detroit, Chicago, Minneapolis, Tulsa, New Orleans, and San Francisco.

It is desirable to have these men act as volunteers where possible, but the Administration is prepared to pay a reasonable compensation for men who cannot afford to give their services to the Government. Only men who have had experience in fuel-oil and natural gas combustion would be of value. 0568.

MECHANICAL, Civil, Electrical and Marine Engineers are required for shipyards, principally on Atlantic Coast. Work to be the designing and construction of hulls and ship equipment. 0597.

YOUNG MEN wanted for the Department of Military Aeronautics. Should have mechanical training, and if possible, be thoroughly grounded in electrical work. May be of draft age and will go as enlisted men, then assigned to Training School for Radio Mechanics and after instruction will be sent overseas. They will be inducted at once. Schools conducted in Pittsburgh and New York City.

CIVILIAN POSITIONS

SUPERINTENDENT for projectile shop. Must be able to handle men intelligently, have had actual experience in the forging and machining of shells, be thoroughly experienced in production work, and possess executive ability. Location Connecticut. 1-0523.

YOUNG SALES ENGINEER for leading firm of power-plant specialty manufacturers. Man with experience in power-plant equipment wanted; technical graduate preferred. Excellent prospects. Location Philadelphia. 1-0524.

ESTIMATOR DRAFTSMAN, who can read blueprints, do the necessary laying out and pick off quantities. Work is all in sheet and plate steel, tanks and boilers, and special apparatus. Location Jersey City. 1-0526.

YOUNG ENGINEER (draft exempt) to assist in supervising operation of private power plants and in engineering new industrial plants. Salary according to results. Location New York. 1-0528.

TWO COLLEGE GRADUATES for drafting room with a few years experience in detailing and drafting in connection with the layout of furnace work, elevator and conveyor machinery, boiler-plant work, etc. Men required to make stress diagrams and estimates of the various structures which they design, and take off quantity estimates. 1-0531.

DRAFTSMAN, experienced and competent man to take care of general layouts such as are made in case a new proposition has to be lined up in the drafting room for estimating purposes or for the purpose of general arrangement and best utilization of available ground area. Man wanted who is well acquainted with the handling of material in large quantities by mechanical appliances and who has preferably had experience in the same line of work at metallurgical plants. 1-0532.

EXPERIENCED CHECKER who can check up all drawings before they leave the drafting room as regards detail dimensions, and also go over the stress diagrams and the general design of buildings and various structures so that the checking will be complete and not have reference only to detail dimensions. 1-0533.

EDITOR with special knowledge in marine engineering and boiler manufacture. Headquarters New York. 1-0534.

ASSISTANT MASTER MECHANIC or MECHANICAL ENGINEER. Mechanical graduate or man with at least three years' college education and some practical experience in machine-shop work or factory maintenance. Work consists principally in the maintenance and operation of hydraulic pumps, presses, and similar lines. To start in office as a clerk and cost accountant at $100 per month. Progress and promotion will depend entirely upon the man himself. Location Canada. 1-0536.

ORGANIZING ENGINEER for large plants operating 30,000 to 40,000 hp. of boilers, large electrical units, also refrigeration machinery, evaporators, stills, gas machinery, and varied mechanical equipment. Young man who has had technical training and experience and is qualified to guide in mechanical development. Location Ohio. Salary depends on man. 1-0542.

DESIGNER for semi-Diesel or hot-bulb heavy-oil engines to be used for marine and land purposes; one who has had experience on this type of machinery. State requirements, salary, etc. Location New York. 1-0543.

MECHANICAL, CIVIL or AERONAUTICAL ENGINEER capable of handling mathematical work connected with the design of aeroplanes. Men with mathematical experience in other lines will be considered. Position is with aircraft factory on Long Island. 1-0556.

ASSISTANT TO DIRECTOR of large university engineering-experiment station, to have some teaching requirements; duties to include all editorial work connected with publication and distribution of bulletins, requiring some practical editorial experience. Initiative and ability to carry out work with minimum supervision on the part of head of the department. Salary will depend largely upon age, experience, and training of man. 1-0558.

YOUNG ENGINEER with some experience in assembling small parts such as time and percussion fuses will be afforded excellent opportunity to show worth as the head of fuse department of a large ammunition company. Salary commensurate with experience and demonstrated ability. Location Connecticut. 1-0562.

SUPERINTENDING MECHANICAL ENGINEER AND FOREMAN for tin-smelting plant. Men familiar with tin-ore products and remanufacturing. Location Brooklyn. 1-0563.

SUPERINTENDENT OF CONSTRUCTION for plant manufacturing conveying machinery. Desire executive type of man both from office and shop standpoint. Salary depends on man. Location New York. 1-0564.

FACTORY SUPERINTENDENT. Manufacturer of steel tanks desires to communicate with technical graduate, married man or one with dependents, who has had shop experience, knows up-to-date production methods, labor problems, and familiar with general cost accounting. In reply state experience and education. Salary to start $3000. Location Massachusetts. 1-0566.

COMBUSTION ENGINEER to do commercial engineering work. Experience with mechanical stokers. Good position for one desiring to prepare for sales work. Location Pittsburgh, Pa. 1-0567.

ENGINEERING SOCIETY requires man of judgment, experience, executive ability and personality, to develop standardization work. Position involves coördinating work of several important committees of manufacturers and users in mechanical engineering lines. State full qualifications and salary. 1-0569.

MECHANICAL ENGINEER along general lines of factory reorganization, together with some mechanical drafting. Salary to start $2500. Location Connecticut. 1-0571.

SALES ENGINEER, between 25 and 32, draft-exempt or in class 4. Must be energetic, have initiative and be a thinker. Man wanted with engineering-college degree and one year's shop experience on machine design, or high-school education and two or three years' work on machine design. Salary $1800, with excellent opportunity for advancement. To travel; New York headquarters. 1-0572.

DRAFTSMAN, preferably one with experience in hydraulic-turbine work. Permanent position and good opportunity for high-grade man only. Give full particulars in first letter. Location Ohio. 1-0573.

HEAD OF SCHOOL FOR BOYS in Detroit. Man experienced in the charge of boys' school covering the grades in the grammar and high-school. Chief requisite, personality. Salary $1500. 1-0574.

DRAFTSMAN on plant layout work of factory buildings. Concern engaged in the manufacture of steel barrels, tanks, oil pumps and portable furnaces for hardening and tempering steel. Location Massachusetts. 1-0575.

SUPERINTENDENT for factory employing about 200 men. Established business. Good opening for right man. Must be thoroughly experienced in general manufacturing, estimating and in the handling of men. Location New Jersey. 1-0576.

YOUNG MAN with some experience in drawing for preparation of wiring diagrams for motor-controller circuits. $15 to $25 per week, according to ability. Employment continuous until drafted into Government service, or, if exempt, can offer permanent position. Location New York. 1-0578.

SUPERINTENDENT for Barrel Manufacturing Division. Must be familiar with making of barrels of light-gage steel; girths are seam welded and heads are lock seamed; experience on oxy-acetylene is also essential.

Splendid opportunity for high-class man. Location Massachusetts. 1-0579.

CHEMISTS OR ENGINEERS wanted by firm engaged in coal-tar distillation and roofing manufacture. Work will be of an experimental nature in connection with new processes of manufacture and new use for products. Location New York. 1-0580.

CHIEF DRAFTSMAN AND GENERAL ASSISTANT to chief engineer. Progressive paper and pulp manufacture. Concern in Canada offers excellent opportunity to capable man preferably with paper-mill experience. 1-0581.

TECHNICAL TRAINED YOUNG MAN with several years practical work wanted for position in publicity department of large manufacturer doing world business. Should be in Class 4 draft. Splendid opportunity for capable man in sales work. Advertising experience not necessary. Location Ohio. 1-0582.

ENGINEERING OR ARCHITECTURAL DRAFTSMAN capable of doing good work, at least high-school education. Work will be largely drafting in office of consulting engineer and includes acting as assistant to engineer on tests in power plants, etc. Some inspection of construction work. Salary $25 per week. Location New York. 1-0583.

ENGINEERS capable of handling responsible position in newly-organized production department of Detroit automobile company, engaged on war orders. Salary $40 to $50 per week. 1-0584.

INSTRUCTOR in mechanical drawing and machine design for day technical school and evening classes. Salary $2000. 1-0585.

TECHNICAL GRADUATE of about 28 years of age, with some experience in installing office and shop systems; physically unfit for military service, or placed in limited service. Man with initiative and ability to get results is preferred, even if no previous experience in the work above named. Location Massachusetts. 1-0586.

TWO MANAGERS manufacturing department and procurement of equipment for expanding cartridge department Illinois. Position of works manager covers manufacturing of cartridges in general way. Can use a factory manager with ability in manufacturing complicated and technical line of goods. 1-0587.

EFFICIENCY ENGINEER. Experienced man with technical training for testing and efficiency work in steam-electric plant near New York. Man with initiative who can recommend and carry out improvements. Tact requisite. State age, education, experience, references and salary expected. 1-0588.

ASSISTANT EFFICIENCY ENGINEER. Young technical man with one or two years' power-plant experience as assistant to efficiency engineer. Opportunity for broad experience and advancement; location near New York. State age, education, experience, references and salary expected. 1-0589.

WORKS MANAGER for plant located in Southern Ohio, manufacturing line of pumps, compressors, heaters, cotton-seed material, machinery and the like. The plant comprises foundry, pattern shop, machine shop, etc. At present is engaged in the assembling of six-ton tractors. Man capable of earning from $6000 to $8000 per year to start. Should be familiar with modern duplicate-parts manufacture, modern shop and foundry administration, cost accounting, stores keeping and kindred allied subjects; capable of developing into general manager. 1-0590.

BUYER of fabricated parts for aviation motors. Work would be under control of outside manufacturing department: qualifications extraordinary, and differ decidedly from those required of the ordinary buyer or purchasing agent. Man with considerable buying experience on fabricated parts, with concern which has been assembling automobiles from purchased parts, or similar buying experience along gas-engine lines. Shop experience and familiarity with machine tools. Proposition concerns one of furnishing tools and materials to the vendor, specifying just how the parts are to be made. American citizen, 35 to 45 years old, capable of earning from $4500 per year up. Position must be filled immediately. Location New York. 1-0591.

PLANNING DEPARTMENT POSITION consists of laying out the work for the different departments and following it all through the different departments to see that it is pushed through the factory in shortest possible time. Working on 92% to 96% Government Work. Location Philadelphia. 1-0592.

MEN WITH TECHNICAL TRAINING IN MECHANICAL ENGINEERING wanted by manufacturer of recording meters and power plant equipment; opening for several men in engineering department. Some power-plant experience. Position offers good inducements, experience and future often leading to permanent positions in efficiency work in large power plants. 1-0593.

SUPERINTENDENT, mechanical installation, familiar with plumbing, heating and lighting, electric line work and house wiring. Salary $3600 to $5000. 1-0599.

YOUNG MEN available for department of mechanical engineering of large Middle West University to replace men called into Government service. 1-600.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be on hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MECHANICAL ENGINEER, age 35, thirteen years' experience, covering design, construction and maintenance of industrial works. Capable of acting as assistant chief engineer, master mechanic or superintendent of steel rolling mill on any maintenance proposition. Thoroughly conversant with technical and practical side of steam, pneumatic and hydraulic work. Also familiar with electrical apparatus. Prefers location near New York, Philadelphia or Baltimore. 1-222.

EXECUTIVE, member, 49, practical workman, technical education, wide experience in manufacturing, covering shop, sales, design, office, finance, management. Large experience in the forging business. 1-223.

GENERAL OR WORKS MANAGER, American, age 47, practical mechanic and designer; executive and sales experience; designed and placed on market well-known line automatic machinery. Successful in handling skilled labor. Working knowledge of general and cost accounting systems, etc. At liberty about September 1st. Position in which an interest in business could be obtained preferred. Salary $5000. 1-224.

MEMBER with broad business and engineering experience here and abroad. American, 45; fully conversant with the principal languages; knowledge of purchasing and selling; tactful in handling of men; at present employed as designer of special plant. Desires change preferably to supervise work, inspect or represent, or act as assistant to executive where responsibility is required. To start, $4000. 1-225.

COMPETENT FOUNDRY MAN capable of handling any foundry proposition, having charge of some of the largest and most up-to-date foundries in the country. 1-226.

MANAGER, EXECUTIVE ORGANIZER. Chemical engineer, technical graduate, not subject to draft. Twenty years' experience conduct of large industries. Fine record in designing and construction. Ample reference. 1-227.

MECHANICAL AND REFRIGERATING ENGINEER, member, thoroughly experienced in refrigerating and general engineering and design of all kinds of machinery power plants, refrigerating and ice-making plants; competent to take charge of office force, supervise erection and handle tactfully executives and men; exemplary habits. 1-228.

MECHANICAL ENGINEER, member, technical graduate, 38; long experience in heavy, light and multiple manufacture, experimental and development work. At present chief draftsman on elevating and conveying machinery. Relations with subordinates and co-workers invariably pleasant and successful. Desires new permanent position in engineering executive line, with increased scope and responsibilities. 1-229.

MECHANICAL ENGINEER, associate member, age 32, married. Now employed as mechanical engineer of plant making large number of interchangeable brass and light gray iron parts. Eleven years tool designing, testing and general engineering and manufacturing. Desires location in Southern New England. 1-230.

CHIEF OPERATING ENGINEER, associate, 40 years of age, with 15 years' experience, desires situation with progressive concern. Nine years' satisfactory service as chief engineer. Experience covers steam, electric and producer gas; Diesel engines and refrigeration. 1-231.

WORKS MANAGER, broad practical experience in design and interchangeable quantity production of small high grade apparatus, such as registers, adding, coin-counting machines and fuses. Can organize new plants intending to engage in above lines. Have been successful in the handling and training of help and securing maximum results from equipment. Fully acquainted with factory systems. Employed at present. Only high-grade connection will be considered. 1-232.

MANAGER now successfully conducting Philadelphia office for large concern manufacturing electrical, mechanical and pneumatic equipment desirous of making change; has acquired unusual business and technical training during 8 years of continuous service with present company. Thoroughly experienced in sales, engineering and construction; handling these departments now in territory comprising five Middle Atlantic States. Young man, married, with excellent references. Salary approximately $4500. 1-233.

PURCHASING EXECUTIVE, also qualified as supervisory-office and plant engineer. Acquainted with largest manufacturers of mechanical and electrical equipment and suppliers of engineering materials. At present engaged along these lines, wishes connection with opportunity for greater activity. 1-234.

SALES ENGINEER, mechanical-electrical, technically trained; American, 35 years of age, married; speaks Spanish and Portuguese, acquainted with machine tools, construction machinery, mechanical-electrical equipment, sugar machinery, 13 years' sales experience; executive ability, desires to connect with manufacturer as sales engineer for South America. 1-235.

SALES ENGINEER with Latin-American experience, speaking Spanish, wishes to make connection for representation in Latin-American countries or Spain. Special qualifications for successful representation in railway supplies, power-plant equipment, etc. Thoroughly versed in foreign trade methods. Mechanical engineer, fourth class in draft. 1-236.

EXECUTIVE, experienced buyer and publicity man; M. E. graduate, located in New York City, will execute commissions for out-of-town concerns, and can devote portion of each day to outside interests. Address care of The Journal. 1-237.

[illegible] Blue print [illegible] de [illegible] No. 3, L. W. F. Tractor Biplane; No. 5, L. V. G. Tractor Biplane; No. 6, Wright Light Scout; No. 7, London and Provincial Tractor; No. 8, Aeromarine Hydroplane; No. 9, Standard Twin Motor Biplane; No. 10, United Eastern Tractor Biplane; No. 11, Lawson Tractor Biplane; No. 12, Friedrichshafen Biplane; No. 23, Curtiss 3-wheel exhibition pusher biplane; No. 30, Nieuport Scout. *New York, 1916-18.* Purchase.

AMERICAN WIRE ROPE. Catalogue and Handbook. *1913.* Gift of American Steel & Wire Company.

AN APPRECIATION OF TWO GREAT WORKERS IN HYDRAULICS. Giovanni Battista Venturi, born 1746; Clemens Herschel, born 1842. By Walter G. Kent. *London, 1912.* Gift of Clemens Herschel.

L'ARMÉE ALLEMANDE A LOUVAIN EN AOUT 1914 ET LE LIVRE BLANC ALLEMAND DU 10 MAI 1915. DEUX MÉMOIRES. *Port Villez, 1917.* Gift of Prof. O. Steels.

THE ATHENAEUM. Subject Index to Periodicals. 1916. Science and Technology, including Hygiene and Sport. *London, 1918.* Purchase.

LA BELGIQUE ET L'ALLEMAGNE. Textes et documents précédés d'un avertissement au lecteur par Henri Davignon. *n. p., 1915.* Gift of Prof. O. Steels.

BIG CREEK INITIAL DEVELOPMENT, PACIFIC LIGHT AND POWER CORPORATION. *1914.*

BOILER FURNACE OPERATION. Science and Common Sense. By Lester Budd. *Philadelphia, n. d.*

CANADA. Munition Resources Commission. Report of the work of the Commission, Nov. 1915-Feb. 1918. First. *Ottawa, 1918.* Gift of Commission.

CLEARING LAND OF ROCKS FOR AGRICULTURAL AND OTHER PURPOSES. By J. R. Mattern. *New York, 1918.* Gift of Institute of Makers of Explosives.

CLEARING LAND OF STUMPS. *New York, 1917.* Gift of Institute of Makers of Explosives.

COLORADO SCIENTIFIC SOCIETY. Year Book. 1882-1916. *Denver, 1916.* Gift of Society.

COMMERCIAL CREDITS THROUGH ACCEPTANCE. Address by Albert Breton. *New York, 1918.* Gift of Guaranty Trust Company.

CONCRETE CONSTRUCTION. June 1918, prepared by Portland Cement Association. Gift of Association.

COURS DE MÉCANIQUE. vols. 1-4. By L. Guillot. *Paris, 1911, 1913, 1918.* Purchase.

DIGEST OF THE FEDERAL RESERVE ACT, including amendments to June 21, 1917. *New York, 1917.* Gift of Guaranty Trust Company.

DISEASE IN MILK. The remedy Pasteurization. The life work of Nathan Straus. Ed. 2. *New York, 1917.* Gift of Mrs. Lina Gutherz Straus.

ELECTRICAL WIRES AND CABLES. Catalogue and Handbook. *1910.* Gift of American Steel & Wire Company.

ELECTRIFICATION OF RAILROADS AS A WAR MEASURE. *East Pittsburgh, 1918.* Gift of Westinghouse Electric & Manufacturing Co.

ESSAYS OF CLEMENS HERSCHEL. Gift of Clemens Herschel.

EXTRACTING NITROGEN FROM THE ATMOSPHERE AT A POWER COST OF OVER 221 TONS PER DAY, FOR A 1000 KILOWATT POWER PLANT (equivalent to over 5,950,000 cu. ft. of Nitrogen gas), or 248 cu. ft. for one kilowat hour. Edition 5. By J. F. Place. *Glenridge, N. J., 1918.* Gift of author.

FEDERAL ESTATE TAX. LAW AND REGULATIONS. Act of Sept. 8, 1916, amended March 3, 1917. *New York, 1917.* Gift of Guaranty Trust Company.

INDUSTRIAL HEATING AS A CENTRAL STATION LOAD. Parts 1-2. *New York, 1917.* Gift of D. D. Miller.

MOODY'S MANUAL OF RAILROADS, 1918—Public Utilities Section. *New York, 1918.* Purchase.

——Complete list of securities maturing July 1, 1918, to June 30, 1920. Vol. VI. *New York, n. d.* Gift of Moody Manual Co.

NEW JERSEY. Department of Conservation and Development. Annual Report, 1917. *Union Hill, N. J., 1918.* Gift of Department.

NEW SOUTH WALES. Water Conservation and Irrigation Commission. Report, 1917. *Sydney, 1918.* Gift of Commission.

NEW YORK CITY. Board of Water Supply. Contract drawings for the construction of portions of the Peekskill division of the Catskill Aqueduct between Hunter's Brook and Foundry Brook Valleys. (Contract No. 2.)

——Contract drawings for the construction of a portion of the Esopus Division of the Catskill Aqueduct in the towns of Olive and Marbletown, Ulster Co., N. Y., 1908. (Contract No. 11.)

——Contract drawings for the construction of Hunter's Brook and Scribner Tunnels and portions of Yorktown cut and cover in the Croton Division of the Catskill Aqueduct in the town of Yorktown, Westchester Co., N. Y., 1908. (Contract No. 23, with specifications.)

THE PROMISE OF OUR VISION. Address by Francis H. Sisson. *New York, 1918.* Gift of Guaranty Trust Company of New York.

PUBLIC UTILITIES REPORTS ANNOTATED. 1918-A. *Rochester, 1918.* Purchase.

——Professional reference list. 1918 issue. *Rochester, 1918.* Purchase.

A RECORD THAT IS A PROMISE. An account of the changes wrought by the war in the financial and industrial structure of Canada. *New York, 1918.* Gift of Guaranty Trust Company of New York.

RED CROSS INSTITUTE FOR CRIPPLES AND DISABLED MEN. Placement Technique in the employment work of the Institute. By Gertrude R. Stein. (Publications, Series 1, no. 9.)

——Relation of the short, intensive industrial survey to the problem of soldier re-education. By G. A. Boate. (Publications, Series 1, no. 10.)

——Training in English Technical Schools for disabled soldiers. By John C. Faries. (Publications, Series 1, no. 8.)

——Vocational School for disabled soldiers at Rouen, France. By J. Breuil. (Publications, Series 1, no. 11.)

SAFE-GUARDING THE HOME AGAINST FIRE. A fire prevention manual for the school children of America. Prepared for the United States Bureau of Education by the National Board of Fire Underwriters.

A SHADE TREE GUIDE. By Alfred Gaskill. *Union Hill, N. J., 1918.* Gift of New Jersey. Department of Conservation and Development.

SPEEDING UP AMMUNITION AND MUNITION PRODUCTION. "Gravity."

STATISTICAL ABSTRACT OF THE UNITED STATES. 1917. *Washington, 1918.* Gift of U. S. Department of Commerce. Bureau of Foreign and Domestic Commerce.

STATISTICS OF EXPRESS COMPANIES. Annual Report. 7th. *Washington, 1918.* Gift of Interstate Commerce Commission.

TEACHING OF SAFETY IN TECHNICAL SCHOOLS AND UNIVERSITIES. A memorandum prepared for the aid of those desiring to undertake such work. National Safety Council, June, 1918. Gift of National Workmen's Compensation Service Bureau.

USE OF EXPLOSIVES IN MAKING DITCHES. *New York, 1917.* Gift of Institute of Makers of Explosives.

USE OF EXPLOSIVES IN THE TILLAGE OF TREES. *New York, 1918.* Gift of Institute of Makers of Explosives.

TRADE CATALOGUES

AERO PULVERIZER COMPANY. New York, N. Y.

Circular No. 57. Shain copper terminals.

STURTEVANT, B. F., COMPANY. Hyde Park, Mass.
Catalogue No. 150. Fuel economizers and air heaters.
—— No. 234. Steel-plate blowers and exhausters.

L. SONNEBORN SONS, INC.
Lapidolith for all concrete floors. Descriptive booklet.

WHEELER CONDENSER & ENGINEERING CO. Carteret, N. J.
Bulletin No. 109-B. Wheeler-Balcke Cooling towers. 1918.
Bulletin describing The Lillie Evaporator for Waste Waters.

SELECTED TITLES OF ENGINEERING ARTICLES

THE section Selected Titles of Engineering Articles appears in this issue on an enlarged scale.

This development is essentially a war activity. As a result of the war, engineers are constantly confronted with new problems and in consequence of the reconstruction period to follow, this condition will undoubtedly continue to exist for a long time to come.

One of the greatest services which the Society can render at this critical period is to place at the disposal of engineers, as a basis for their work, the means for using the wealth of data and general information published from month to month in the world's technical press. For this to be of any considerable value to the engineer, he must know, first, what information has appeared, and second, where it is to be found. To supply this knowledge in concise and convenient form is the purpose of the Selected Titles as now published.

This work has been made possible by the remarkable collection of current periodicals available in the Library of the United Engineering Society, which is by far the greatest in this country and probably in any country. The Library receives, even now, when some of the foreign periodicals have ceased to come to its shelves, close to a thousand different papers, magazines and transactions of societies in the engineering and scientific fields, in not less than ten languages. The Society's engineering staff examines these publications as they are received and prepares the cards ultimately used for the Selected Titles Section in THE JOURNAL.

In the preparation of the Selected Titles Section chief attention is paid to articles directly concerned with the branches of mechanical engineering. When it is thought they will be of interest or value to mechanical engineers, however, other articles are listed, in the realms of physics and chemistry; civil, mining and electrical engineering, technology, etc.; and in subjects in broadly related fields such as training and education, safety engineering, fire protection, employment of labor, welfare work, housing, cost keeping, patent law, public relations, etc.

The system of classification used is that which it is believed has come to be generally regarded as the best, namely, the simple alphabetical arrangement with the articles under heads and sub-heads which are varied from month to month according to the subject-matter to be indexed. Cross-references have been introduced and it is particularly to be noted that where the titles themselves are not sufficiently descriptive, explanatory sentences have been appended. This feature much more than doubles the labor and expense and, we are assured, correspondingly enhances the value of the index to the reader.

PHOTOSTATIC PRINTS

Photostatic copies may be obtained of any of the articles listed in this section.

Price for each print (up to 11 x 14 in. in size), 25 cents, plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Orders should be sent to

HARRISON W. CRAVER, *Director,*
Engineering Societies Library,
29 West Thirty-ninth Street,
New York.

AERONAUTICS

Aeroplane Design

Directional Stability of an Airplane. Frederick Bedell. Sibley Jl. of Eng., vol. 32, no. 11, August 1918, pp. 166-167. Exposition of the mechanics of directional stability of an airplane.

Balloons

Military Aerostatics. H. K. Black. Aerial Age, vol. 7, no. 20, July 29, 1918, p. 957. Theory of ballooning. (To be continued.)

Engines

Aluminum Pistons for Aero-Engines. Engineer, vol. 126, no. 3262, July 12, 1918, p. 35, 2 figs. Description of the aluminum pistons found in the Benz engine of a captured German plane.

The Design of Aeroplane Engines. John Wallace. Aeronautics, vol. 15, no. 246, July 3, 1918, pp. 10-11, 2 figs. Details of design employed for the purpose of securing a smooth torque and approximate balance of the moving parts of aircraft engines. (Continuation of serial.)

General Problems

Present-Day Problems in Aeronautics. William B. Stout. Motor Travel, vol. 10, no. 2, July 1918, pp. 20-22. From an address delivered before the Society of Automotive Engineers.

Some Outstanding Problems in Aeronautics. W. F. Durand. Aeronautics, vol. 15, no. 246, July 3, 1918, pp. 19-26. Sixth Wilbur Wright Memorial lecture, read before the Aeronautical Society on June 25, 1918.

Individual Types

The A. E. G. Bombing Biplane. Engineer, vol. 125, no. 3258, June 7, 1918, pp. 484-487, 14 figs. Details of construction and performance of a reconstructed captured German biplane.

The Roland D. II Biplane (Biplan Roland D. II). L'Aérophile, year 26, nos. 9-10, May 15, 1918, pp. 129-132, 8 figs.

Instruments

Perfected Aircraft Compass (Compas Perfectionné de Direction, en Navigation Aérienne). H. Vincent. L'Aérophile, year 26, nos. 9-10, May 15, 1918, pp. 133-136, 6 figs. Describes a *multiplex* compass for use in aerial navigation.

To Ascertain the Speed and Direction of Aeroplanes Over the Water. Aerial Age, vol. 7, no. 19, July 22, 1918, pp. 914-915, 2 figs. Exposition of Admiral Fiske's proposed method.

Materials of Construction

Determination of the Permeability of Balloon Fabrics. Junius D. Edwards. Aviation, vol. 5, no. 1, August 1, 1918, pp. 30-33, 6 figs. (To be concluded.)

How Moisture Affects the Strength of Aircraft Fabrics. G. B. Haven. Automotive Industries, vol. 39, no. 3, July 18, 1918, pp. 100-108, 5 figs. Tests on cotton, linen, balloon fabric, tire fabric and cords.

Steel Tubes, Tube Manipulation and Tubular Structures for Aircraft. W. W. Hackett and A. G. Hackett. Automotive Eng., vol. 3, no. 6, July 1918, pp. 279-260. Review of method of manufacture of tubular work and of some of the forms of manipulation upon steel tubing. From a paper read before the Aeronautical Society, London, May 2. (To be continued.)

The Metallurgist and the Aircraft Program. H. F. Wood. Am. Drop Forger, vol. 4, no. 7, July 1918, pp. 281-282. Description of various parts in Liberty motor, showing how design and choice of material are controlled. (To be continued.)

Model Aeroplanes

Model Aeroplane Building as a Step to Aeronautical Engineering. John [illegible]. M[illegible]Mahon. Aerial Age, vol. 7, no. 20, July 29, 1918, p. 971, 18 figs. Principles of streamline study.

Propellers

A Résumé of Airscrew Theory. M. A. S. Riach. Aeronautics, vol. 15, no. 246, July 3, 1918, pp. 12-15. An attempt to coördinate the aerofoil and momentum theories of screw propulsion.

Conventional Propeller Calculations. F. W. Caldwell. Aviation, vol. 5, no. 1, August 1, 1918, pp. 21-26, 24 figs.

Notes on Airscrew Analysis. M. A. S. Riach. Aeronautics, vol. 15, no. 247, July 10, 1918, pp. 41-42, 4 figs. Proposed modifications in the theory outlined under the title, The Screw Propeller in Air, in Aeronautics of March 21. (Continued from issue of June 12, 1918.)

The Efficiency of an Airscrew. M. A. S. Riach. Aeronautics, vol. 15, no. 247, July 10, 1918, pp. 38-39. Study of the efficiency of an airscrew approached by a consideration of the efficiency of the various elements forming each blade.

Predicting Strength and Efficiency of Airplane Propellers. F. W. Caldwell. Automotive Industries, vol. 39, no. 3, July 18, 1918, 14 figs. Charts and formulæ for calculating horsepower absorbed and torque delivered at given engine and plane speeds.

The Characteristic Coefficients of a Propeller and Some Methods of Plotting Them. E. P. King. Aeronautics, vol. 15, no. 246, July 3, 1918, pp. 4-9, 6 figs. Study of some problems dealing with the variable-pitch propeller. (Continued from issues of Jan. 2, May 1 and June 19, 1918.)

See also Physics (Meteorology).

AIR MACHINERY

Air Compressors

Air Compressor Troubles. R. J. Bailey. Compressed Air Mag., vol. 23, no. 8, August 1918, pp. 8849-8850. Results obtained from a described arrangement.

Lubrication of Air Compressors. W. H. Callan. Coal Age, vol. 14, no. 5, August 1, 1918, pp. 211-213. Suggests that a fairly light oil might be as successful as a heavy oil.

Note.—The abbreviations used in indexing are as follows: And (&); American (Am.); Associated (Assoc.); Association (Assn.); Bulletin (Bul.); Bureau (Bur.); Canadian (Can.); Chemical or Chemistry (Chem.); Electrical or Electric (Elec.); Electrician (Elecn.); Engineer [s] (Engr. [s]); Engineering (Eng.); Gazette (Gaz.); General (Gen.); Heating (Heat.); Industrial (Indus.); Institute (Inst.); Institution (Instn.); International (Int.); Journal (Jl.); London (Lond.); Machinery (Machy.); Machinist (Mach.); Magazine (Mag.); Marine (Mar.); Mining (Min.); Municipal (Mun.); National (Nat.); New England (N. E.); New York (N. Y.); Record (Rec.); Refrigerating or Refrigeration (Refrig.); Review (Rev.); Railway (Ry.); Society (Soc.); United States (U. S.); Ventilating (Vent.); Western (West.); State names (Ill., Minn., etc.); Proceedings (Proc.); Transactions (Trans.); Supplement (Supp.); Mechanical (Mech.); Scientific (Sci.).

Blowing Engines

1500-HP Gas Blowing Engine. Engineer, vol. 126, no. 3262, July 5, 1918, p. 10, 2 figs. Description of large gas blowing engine built for the Partington Steel & Iron Co., Ltd.

Shell Plant

Compressed Air in a Shell Plant. R. E. C. Martin and S. B. King. Mine & Quarry, vol. 10, no. 4, July 1918, pp. 1051-1055. Illustrated article describing installation and operation of compressed air at the plant of Winslow Bros. Co., Chicago, Ill.

BRICK AND CLAY

Burning Clay Wares. Ellis Lovejoy. Clay Worker, vol. 70, no. 1, July 1918, pp. 32-82. Deals with updraft kilns. (Continuation of serial.)

How to Proceed to Cut Burning Costs. J. K. Moore. Brick and Clay Rec., vol. 53, no. 3, July 30, 1918, pp. 207-212, 4 figs. Suggestions to improve the system of burning in an average-size clay plant equipped with round down-draft kilns.

BRIDGES

Arched Steel Cantilevers Used in Park Avenue Viaduct. Harry W. Levy. Eng. News-Rec., vol. 81, no. 2, July 11, 1918, pp. 81-83, 5 figs. Details of viaduct at Grand Central Terminal, New York.

Foundations, Forms and Concrete Distribution Mark Bridge Construction. Edward W. Stearns. Eng. News-Rec., vol. 81, no. 2, July 11, 1918, pp. 68-72, 9 figs. Describes combination unit wood and steel forms and steel arch centers that were used many times.

BUILDING AND CONSTRUCTION

Concrete Houses

Edison House Idea Outdone. Concrete, vol. 13, no. 2, August 1918, pp. 42-46, 15 figs. Layout of 40-house group being built by Ingersoll system, near Elizabeth, N. J.

Interior Construction of the Concrete Industrial House. M. D. Morrill. Contract Rec. & Eng. Rev., vol. 32, no. 30, July 24, 1918, pp. 587-588. Review of the different interior constructions used and suggestions regarding their respective adaptability to various purposes.

Methods of Constructing Concrete Houses. K. H. Talbot. Contract Rec. & Eng. Rev., vol. 32, no. 30, July 24, 1918, pp. 581-584. Résumé of types of forms used in solving the house problem.

Report of American Concrete Institute Committee on Industrial Houses. Eng. & Cement World, vol. 13, no. 2, July 15, 1918, pp. 19-20.

Ten Fireproof Houses of Field and Precast Concrete. Concrete, vol. 13, no. 2, August 1918, pp. 69-71, 12 figs. Description of ten 6-room fireproof dwellings being completed at Ransford, Pa., for the Lehigh Coal & Navigation Co., by the Simpsoncraft system of construction.

Concrete Stairs

Concrete Stairs. A. M. Wolf. Concrete, vol. 13, no. 2, August 1918, pp. 58-60, 8 figs. Designs and design methods.

Earth Pressures

Earth Pressures. Leo Hudson. Can. Engr., vol. 35, no. 3, July 18, 1918, pp. 61-64. Summary of the theories on the subject. Abstract from Trans. Am. Soc. of Municipal Improvements.

Military Buildings

Semi-Military Buildings in the National Army Cantonments. Robert H. Moulton. Architectural Rec., vol. 44, no. 1, July 1918, pp. 21-30. Arrangement and interiors of camp buildings.

Pile Driving

World's Record for Pile Driving. Eng. & Contracting, vol. 50, no. 3, July 17, 1918, p. 58. 220 65-ft. piles put down by 11 men in 9 hr. 5 min.

Sandstone

Sawing and Working Sandstone. Stone, vol. 39, no. 7, July 1918, pp. 324-326. Considerations governing the design and construction of a finishing plant in the vicinity of a quarry.

Shipyards

Hog Island's Ship-Erection Equipment: Four Hundred Tower Derricks for Fifty Ways. Eng. News-Rec., vol. 81, no. 2, July 11, 1918, pp. 77-80, 7 figs. Description of prominent features and details.

How Ship and Housing Work Is Organized and Operated. Eng. News-Rec., vol. 81, no. 3, July 18, 1918, pp. 122-124.

Survey of Sites

Surveying for Housing Projects. Mun. Jl., vol. 45, no. 2, July 13, 1918, pp. 28-29. Instructions by Bureau of Industrial Housing and Transportation for making topographical survey and maps of sites for housing developments.

Wood Mill Buildings

Wood in the Construction of Mill Buildings. W. Kynoch and R. J. Blair. Can. Engr., vol. 35, no. 5, August 1, 1918, pp. 95-96, 2 figs. Corrosive sublimate suggested as preservative where conditions are favorable to growth of fungi.

CEMENT AND CONCRETE

Concrete-Making Plants

Cedar Hollow, Pa., Plant of Charles Warner Co. Concrete (Cement Mill Section), vol. 13, no. 2, August 1918, pp. 13-15, 9 figs. Rotary kiln for lime burning and method of handling the hydrating process.

Gravel Plant of Tarco Construction Co., Cincinnati. Concrete (Cement Mill Section), vol. 13, no. 2, August 1918, pp. 11-12, 2 figs. Arrangement and equipment of the plant.

Concrete Mixes

Effects of Grading of Sand and Consistency of Mix Upon the Strength of Concrete. Llewellyn N. Edwards. Can. Engr., vol. 35, no. 3, July 18, 1918, pp. 49-52, 9 figs. Supplement to the writer's reports of his tests published in the issues of Aug. 16, 23 and 30, and Sept. 6, 1917.

Effect of Time of Mixing on the Strength of Concrete. Duff A. Abrams. Can. Engr., vol. 35, nos. 4 and 5, July 25, 1918, pp. 73-78, 3 figs.; Series of tests on machine-mixed materials; August 1, pp. 103-115, 48 figs.; Tests, diagrams and tables of data obtained from experimental tests. Paper read before Am. Concrete Inst. (To be concluded.)

Method of Proportioning Concrete-Mixtures Based on the Surface-Areas of the Aggregates. L. N. Edwards. Western Eng., vol. 9, no. 8, August 1918, pp. 308-309, 5 figs. Series of experiments and theory advanced by writer that the proportion of cement in a given mortar or concrete mixture should depend upon the surface-area of the aggregates.

Slag as an Aggregate for Concrete Ships. Curtis C. Meyers. Iron Age, vol. 102, no. 3, July 18, 1918, pp. 152-154, 4 figs. Slag concrete claimed to be superior to crushed stone or pebble concretes.

The Basic Principle of Concrete Mixes and the Truly Fundamental Role Played by Water. Duff A. Abrams. Eng. & Contracting, vol. 50, no. 4, July 24, 1918, pp. 77-78. Experimental research concerning the effect of water on the strength and other properties of concrete.

The Basic Principle of Concrete Mixes. Duff A. Abrams. Min. & Sci. Press, vol. 117, no. 1, July 6, 1918, pp. 23-24, 1 fig. The effect of water in concrete.

Water and Its Influence on Concrete Mixing. Building News, vol. 115, no. 3314, July 10, 1918, p. 30, 1 fig. Series of tests carried out in the Structural Materials Research Laboratory of the Lewis Institute, Chicago.

Finishes

Problems in Devising a New Finish for Concrete. J. J. Earley. Eng. & Cement World, vol. 13, no. 3, August 1, 1918, pp. 30-32. Abstract of a paper before the Am. Concrete Inst.

Form Work

Efficiency Methods in Form Work. A. B. McDaniel. Concrete, vol. 13, no. 2, August 1918, pp. 61-64, 4 figs. Make-up of forms; erection of forms; wrecking; cost of work.

See also Coal Industry (Mine Concreting); Roads and Pavements (Concrete Pavements).

CHEMICAL TECHNOLOGY

Ammonium Sulphate from Gas Works

Alkali Works Chief Inspector's Report. Gas Jl., vol. 143, no. 2878, July 9, 1918, pp. 62-63. Consideration of the direct process of sulphate of ammonia manufacture in gas works.

Estimation of Polysulphide. W. S. Curphey. Gas Jl., vol. 143, no. 2878, July 9, 1918, p. 69. From author's 1917 annual report as chief alkali inspector.

The Direct Process of Sulphate Making in Gas Works. W. S. Curphey. Gas Jl., vol. 143, no. 2878, July 9, 1918, pp. 68-69. From author's 1915 and 1916 annual reports as chief alkali inspector. (To be continued.)

Analysis

A Standard Apparatus for the Determination of Sulfur in Iron and Steel by the Evolution Method. H. B. Pulsifer. Jl. Indus. & Eng. Chem., vol. 10, no. 7, July 1, 1918, pp. 545-550, 3 figs. Description of the apparatus for determinations by the evolution method using concentrated HCl.

Iodide Copper Method with Sodium Fluoride. A. L. Reese. Eng. & Min. Jl., vol. 105, no. 26, June 29, 1918, p. 1170. Details of a process of determining copper by the iodide process in which the interference of ferric salts is prevented by the addition of sodium fluoride.

Rapid Determination of Carbon in Steel by the Barium Carbonate Titration Method. J. R. Cain and L. C. Maxwell. Jl. Indus. & Eng. Chem., vol. 10, no. 7, July 1, 1918, pp. 520-522. Method developed by Bureau of Standards for use where speed is important.

The Perchlorate Method for the Determination of the Alkali Metals. F. A. Gooch and G. R. Blake. Chem. News, vol. 117, no. 3048, May 24, 1918, pp. 196-198. Desirability of including potassium within the scope of the investigation of the perchlorate precipitation of rubidium and caesium.

Nitrogen Compounds

Nitrogen and Its Compounds. Horace Freeman. Chem. News, vol. 117, nos. 3049 and 3051, June 7, 1918, pp. 205-207. Early attempts to utilize atmospheric nitrogen; discovery of cyanamide; development of the arc process; the Haber process; establishment of the cyanide process in America; July 5, 1918, pp. 231-233. Manufacture of cyanamide and uses of its derivatives. Address before Board of Trade of Niagara Falls, Ont. From the Can. Chem. Jl.

The Formation of Nitrites from Nitrates in Aqueous Solution by the Action of Sunlight, and the Assimilation of the Nitrites by Green Leaves in Sunlight. Benjamin Moore. Proc. Royal Soc., vol. 90, no. B627, June 1, 1918, pp. 158-167. Report of experimental work and compilation of thermochemical determinations.

Potash Recovery

Recovery of Potash. Eng. & Cement World, vol. 13, no. 2, July 15, 1918, p. 68. Chemical and commercial methods for recovering potash from silicates.

Tanning

The Chrome-Tanning Industry. Chem. News, vol. 117, no. 3051, July 5, 1918, pp. 233-235. Processes and reputed advantages.

CLAY

(See Brick and Clay)

COAL INDUSTRY

Coke and By-Products

Coke-Oven By-products in 1917. Colliery Guardian, vol. 116, no. 3002, July 12, 1918, pp. 69-70. Report made under the Alkali Works Act.

Development of the Coke Industry in Colorado, Utah and New Mexico. F. C. Miller. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1307-1310.

Recovery of By-products in Coke Manufacture. M. Meredith. Coal Age, vol. 14, no. 2, July 13, 1918, pp. 60-62. Increased use of by-product ovens in Britain; the by-products recovered.

Loading and Handling

An Unloading Tower and Reloading Plant. J. O. Durkee. Coal Industry, vol. 2, no. 8, August 1918, pp. 299-302, 4 figs. Unloading, screening, storing and loading coal at the Island Creek Coal Co.'s plant on the Ohio river at Sekitan.

Marcus Screens at Plants of Carnegie Coal Co., Pennsylvania. Richard G. Miller. Coal Age, vol. 14, no. 4, July 25, 1918, pp. 171-174, 7 figs. Description of coal-cleaning plants.

Mine Concreting

Concrete Foundations, Drift Linings and Reservoirs. J. F. Springer. Coal Age, vol. 14, no. 5, August 1, 1918, pp. 204-210, 8 figs. Suggestions for the use of concrete in and around mines.

Mine Conveying

A Suggestion for Increasing Coal Production. H. D. Levin. Coal Age, vol. 14, no. 3, July 20, 1918, pp. 104-105, 3 figs. Use of light, easily portable loading conveyors suggested.

Mining

A Successful Labor-Saving Machine. N. L. Harmon. Coal Industry, vol. 2, no. 8, August 1918, pp. 290-292, 2 figs. Automatic safety mine-car cages and feeder built by an Ohio concern.

Coal Mining in British Columbia. R. Dunn. Coal Age, vol. 14, no. 2, July 13, 1918, pp. 55-57. New development hampered by cost of material and lack of men. Sales statistics for 1916 and 1917.

Electric Labor-Saving Devices in Coal Mining. Graham Bright. Coal Age, vol. 14, no. 3, July 20, 1918, pp. 116-120, 13 figs.

How Electrical Methods are Speeding Up Coal Mining Operations. Elec. Rec., vol. 24, no. 2, August 1918, pp. 21-23. Details of electrical haulage methods and equipment now used in different mines in Western Pennsylvania and Ohio.

Improvements in Coal Mining Methods. H. H. Stoek. Coal Industry, vol. 2, no. 8, August 1918, pp. 286-289, 5 figs. Suggestions regarding the method of underground mining considering the roof, floor and inclination of seam.

Increased Coal Output by Stripping. A. C. Vicary. Coal Age, vol. 14, no. 3, July 20, 1918, pp. 94-96, 4 figs. Advocates use of this method wherever possible.

Model Safety-First Coal Mine in Central Illinois. Coal Age, vol. 14, no. 1, July 6, 1918, pp. 4-10, 10 figs. Features of the Madison Coal Corporation's mine.

Some of the Coal Producer's Problems. D. H. McDougall. Can. Min. Jl., vol. 39, no. 11, June 1, 1918, pp. 183-184. Presidential address before the Mining Society of Nova Scotia.

The Eastern Middle-Anthracite Field. E. B. Wilson. Coal Industry, vol. 2, no. 8, August 1918, pp. 292-294, 4 figs. Third of a series on practical geology, describing and giving thickness, area and level of the measures of the eastern middle Pennsylvania anthracite coal field.

Working a Thin Seam by Coal Cutters and Face Conveyors. S. T. Boam. Iron & Coal Trades Rev., vol. 97, no. 2627, July 5, 1918, pp. 12-13, 2 figs. From a paper before the South Midland Branch of the Nat. Assn. of Colliery Managers.

Trip Feeders

Trip Feeders. C. L. Miller. Coal Industry, vol. 2, no. 8, August 1918, pp. 307-308, 3 figs. Formulae, curves, data and drawings for trip-feeder design.

Washing

The Emergency and Clean Coal. G. H. Elmore. Coal Age, vol. 14, no. 3, July 20, 1918, pp. 122-126, 8 figs. Suggests more modern coal washeries.

See also Fuels and Firing (Coke).

CONVEYING

(See Hoisting and Conveying)

COOLING

Cooling of Condenser Water by Towers and Spraying. E. W. Marriott. Indus. Australian & Min. Standard, vol. 59, no. 1544, June 13, 1918, pp. 621-622, 6 figs.

DRYDOCKS

Construction of Pearl Harbor Drydock Completed. Eng. News-Rec., vol. 81, no. 4, July 25, 1918, pp. 173-177, 7 figs. Novel method of placing unit sections of concrete base and walls from floating drydock and building upper works in movable cofferdams.

EARTHWORK

Excavations

Blasting Methods at Ajo. S. U. Champe. Min. & Sci. Press, vol. 117, no. 2, July 13, 1918, pp. 46-48, 6 figs. Description of ore excavation methods.

Blasting Methods at Ajo. S. U. Champe. Western Eng., vol. 9, no. 8, August 1918, pp. 326-328, 6 figs. Methods of preparing the ground to receive the charges for blasting employed in the copper mountain deposit at Ajo, Ariz., belonging to the New Cornelia Copper Co.

The Tailing Excavator at the Plant of the New Cornelia Copper Co., Ajo., Ariz. F. Moeller. Tran. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1229-1234, 6 figs. Extension of the use for which the mechanical unloader was first designed.

Levee Construction

Levee Construction in North Texas with Draglines. O. W. Finley. Eng. & Contracting, vol. 50, no. 3, July 17, 1918, pp. 65-66. A description of reclamation work with cost figures and present values.

ELECTRICAL ENGINEERING

Alternating-Current Engineering

Characteristic Curves and Conditions of Stability of an Operating System. (Sur les courbes caractéristiques et les conditions de stabilité des régimes). J. Bethenod. Revue Générale de l'Electricité, vol. 4, no. 2, July 13, 1918, pp. 35-36, 1 fig. Study of a particular case of spontaneous inception of oscillatory phenomena.

Batteries

Dry Cells and Wet Batteries. William J. Herdman. Electricity, vol. 32, no. 1443, July 5, 1918, p. 355. Care of Lalande Cells. (Continued.)

Eddy Currents

On Copper and Iron Losses in Alternating Current Machine with Deep Slots (in Japanese). T. Isshiki. Denki Gakkwai Zasshi, no. 358, May 31, 1918.

Hysteresis Losses in Iron (Remarque sur les pertes dans le fer par hystérésis). M. Latour. Revue Générale de l'Electricité, vol. 4, no. 2, July 13, 1918, pp. 36-37. Determination of the relation between the hysteresis angle τ and the Steinmetz coefficient η. Remarks on a similar study by the same writer published in the issue of April 13, 1918.

Electric Furnace

The Manufacture of Ferro-Alloys in the Electric Furnace. R. M. Keeney. Tran. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1321-1373. Processes followed in the manufacture of ferrochrome, ferromanganese, ferromolybdenum, ferrotungsten, ferrovanadium and ferrouranium.

Electrodeposition of Metals

The Deposition of Nickel Upon Cast Iron from a Hot Electrolyte. Royal F. Clark. Metal Industry, vol. 16, no. 7, July 1918, p. 309. From a paper before the Electro-Platers Society, July 1918.

The Maintenance of High Ampere Efficiency in Electrolytic Copper Refining. M. H. Merriss and M. A. Mosher. Eng. & Min. Jl., vol. 106, no. 3, July 29, 1918, pp. 95-99, 8 figs. Practical notes on methods to secure high ampere efficiency, details as to correct method of hanging and controlling sheets; use of volt-meter to detect short-circuits and bad contacts.

Electrolysis

Electrolysis Mitigation. Scientific Am. Supp., vol. 86, nos. 2220 and 2221, July 20, 1918, pp. 46-47; Discussion of causes and methods of regulating electrolytic conditions of underground structures; July 27, p. 58; Essentials in electrolysis regulations.

Generators

Rewinding and Reconnecting Direct Current Armature Windings for a Change in Voltage. T. Schutter. Elec. Eng., vol. 52, no. 1, July 1918, pp. 45-48, 5 figs. Describes practical methods.

Heating

Electrically Heated Devices. Elec. Rec., vol. 24, no. 2, August 1918, pp. 82k-82r. Tables giving trade name, size or capacity, wattage, number of heat-units, cost to operate, voltage and retail price of electrically heated devices.

High-Frequency Currents

On the Discharge Between Metallic Electrodes and Continuous Electric Oscillations. H. Yagi. Jl. of the College of Engineering, Tokyo Imp. Univ., vol. 9, no. 4, February 28, 1918, pp. 115-152, 27 figs. Experiments on discharges in air and in coal gas; oscillations; Wien's quenched spark gaps; secondary oscillation; fluctuation of the secondary current.

Radiotelegraphy. G. E. Mitchell. Scientific Am. Supp., vol. 86, no. 2223, August 10, 1918, pp. 88-90. Uses and possibilities of radiotelegraphy in the war.

Wave Velocity and Capacity of Horizontal Helices in Wireless Telegraphy and Transmission Line Protective Apparatus. A. Press. Elecn., vol. 81, no. 6, June 7, 1918, pp. 106-107. A mathematical treatment.

High-Tension D. C. Current

Very High Tension Direct Current for Laboratory Use (La production du courant continu à très haute tension pour laboratoire d'essai). Jean Saroléa. Revue Générale de l'Electricité, vol. 4, no. 1, July 6, 1918, pp. 4-8, 3 figs. Description of apparatus to obtain very high-tension continuous currents in a laboratory by means of Fleming valves.

Insulators

Extra-High-Tension Insulators (in Japanese). H. Tachikawa. Denki Gakkwai Zasshi, no. 359, June 30, 1918. Paper read before the meeting of Tokyo Local Section. (Continued.)

Lamps

Management of Lamp Works. T. Nakagawn (in Japanese). Denki Gakkwai Zasshi, no. 354, January 1918, pp. 97-105.

Proposed Standardization of the Thread of Edison Base Lamps (Projet d'unification des filetages des culots de lampes à vis Edison). Ch. Zetter. Revue Générale de l'Electricité, vol. 4, nos. 1-4, July 6-27, 1918, pp. 9-21, 39-49, 73-84, 105-112, 10 figs. Comparative notes on work done by the Commission of the Union of Syndicates of Electricity with reference to the standardization of small electrical appliances.

Lightning Arrester

New Type of Lightning Arrester Makes Its Appearance. Elec. Ry. Jl., vol. 52, no. 3, July 20, 1918, pp. 101-102, 4 figs. The "oxide film" arrester has general properties of the aluminum cell arrester with additional features.

Magnetism

Hypothetical Theory on Magnetization of Magnetic Substances (in Japanese). T. Takeuchi. Denki Gakkwai Zasshi, no. 358, May 31, 1918.

Magnetic Susceptibility and Electric Resistivity. F. H. Loring. Chem. News, vol. 117, no. 3051, July 5, 1918, pp. 229-231, 4 figs. Additional notes to a previous general paper on magnetic susceptibility.

Motors

Indirect Construction of the Precise Diagram for Rotating Field Motors. (Construction indirecte du diagramme rigoureux des moteurs à champ tournant). V. Genkin. Revue Générale de l'Electricité, vol. 3, no. 26, June 29, 1918, pp. 931-933, 4 figs. Graphical construction of the cyclic diagram of a rotating field motor, taking into consideration the resistance of the stator.

On the Sub-Synchronous Speed of Squirrel-Cage Induction Motors (in Japanese). L. Takeshi. Denki Gakkwai Zasshi, no. 356, March 31, 1918.

Precipitators

Electrical Precipitation from Flue Gas. Iron Age, vol. 102, no. 5, August 1, 1918, p. 273, 3 figs. High-voltage direct current passed through chains hanging in flue from a copper refinery electrifies metallic particles, projecting them against grounded wall where they drop into hoppers.

New Electrical Precipitation Treater (in Japanese). M. Shibusawa. Denki Gakkwai Zasshi, no. 354, January 1918, pp. 61-87.

Resistance and Light

Substances of Variable Resistance Under the Action of Light (Corps à résistivité variable sous l'action de la lumière). M. Case. Revue Générale de l'Electricité, vol. 3, no. 25, June 22, 1918, p. 889. Process employed to find other substances than selenium of variable resistance under the action of light; results obtained.

Roentgen Rays

Discussion on Recent Development of Roentgen Radiation (in Japanese). Denki Gakkwai Zasshi, no. 355, February 1918, pp. 167-171.

Rotary Converters

Starting Rotary Converter. F. D. Newbury and M. W. Smith. Power Plant Eng., vol. 22, no. 12, June 15, 1918, pp. 499-500, 2 figs. Comparison of results with transformer secondaries connected to collector rings and when alternating-current circuit is open.

Starting Rotary Converters. W. R. Bowker. Elec. Eng., vol. 52, no. 1, July 1918, pp. 40-42, 10 figs. Analysis of the problem and exposition of present methods used to solve it.

Storage Battery

Developments in the Use of Storage Batteries. G. F. Wakeman. Jl. of Elec., vol. 41, no. 3, August 1, 1918, pp. 120-121. Some of the present applications and future possibilities.

Switchgear

Automatic Control of Electric Heaters, Valves and Similar Apparatus. G. E. Palmer. Electricity, vol. 32, no. 1442, June 28, 1918, pp. 341-342, 2 figs. Diagrams of switch connections for automatic control of electric heaters, valves, etc.

Some Considerations Relating to Large Power Station Switchgear. H. W. Clothier. Elecn., vol. 81, no. 9, June 28, 1918, pp. 175-179, 11 figs. Deals particularly with oil switches for large outputs. Controlling factors in design. Drawings of a form of switchgear in successful operation and suitable for use in a station of 60,000 kw.

Three- and Four-Way Switch Circuits. Terrell Croft. Elec. Eng., vol. 52, no. 1, July 1918, pp. 19-21. Diagrams and explanations of the wiring connections for several three- and four-way circuits. (To be continued.)

Telephones

Leeds Automatic Exchange. J. Hedley. Elecn., vol. 81, no. 5, May 31, 1918, pp. 84-87, 6 figs. Description of a new telephone exchange of the full automatic Strowger type, five-figure system.

New Private Branch Exchange Switchboard of Bell System (in Japanese). S. Osada. Denki Gakkwai Zasshi, no. 357, April 30, 1918.

Transformers

Discussion on Resonance Phenomena in High Voltage Transformers (in Japanese). H. Yagi. Denki Gakkwai Zasshi, no. 354, January 1918, pp. 131-135.

Higher Harmonics in the Magnetizing Current of a Single Phase Transformer (in Japanese). K. Takamoto. Denki Gakkwai Zasshi, no. 355, February 1918, pp. 171-191.

Outdoor Water-Cooled Transformers. R. von Fabrice. Power, vol. 48, no. 6, August 6, 1918, pp. 198-199, 1 fig. Necessary equipment to handle oil and to furnish a suitable cooling-water supply for outdoor water-cooled oil-insulated transformers.

Resonance Phenomena in High Voltage Transformers (in Japanese). K. Nishi. Denki Gakkwai Zasshi, no. 358, May 31, 1918. (Continued.)

Transmission Lines

Air Break Switches and Auxiliary Equipment for Outdoor Substations. Elec. Rec., vol. 24, no. 2, August 1918, pp. 42-51. Diagrams and illustrations of present types.

Characteristics of Iron and Steel Conductors. Charles E. Oakes and P. A. B. Sahm. Elec. World, vol. 72, no. 4, July 27, 1918, pp. 150-151. Complete test data for calculation of electrical characteristics of iron and steel conductors.

Charging Currents and Earthing Devices in Transmission Lines. H. Behrend. Elecn., vol. 81, no. 11, July 12, 1918, pp. 222-223, 3 figs. Abstract of an article in the Elektrotechnische Zeitschrift, no. 25, 1917.

Computation of Inductive Circuits in Parallel (Calcul des circuit inductifs en dérivation). H. Pécheux. Revue Générale de l'Electricité, vol. 3, no. 25, June 22, 1918, pp. 891-894, 5 figs. Attempt to show that it is possible to solve problems of technical electricity by means of vectors and projections without using imaginary quantities.

Connections of Subterranean High-Tension Cables (Juntas de los cables subterráneos a alta tensión). H. Aldum. Boletin de la Asociacion Argentina de Electro-Técnicos, vol. 4, no. 2, February 1918, pp. 639-645. Résumé of a conference before the Physics Institute of La Plata. (To be continued.)

Heating of Underground Cables (in Japanese). T. Yoneda. Denki Gakkwai Zasshi, no. 357, April 30, 1918.

On the Abacus for Calculating the Resistance of Parallel Conductors (Sur les abaques relatifs au calcul de la resistance des conducteurs associés en parallele). L. Zoretti and J. Bethenod. Revue Générale de l'Electricité, vol. 3, no. 26, June 29, 1918, pp. 933-934. Remarks on M. Custex's article on the resistance of parallel conductors published in issue of March 23.

On the Distribution of Potential Along the String of the Suspension Insulator (in Japanese). H. Sagusa. Denki Gakkwai Zasshi, no. 357, April 30, 1918.

Practical Study of Transmission Lines by Means of Hyperbolic Functions with Imaginary Variables (Calcul pratique des lignes de transmission électriques par les fonctions hyperboliques des variables imaginaires). G. Viard and M. Latour. Revue Générale de l'Electricité, vol. 4, no. 3, July 20, 1918, pp. 67-71, 3 figs. Review of the computations for transmission lines by means of hyperbolic functions with imaginary variable quantities; description of a graph which permits the determination of the tension and the current at any point in a transmission line, taking into consideration the resistance, inductance, capacity and losses of the line.

Providing Strength and Attractiveness in Special Overhead Supports. Charles R. Harte. Elec. Ry. Jl., vol. 52, no. 3, July 20, 1918, pp. 92-95, 12 figs. Discussion of various types of overhead bridges and other special structures.

Public Safety and High and Low Tension Overhead Transmission Systems (La seguridad pública y las lineas aéreas de alta y baja tension). F. Linderman. Boletin de la Asociacion Argentina de Electro-Técnicos vol. 4, no. 1, January 1918, pp. 617-621. Recommendations of several practices in the arrangement of transmission systems.

Sag Calculation for Iron Wire Lines. M. D. Leslie. Elec. World, vol. 72, no. 5, August 3, 1918, pp. 196-197, 1 fig. Stringing iron wire with less sag suggested as a practicable war-time economy where the usual safety factor is not essential and weather conditions are not severe. A formula to apply is given.

The Test Sheath Cable and Its Potentialities. C. J. Beaver. Elecn., vol. 81, no. 10, July 5, 1918, pp. 204-205, 3 figs. Description of a construction such that injurious effects from outside and leakage from inside the cable are bound to be interrupted by the test sheath conductor.

See also Foundry (Electric Furnace); Hydraulics (Hydroelectric Plants); Marine Engineering (Electric Propulsion); Metallurgy (Copper Refining); Motor-Car Engineering (Electric Vehicles); Physics (Electricity); Power Generation (Electric Power Applications).

ENGINEERING MATERIALS

Boiler Plates

A Cause of Failure in Boiler Plates. Walter Rosenhain and D. Hanson. Engineering, vol. 105, no. 2738, June 21, 1918, pp. 692-694, 8 figs. The failure of a boiler plate in the last stages of manufacture accounted for by the phenomena of grain growth in the steel. From a paper read before the Iron & Steel Inst.

Brass

Brass Weakness. James Scott. Metal Industry, vol. 16, no. 7, July 1918, pp. 319-320, 3 figs. A microscopical explanation.

Bronze

Manganese in Aluminum Bronze. Charles Vickers. Brass World, vol. 14, no. 7, July 1918, pp. 202-203, 2 figs. Effect of manganese in aluminum bronze; results of tests.

Cast Iron

Cast Iron at High Temperatures. Power, vol. 48, no. 4, July 23, 1918, pp. 120-121, 3 figs. Data from several sources, with curves.

Malleable Cast Iron. E. Turner. Page's Eng. Weekly, vol. 32, no. 720, June 28, 1918, pp. 304-306. Methods of producing malleable cast iron and theory of the malleableizing process. (To be continued.) Paper presented at a meeting of the West of Scotland Iron and Steel Institute.

Glass

Strength of Circular Flat Plate of Glass. W. Richards. Mechanical World, vol. 63, no. 1637, May 17, 1918, p. 235, 1 fig. Account of the testing of a piece of ordinary plate glass.

Non-Ferrous Alloys

The Hardness of Alloys of Non-Ferrous Metals. P. Ludwik. Brass World, vol. 14, no. 7, July 1918, p. 207. Compilation of experimental results.

Road Materials

Apparent Specific Gravity of Fine Non-Bituminous Highway Material. Good Roads, vol. 16, no. 6, pp. 48-52, 2 figs. Tentative tests proposed by Committee D-4 of the Am. Soc. of Testing Materials for sand, stone and slag screenings and similar materials.

Rubber

Vulcanization of Rubber by Selenium. Charles R. Boggs. Chem. News, vol. 117, no. 3048, May 24, 1918, pp. 199-200.

Tungsten

Raw Materials Necessary in the Electrical Industry: Tungsten (De quelques matières premières nécessaires à l'industrie électrique: le tungstène). D. Pector. Revue Générale de l'Electricité, vol. 4, no. 3, July 20, 1918, pp. 87-94. History and metallurgy of tungsten; principal deposits of its ore. (To be continued.)

Wire Rope

Splicing Wire Rope. Western Eng., vol. 9, no. 8, August 1918, pp. 313-314. Sketches explaining splicing in its different stages. Abstract from Leschen's "Hercules," March 1918.

The Factor of Safety of Wire Ropes. S. A. Mining Jl. & Eng. Rec., vol. 27, no. 1393, June 8, 1918, pp. 146-147. Discussion of a previous paper giving empirical values for the factor of safety of wire ropes used for winding in mine shafts. (To be continued.)

Wood

Relative Resistance of Various Hardwoods to Injection with Creosote. Ry. Rev., vol. 63, no. 3, July 20, 1918, pp. 79-86, 12 figs. From Bul. 606, U. S. Dept. of Agriculture by Clyde H. Teesdale and J. D. McLean.

See also Aeronautics (Materials of Construction); Building and Construction (Sandstone; Cement and Concrete; Fuels and Firing (Soot Cleaners); Refractories; Roads and Pavements (Road Materials); Steel and Iron (Vina Steel).

FACTORY MANAGEMENT

Non-Repetitive Work

Managing Non-Repetitive Work. Norman Howard. Indus. Man., vol. 56, no. 1, July 1918, pp. 55-58. How conditions and operations can be standardized for tool-making and machine-shop repairs.

Shifts

Changing Power Plant Shifts. J. C. Hawkins. Power, vol. 48, no. 6, August 6, 1918, pp. 202-203, 1 fig. How a schedule of change of watches was arranged in a plant employing three shifts, each working 8 hr. each.

Shop Management

Working Out a Theory in Shop Management. Am. Mach., vol. 49, no. 4, July 25, 1918, pp. 145-147. The method of the White Motor Co. in running the shop on commission and giving the men a direct voice in the management.

Workmanship as an Efficiency Aim. C. W. Starker. Indus. Man., vol. 56, no. 1, July 1918, pp. 25-26. Points out the danger of sacrificing workmanship for money-making instinct and quantity output in the wrong application of efficiency schemes.

Special Work

Money-Saving Factors in the Maintenance of Special Work. R. C. Cram. Elec. Ry. Jl., vol. 52, no. 3, July 20, 1918, pp. 103-108, 11 figs. Necessity of intelligent selection of special work, careful workmanship in installation and accurate records of performance and prompt attention to repairs.

FOUNDRY

Brass Furnace

The Care of the Brass Furnace. J. A. Fletcher, Jr. Metal Industry, vol. 16, no. 7, July 1918, p. 310, 1 fig. The experience of a large foundry with high-melting-point metals.

Castings

Electric v. Converter Castings. C. R. Messenger. Page's Eng. Weekly, vol. 33, no. 722, July 12, 1918, p. 17. Figures and facts based on 2029 tests with an electric, and 2436 with a converter, furnace. From a paper read before the Am. Foundry Men's Assn.

Manufacturing Heavy Malleable Iron Castings. A. Walter Lorenz. Foundry, vol. 46, no. 312, August 1918, pp. 350-351, 2 micrographs.

Cupola

Advantages Offered by the Oil-Fired Cupola. W. S. Dickson. Foundry, vol. 46, no. 312, August 1918, pp. 381-382, 2 figs. In the process described, crude oil is sprayed directly onto the coke bed to increase the heat and reduce the amount of coke used.

Electric Furnace

The Webb Electric Steel Furnace. Iron Age, vol. 102, no. 5, August 1, 1918, pp. 257-260, 4 figs. A high-voltage unit developed and operated by the Old Dominion Iron & Steel Corporation; low-carbon steel for engine bolts.

Grinding

The Economical Foundry Use of Grinding Wheels. W. T. Montague. Foundry, vol. 46, no. 312, August 1918, pp. 362-367, 8 figs. What wheels to use and how they should be operated to obtain the best results in casting work; safety factors. Paper read at the Metals division of the Am. Inst. of Min. Engrs.

Molding

Why the Inclined Mold is a Fallacy. R. R. Clarke. Foundry, vol. 46, no. 312, August 1918, pp. 351-352.

Patternmaking

Emergency Patterns for a Seven-Foot Gear. J. L. Gard. Foundry, vol. 46, no. 312, August 1918, p. 361, 2 figs.

Making a Pattern for a Gas Engine Cylinder. Frank B. Raebig. Foundry, vol. 46, no. 312, August 1918, pp. 383-385, 14 figs. Construction of core boxes also described, as well as two methods of molding (with necessary pattern changes).

Patternmaking and Molding Cast Tooth Gears. Jabez Nall. Foundry, vol. 46, no. 312, August 1918, pp. 377-380, 9 figs. Practice of a generation ago contrasted with that of today and a gear-molding machine discussed.

Sand Blast

The Sand Blast in the Foundry. H. L. Wadsworth. Brass World, vol. 14, no. 6,

June 1918, pp. 174-175. Two classes of sand blasting; rotary table machines; kinds of abrasives; suggestions as to compressors. From a paper read before the Am. Foundrymen's Assn.

Welding

Welding Propellers in Panama Canal Foundry. John H. Moffett. Foundry, vol. 46, no. 312, August 1918, pp. 356-358, 6 figs. How blades are repaired by burning-on, with a comparison of costs with autogenous processes; making the molds and pouring the metal.

FORGING

Electric Power

The Electrical System of the Forge Shop. Edward McLlvried. Am. Drop Forger, vol. 4, no. 7, July 1918, pp. 271-272, 1 fig. Applications of electric power and discussion of two methods of driving machinery.

Electric Steel

Electric Steel for the Forging Industry. Arthur V. Farr. Am. Drop Forger, vol. 4, no. 7, July 1918, pp. 264-267, 6 figs. Two methods of manufacturing electric steel.

Forge-Shop Design

The Problem of Forge Shop Design. J. T. N. Hoyt. Am. Drop Forger, vol. 4, no. 7, July 1918, pp. 262-263, 3 figs. Typical examples of forge-shop designs and detailed descriptions of construction.

Hollow Forgings

Development of Flaws in Hollow Forgings. A. S. Hesse. Am. Mach., vol. 49, no. 4, July 25, 1918, pp. 153-154, 3 figs. Improper methods of forging which develop flaws in hollow forgings such as gun tubes. Proper remedies suggested.

Quenching Oils

Question of Quenching Oils for Forgings. George W. Pressell. Am. Drop Forger, vol. 4, no. 7, July 1918, pp. 273-277, 6 figs. Report of experiments showing values of different substances in quenching steel.

FUELS AND FIRING

Chimneys

Tall Chimneys in Metallurgical Plants. Eng. & Min. Jl., vol. 106, no. 4, July 27, 1918, pp. 168-171, 13 figs. List of world's tallest chimneys in metallurgical plants.

Coal

Coal—Its Origin and Composition. H. B. Miller. Queensland Government Min. Jl., vol. 19, no. 217, June 15, 1918, pp. 263-265. Length of time to form 1 ft. of peat, interval between coal beds, data on sulphur in coal and calorific value of coal.

Coal Analysis

Analysis of Canadian Fuels. (In five parts.) Bulletins 22-26, Canada Department of Mines, Mines Branch. Tables giving the composition, condition and value of samples from each one of the areas in the coal districts of Canada.

Determination of Volatile Matter and Ash in Coal. Norton H. Humphrys. Gas World, vol. 68, no 1771, June 29, 1918, pp. 436-437. Proposed device and procedure.

Coal Evaluation

An Alinement Chart for the Evaluation of Coal. A. F. Blake. Jl. Indus. & Eng. Chem., vol. 10, no. 8, August 1, 1918, pp. 627-629, 1 fig. Chart for determining the relative values of different coals, given the price per ton and the chemical analysis.

Coal Selection

Coal and Its Selection—A Factor in Power Plant Management. R. June. Concrete (Cement Mill Section), vol. 13, no. 2, August 1918, pp. 16-19, 4 figs. Classification of coals; question of size; influence of moisture; ash problem; heating value; purchase of coal under specifications.

Coal Storage

Detailed Facts About Storing Soft Coal. H. H. Stoek. The Black Diamond, vol. 61, no. 3, July 20, 1918, pp. 48-49, 4 figs. Suggestions for obviating the difficulties and dangers in storing soft coal. (Concluded.)

Storing Coal at Mooseheart, Illinois. Power, vol. 48, no. 3, July 16, 1918, pp. 76-78, 2 figs. A flexible system of portable conveyors. Circular systems of piling. Estimated cost of storing and reclaiming 20 cents per ton.

Coke

Mechanical Condition of Blast Furnace Coke. G. D. Cochrane. Iron Age, vol. 102, no. 4, July 25, 1918, pp. 202-203, 1 fig. Machine for testing hardness; effect on coke consumption in blast furnaces; action of gases on hard and soft coke. From a paper read before the Iron & Steel Inst., London, May 1918.

Fuel Saving

Concrete Examples of Coal Conservation. H. E. Dart. The Locomotive, vol. 32, no. 2, April 1918, pp. 34-43, 2 figs. How the Hartford Steam Boiler Inspection and Insurance Co. has reduced the average coal consumption in its office building by about 25 per cent. (From the Hartford Courant.)

Fuel Saving in Power Plants. Railroad Herald, vol. 22, no. 8, July 1918, pp. 164-165. Fundamentals of the approved national plan of organization in connection with conservation of fuel in power plants throughout the United States.

Fuels. E. R. Knowles. Steam, vol. 22, no. 2, August 1918, pp. 35-41, 4 figs. Classification of fuels and study of their respective features.

Furnaces

Adapting Furnaces to Available Fuel. Osborn Monnett. Power Plant Eng., vol. 22, no. 13, July 1, 1918, pp. 524-526, 7 figs. Proportions and arrangements of baffles in hand-fired furnaces.

Natural Gas

Gasoline from Natural Gas by Compression. W. P. Dykema. Compressed Air Mag., vol. 23, no. 8, August 1918, pp. 8852-8854. Theory of precipitation; condensation by cooling; condensation by compression; absorption theory; use of combination compression and refrigeration process. (From Bureau of Mines Bul.)

The Compression Process for Extracting Natural Gas from Gasoline. W. P. Dykema. Western Eng., vol. 9, no. 8, August 1918, p. 310. Data compiled from Bul. No. 151, issued by the U. S. Bureau of Mines on the Recovery of Gasoline from Natural Gas by Compression and Refrigeration.

Oil Fuel

Supply of Oil Available from Shales. G. Egloff and J. C. Morrell. Oil and Gas Jl., vol. 17, no. 10, August 9, 1918, pp. 46-48. Chemical constitution of clays, shales and slates.

What Substitution of Oil for Coal Can do. Steam, vol. 22, no. 2, August 1918, pp. 47-49. Results obtained at different plants in New England with fuel oil, which is being supplied them on account of the scarcity of coal.

Peat

Distillation of Peat. R. Hauser. Colliery Guardian, vol. 116, no. 3002, July 12, 1918, p. 72. Results of experiments on peat.

Powdered Coal

Coal Conservation in Fact. C. R. Knowles. Elec. Rev., vol. 72, no. 26, June 29, 1918, pp. 1078-1079. Writer believes coal in gaseous and pulverized form must eventually replace lump for true conservation.

Control of Combustible and Air in Burning Powdered Coal. W. G. Wilcox. Compressed Air Mag., vol. 23, no. 8, August 1918, pp. 8839-8841. Effect of grinding coal on its fuel efficiency and study of the methods for mixing air and powdered coal. From a paper read before the Western New York section of the Am. Chem. Soc.

Mixer and Feeder for Powdered Coal. Compressed Air Mag., vol. 23, no. 8, August 1918, p. 8842. "Lopulco" powdered fuel mixing and feeding apparatus of the Locomotive Pulverized Fuel Co., New York.

The Possibilities of Powdered Coal. W. G. Wilcox. Scientific Am. Supp., vol. 86, no. 2221, July 27, 1918, pp. 62-64. Report of experiments. Paper delivered before the Western New York Section of the Am. Chem. Soc.

Use of Pulverized Coal at the Bunker Hill and Sullivan Smelting and Refining Plant. C. T. Rice. Eng. & Min. Jl., vol. 106, no. 3, July 20, 1918, pp. 91-94, 6 figs. Holbeck return system for the use of pulverized coal, with application to boilers, furnaces and kettles.

Smokeless Combustion

Combustion and Smokeless Furnaces. J. W. Hays. Steam, vol. 22, no. 2, August 1918, pp. 44-46. Laws governing combustion; exposition of the different heat theories; mechanical equivalent of heat. (To be continued.)

The Carbonization of Bituminous Coal. C. T. Malcolmson. Coal Industry, vol. 2, no. 8, August 1918, pp. 295-297. Account of process for the manufacture of smokeless fuel followed during the last three years at Irvington, N. J., in a series of experiments conducted for Blair & Co. of New York. Paper to be presented before the Am. Inst. Min. Engrs.

Soot Cleaners

Why Cast Iron Protects Soot Cleaner Elements against High Temperature. Popular Engr., vol. 10, no. 1, July 1918, pp. 23-26, 6 figs. Study and conclusions of the Vulcan Soot Cleaner Co. of Du Bois, Pa.

See also Brick and Clay; Railroad Engineering, Steam (Locomotive Fuel).

GAS POWER

See Internal-Combustion Engineering; Fuels and Firing (Natural Gas); Producer Gas.

GAS PRODUCERS

(See Producer Gas)

HEATING

Boilers

Some Failures of Cast-Iron Heating Boilers. E. Mason Parry. The Locomotive, vol. 32, no. 2, April 1918, pp. 43-49, 5 figs. Example demonstrating the author's claim that the failure of cast-iron sections of a cast-iron boiler is due in practically every case to the overheating of surfaces exposed directly to the products of combustion, through allowing the water level in the boiler to recede below that which has been predetermined by the designer.

Electric

Electric Heating in Manufacturing. Thomas Robson Hay. Indus. Management, vol. 56, no. 1, July 1918, pp. 53-55. Advantages of electric heating and practical points in installing and operating electric heating equipment.

Heating Systems

Fuel Saving Heating Systems. Alfred G. King. Domestic Eng., vol. 84, no. 4, July 27, 1918, pp. 146-150, 3 figs. Details of construction of an accelerated hot water heating system.

Reasons for Failures of Heating Systems. J. D. Hoffman. Heat. & Vent. Mag., vol. 15, no. 7, July 1918, pp. 13-18. Effect of poor building construction; space restrictions in warm-air furnace heating. From a paper before the Am. Soc. of Heat & Vent. Engrs., Buffalo, June 1918.

Returning Condensation in High and Low Pressure Heating Systems. C. L. Hubbard. Domestic Eng., vol. 84, no. 6, August 10, 1918, pp. 197-198, 4 figs. Notes on various methods of saving condensation in both high and low-pressure heating systems. (To be continued.)

Hot-Water Service

Hot Water Service. M. W. Ehrlich. Power Plant Eng., vol. 22, no. 12, June 15, 1918, pp. 489-491, 3 figs. Outlines methods for calculating heating surface required.

Steam

Dripping One-Pipe Steam Heating Systems. Albert L. Baum. Power, vol. 48, no. 6, August 6, 1918, pp. 194-195, 6 figs. Ways of obviating noises and rendering quick heating an easy matter.

Substations

The Heating of Substations. R. von Fabrice. Power, vol. 48, no. 4, July 23, 1918, pp. 129-130. Considers the heat losses from the electrical equipment and gives a practical illustration.

Temperature Control

Temperature Control in Modern Heating Systems. Charles L. Hubbard. Domestic Eng., vol. 84, no. 3, July 20, 1918, pp. 78-81, 22 figs. Notes on the installation and operation of temperature regulating devices and their value in connection with fuel conservation. (Continued.)

Workshops

Factory Heating. C. L. Hubbard. Steam, vol. 22, no. 2, August 1918, pp. 33-35. Computations for heat loss and steam requirements. (To be continued.)

Steam-Heating of Workshops. Mechanical World, vol. 63, no. 1637, May 17, 1918, pp. 236-237. Factors involved in the calculation of the size of heating apparatus necessary for a given building.

The Heating and Ventilation of Workshops. Engineer, vol. 126, no. 3262, July 5, 1918, pp. 4-5, 1 fig. Heating arrangements of a 927-ft. building.

See also Electrical Engineering (Heating).

HOISTING AND CONVEYING

Conveying Machinery

How to Move Materials by Machinery. Henry J. Edsall. Indus. Management, vol. 56, no. 1, July 1918, pp. 42-49, 22 figs. Application of various types of elevating and conveying machinery to the handling of coal, crushed stone, cement in bags, and packages and vegetables in a canning establishment, with a per hour capacity in each case.

Hoisting by Stages

Hoisting by Stages from Deep Mines. B. A. Balzari. Min. & Sci. Press, vol. 117, no. 2, July 13, 1918, pp. 57-58, 2 figs. Description of hoist at Argonaut mine, California.

Hoists

Practical Hints in Bucket-Elevator Operation. A. M. Nicholas. Queensland Government Mining Jl., vol. 19, no. 217, June 15, 1918, pp. 267-268. From a paper read before the Am. Inst. Min. Engrs.

The New Portland Municipal Elevator. Henry Blood. Eng. & Cement World, vol. 13, no. 3, August 1, 1918, pp. 19-22, 4 figs. Details of construction.

Loco Tractor

A New System of Transport. Engineer, vol. 125, no. 3261, June 28, 1918, pp. 550-552, 5 figs. Describes the Loco-Tractor, a special form of machine to replace the locomotive on pioneer light railways; guide trucks on rails with driving wheels rubber-tired run on prepared strips of road metal on each side of the track.

Steel Cables (Hoisting Ropes)

Hoisting with Steel Cables. E. Levy. Western Eng., vol. 9, no. 8, August 1918, p. 315. Causes of breakage of ropes and suggested directions to the master mechanic.

Hoisting with Steel Cables. Ernest Levy. Min. & Sci. Press, vol. 117, no. 1, July 6, 1918, p. 21. Reasons for breaking; directions to master mechanics for care of ropes; warnings to hoistmen.

Life and Care of Hoisting Ropes. Coal Age, vol. 14, no. 1, July 6, 1918, pp. 11-13. Suggestions as to the best rope; when to renew ropes; recutting and re-coning ropes to change point of recurring stress.

Winding Drums

The Strength of Winding Drums. John S. Watts. Power, vol. 48, no. 4, July 23, 1918, pp. 127-128, 1 fig. Mathematical calculations of the safe strength of a shell of a drum to carry more than one coil of rope, such as the drum of a hoisting or winding engine.

Winding Engines (Electric)

Electric Deliveries for the "Black Diamond." A. Jackson Marshall. Elec. Rev., vol. 73, no. 2, July 13, 1918, pp. 70-71, 2 figs. Data on comparative cost of electric, gasoline and horse delivery of coal.

Electric Winding Engines and Mine Hoists. H. H. Broughton. Elecn., vol. 81, no. 10, July 5, 1918, pp. 206-209, 2 figs. First of a series. Describes scope of work and gives notes of general interest on the question of power supply.

Motor-Driven Shaft-Hoist Installation. Coal Age, vol. 14, no. 2, July 13, 1918, pp. 50-54, 7 figs.

35-Ton Wagon Hoist at Acklam Works. Iron & Coal Trades Rev., vol. 97, no. 2629, July 19, 1918, p. 67, 3 figs. Description of an electrically driven hoist.

Wire Ropes

The Factor of Safety of Wire Ropes Used for Winding in Mine Shafts. J. A. Vaughn. Jl. of the South African Inst. of Engrs., vol. 16, no. 11, June 1918, pp. 196-200, 1 fig. Author's reply to discussion of his original article published in issue of November 1917.

See also Coal Industry (Mine Conveying); Engineering Materials (Wire Rope); Power Plants (Ash Conveyors).

HYDRAULICS

Lindsay Strathmore Irrigation Project. S. E. Kieffer. Eng & Cement World, vol. 13, no. 3, August 1, 1918, pp. 13-17. Special features in connection with lining of flume and canal with the cement gun on a large irrigation project.

Dams

Design of a Tilting Dam. V. B. Siems. Can. Engr., vol. 35, no. 4, July 25, 1918, pp. 79-81. Details of construction of the Loch Raven Tilting Dam built on the Gunpowder River, to increase the water supply of Baltimore, Md. From paper read before the Am. Water Works Assn.

Repair Washout Under Dam by Sheet Pile Cutoff Embedded in Concrete. Eng. News-Rec., vol. 81, no. 4, July 25, 1918, pp. 186-189, 2 figs.

Reservoir Dams. Engineering, vol. 105, no. 2738, June 21, 1918, pp. 687-689, 18 figs. A description of the geologic and engineering features of the Howden and Derwent dams of the Derwent Valley Waterworks.

Hydroelectric Plants

Automatic Hydro-Electric Generating Station. L. B. Bennett. Page's Eng. Weekly, vol. 33, no. 722, July 12, 1918, p. 18. Description of the automatic generating station recently put into operation by the Iowa Ry. & Light Co.

Construction Problems at Copco Plant. Elec. World, vol. 72, no. 5, August 3, 1918, pp. 201-202, 3 figs. Account of construction of an hydroelectric installation on the Klamath River, Oregon.

Electric Power for Mining in Yavapai County, Arizona. Eng. & Min. Jl., vol. 105, no. 25, June 22, 1918, pp. 1113-1116, 2 figs. Description of the Irving and Childs hydroelectric plants of the Arizona Power Co., having a fall of 1600 ft. and operating 250 miles of lines.

Hydroelectric Development in Iron Mountain Region. Elec. Rev., vol. 72, no. 25, June 22, 1918, pp. 1027-1028, 5 figs. Brief description of some developments in Michigan.

Modern Development of Large Hydro-Electric Power Schemes. C. Fred. Holmboe. Elecn., vol. 81, no. 8, June 21, 1918, pp. 142-147, 11 figs. The initial investigation of conditions; three cheap waterpower developments in detail.

Kutter's Formula

Algae Growths Increase Value of n in Kutter's Formula. Paul Taylor. Eng. News-Rec., vol. 81, no. 4, July 25, 1918, pp. 179-181, 6 figs. Studies made in 1912-16 in Tieton irrigation canal lined with reinforced-concrete lock indicate that growths raise n from 0.012 to 0.014.

Siphons

Mine Siphon Practice. Compressed Air Mag., vol. 23, no. 8, August 1918, pp. 8848-8849. Conditions to be observed in the installation and operation of mine siphons. (From Coal Age.)

Waterwheel Repairs

Utilize Dry Season to Overhaul Waterwheels. C. A. Graves. Elec. World, vol. 72, no. 5, August 3, 1918, p. 203, 3 figs.

See also Power Plants (Steam Hydro-electric Plant).

INTERNAL-COMBUSTION ENGINEERING

Cylinder Walls

Thickness of Cylinder Walls of Light Internal Combustion Engines. Akimasa Ono. Jl. of the Soc. M. E., Tokyo, vol. 21, no. 52, June 1918, pp. 21-34, 2 figs. Application of the general approximate theory of a thin cylindrical wall deformed symmetrically about the axis to the case of a cylinder wall partially subjected to internal pressure.

Diesel Engines

Tar Oil Fuel for Diesel Engines. Petroleum World, vol. 15, no. 213, June 1918, pp. 234-235. Report of The Heavy-Oil Engine Fuel Committee of the Diesel Engine Users' Assn., based on experimental comparisons of fuels. (Continued.)

The American Motorship "Oregon." Automotive Eng., vol. 3, no. 6, July 1918, pp. 266-270, 4 figs. Details of the construction of an American-built wooden ship equipped with two 650-hp. Diesel-type engines for main and auxiliary drives.

Werkspoor Marine Diesel Engines. Engineering, vol. 105, no. 2736, June 7, 1918, pp. 634-635, 7 figs. An illustrated description.

Heavy-Oil Engines

Rational Design for an Oil Engine. John F. Wentworth. Marine Rev., vol. 48, no. 8, August 1918, pp. 334-344, 8 figs. Study of the principles governing the selection of the different features in designing a marine oil engine and presentation of a design made according to the conclusions reached in the discussion.

The Heavy Oil Engine. Charles E. Lucke. Scientific Am. Supp., vol. 86, no. 2221, July 27, 1918, pp. 50-51. A review of the present construction and future development. Presented before the Engineers' Club of Philadelphia. (To be continued.)

The Heavy-Oil Engine from a Scientific Standpoint. Charles E. Lucke. Motorship, vol. 3, no. 8, August 1918, p. 24. (Concluded.)

Hvid Engine

Possibilities of the Hvid Engine. E. B. Blakely. Motorship, vol. 3, no. 8, August 1918, pp. 30-31. Requirements of the kerosene motor.

Ignition

Mechanical Construction of Ignition Magnetos. H. R. Van Deventer. Gas Eng., vol. 20, no. 8, August 1918, pp. 377-394, 26 figs. Paper read before a joint meeting of the National Gas Engine Assn. and the Soc. of Automotive Engineers, June 1918.

Low-Compression Engines

Some Features of Low-Compression Oil Engines. L. H. Morrison. Power, vol. 48, no. 4, July 23, 1918, pp. 123-127, 9 figs. Brief review of the principles of the two-stroke cycle type, various cylinder head designs, with their advantages and disadvantages, necessity for water injection, causes leading to scored cylinders.

Lubrication

Internal-Combustion Engine Lubrication and Lubricants. P. H. Conradson. Power, vol. 48, no. 3, July 16, 1918, p. 107. Abstract of paper read before the Am. Soc. for Testing Materials.

Lubrication and Fuel Economy. S. F. Lentz. Power Wagon, vol. 21, no. 165, August 1918, pp. 31-33. Conservation of motor fuel by the selection of a suitable lubricating oil. Paper read before the Nat. Gas. Eng. Assn.

Lubrication of Marine Heavy-Oil Engines. Motorship, vol. 3, no. 8, August 1918, pp. 9-15. Details of the leading types of lubricators.

Operating Costs

Operating Costs of Oil Engines. John Pierce. Power Plant Eng., vol. 22, no. 12, June 15, 1918, p. 504. Cost of fuel in cents per kw-hr. in one plant of about 2200 kw. capacity.

Sizes to Manufacture

The Number of Sizes of Engines to Manufacture. Theo. C. Menges. Nat. Gas Engine Assn. Bul., vol. 3, no. 12, July 1918, pp. 11-17. Curves showing the proportion of cubic feet of piston displacement, weight, cost and selling price, to the nominal horsepower of an engine. Paper read at the 11th annual meeting of the N. G. E. A. (To be continued.)

See also Aeronautics (Engines); Hoisting and Conveying (Loco Tractor).

IRON

(See Steel and Iron)

LABOR

British

British Railway Labor, Wages and Living Under Government Control. Ry. Rev., vol. 62, no. 24, June 15, 1918, pp. 863-867. Summary from report of railroad wage commission of phases of British railway experience.

Crippled Soldiers

The Return of the Crippled Soldier to Industrial Work. Am. Mach., vol. 49, no. 3, July 18, 1918, pp. 99-100. A discussion of the problem.

Housing Methods

Home Attractions Keep Track Laborers Satisfied. Clifford A. Elliott. Elec. Ry. Jl., vol. 52, no. 4, July 27, 1918, pp. 150-152, 4 figs. Solving the labor problem by providing free section houses with all conveniences, land for gardens and chicken raising, as well as free transportation to amusement places for employees and their families.

Man-Power Conservation

Conservation of Miners by Employment of Mechanical Equipment. R. L. Herrick. Coal Age, vol. 14, no. 4, July 25, 1918, pp. 162-167, 14 figs. Suggests many ways in which man power may be conserved by modern equipment.

Mutuality Plan

Oliver Iron Mining Co. Adopts Labor Cooperation Policy. Eng. & Min. Jl., vol. 105, no. 26, June 29, 1918, pp. 1166-1167. An account of the "mutuality" plan of the Oliver Iron Mining Co., establishing a medium whereby employees may make known their grievances and a mutual interchange of ideas may be brought about.

Physical Training

How Physical Training Helps Factory Executives. D. C. Stanbrough. Indus. Management, vol. 56, no. 1, July 1918, pp. 20-21, 2 figs.

Reading Rooms

Development of Santa Fe Reading Room System. Charles E. Parks. Ry. Age, vol. 65, no. 4, July 26, 1918, pp. 179-182, 10 figs. Reasons for its establishment; its activities and the good results that have been secured from it.

Schools

Coal-Mining Instruction in the Evening Schools of Derbyshire and Leicestershire. George Forster. Iron & Coal Trades Rev., vol. 97, no. 2628, July 12, 1918, pp. 34-35. Paper read before the South Midland Branch of the Nat. Assn. of Colliery Managers.

Training Men for the Shipyards. F. Forrest Pease. Am. Mach., vol. 49, no. 3, July 18, 1918, pp. 109-110. The experiences of the Shipping Board and suggestions as to how other industries may profit from them.

Training Men Instead of Stealing Them. Fred H. Colvin. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1035-1039, 12 figs. Account of the training shop for developing skilled mechanics established by the Norton Grinding Co., Worcester, Mass.

Vestibule Schools for the Unskilled. H. E. Miles. Indus. Management, vol. 56, no. 1, July 1918, pp. 10-12. Shows how such schools are organized and gives results from those already in operation.

Turnover

Minimum Turnover in Machine-Shop Labor. Stanley H. Bullard. Iron Age, vol. 102, no. 4, July 25, 1918, pp. 204-206. Labor policy and wage classification plan of the Bullard Machine Tool Co. Results in output and *esprit*.

LIGHTING (ILLUMINATION)

Elements of Illuminating Engineering. Ward Harrison. Elec. Eng., vol. 52, no. 1, July 1918, pp. 37-39. Principles involved in the science of lighting buildings and public highways. (Continuation of serial.)

Artificial Daylight

A Precision Method for Producing Artificial Daylight. I. G. Priest. Physical Rev., vol. 11, no. 6, June 1918, pp. 502-504, 1 fig. Diagrams showing relative energy plotted against wave length of sunlight at the earth's surface and of light from a gas-filled tungsten lamp passed through a quartz plate 0.5 mm. thick between crossed nicol prisms, the path of the light being parallel to the optic axis of the quartz. Abstract of a paper presented before the Am. Phys. Soc.

Factories

How to Plan a Lighting Installation for a Factory. Elec. Rev., vol. 73, no. 2, July 13, 1918, pp. 49-52. Simple rules for contractor or lighting salesman for laying out the lighting system under average conditions, using standard reflectors and Mazda lamps.

Industrial Lighting for Shops. O. L. Johnson. Ry. Rev., vol. 62, no. 25, June 22, 1918, pp. 916-918, 2 figs. Some suggestions and "don'ts" for shop lighting.

Farm Buildings

Wiring of Farm Buildings for Lighting. Elec. Rev., vol. 73, no. 2, July 13, 1918, pp. 67-68, 1 fig. Chart for finding proper wire size for low-voltage lighting plants.

Meat-Packing Plants

Improved Lighting of Meat-Packing Plants. F. H. Bernhard. Elec. Rev., vol. 73, no. 3, July 20, 1918, pp. 87-92, 12 figs.

Textile Mills

Better Lighting of Textile Mills. F. H. Bernhard. Elec. Rev., vol. 72, no. 26, June 29, 1918, pp. 1070-1077, 10 figs. Better lighting to improve quality of product; lighting requirements of textile mills.

See also Electrical Engineering (Lamps).

LUBRICATION

See Air Machinery (Air Compressors); Internal-Combustion Engineering (Lubrication); Machine Tools (Lubrication); Motor-Car Engineering (Lubrication); Railroad Engineering, Steam (Lubrication); Testing and Measurements (Viscosity Measurement).

MACHINE PARTS

Bearings

Notes on Babbitt and Babbitted Bearings. J. L. Jones. Tran. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1395-1401, 5 figs. Results of tests performed at progressively increasing temperatures on bearing bronze and description of a process and a tool claimed to give smoother and more accurate surfaces to bearings than heretofore possible.

Crankshafts

Broken Crankshafts. Maurice M. Clement. Power Plant Eng., vol. 22, no. 14, July 15, 1918, pp. 564-565. Some causes and their prevention.

Gears

On Matsumura's Interchangeable Wheel Teeth (in Japanese). Tsuruzo Matsumura. Jl. of the Soc. M. E., Tokyo, vol. 21, no. 52, June 1918.

Reliable Gears. C. J. Brown. Coal Age, vol. 14, no. 3, July 20, 1918, pp. 99-100. Hardness and toughness for reliability accomplished by heat treatment of steel.

See also Mechanics (Helical Springs); Motor-Car Engineering (Springs).

MACHINE SHOP

Boring-Mill Operation

Time Studies for Rate Setting on Gisholt Boring Mills-I. Dwight V. Merrick. Indus. Management, vol. 56, no. 1, July 1918, pp. 34-41, 11 figs. The preparation of a boring mill for the work to be done. Seventeen tables give the necessary data, each table being devoted to a single operation.

Bulldozer Operation

Essentials of Bulldozer Operations—The V-Blocks. J. V. Hunter. Am. Mach., vol. 49, no. 5, August 1, 1918, pp. 195-199, 18 figs. Examples of operations on this machine.

Coloring, Lacquering and Finishing

Approved Practice in Coloring and Lacquering. James Steelman. Brass World, vol. 14, no. 6, June 1918, pp. 163-167, 9 figs. Oxidizing effects on silver; electric ovens.

Black and Steel Gray Finishes on Brass and Iron. Fred J. Liscomb. Brass World, vol. 14, no. 6, June 1918, pp. 159-161. Some objection to the "Rock Island" formulae; a consideration of the arsenic solution for steel-gray finish; lacquering.

Crankshaft Making

A California Jobbing Shop. Frank A. Stanley. Am. Mach., vol. 49, no. 3, July 18, 1918, pp. 121-123. Laying out, roughing down and finishing crankshafts for gasoline motors.

Die Casting

Die-Casting of Aluminum Bronze. H. Rix and H. Whitaker. Page's Eng. Weekly, vol. 32, no. 708, April 5, 1918, pp. 160-162. Process of die casting and factors affecting the future development of the industry.

Grinding

Cylindrical Grinding. W. D. Adamson. Machy. Market, no. 925, July 26, 1918, p. 21. Classification and description of internal-grinding machines. (Continued.)

Heat-Treating

The Electric Furnace for Heat-Treating. T. F. Baily. Am. Drop Forger, vol. 4, no. 7, July 1918, pp. 257-260, 3 figs. From a paper presented at the convention of the Am. Drop Forge Association.

Indian Shop

New Smith, Forge, Spring Die Sinkers and Drop Forging Shops at Khargpur Works, Bengal-Nagpur Ry. Ry. Gaz., vol. 29, no. 1, July 5, 1918, pp. 18-22. Layout of buildings and equipment.

Pipe (Smokers') Making

The Making of a Smoker's Pipe. J. V. Hunter. Am. Mach., vol. 49, no. 3, July 18, 1918, pp. 93-98, 17 figs. Description of the manufacture of brier pipes.

Square (Gage Makers') Making

Making Accurate Squares for Gagemakers. John Teckeer. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1041-1043, 10 figs. Describes methods by which a gage maker can produce his own squares.

See also Foundry (Welding; Sandblast); Marine Engineering (Welding); Steel and Iron (Heat Treatment).

MACHINE TOOLS

Boxing Machinery

Boxing Machinery to Prevent Damage. Luther D. Burlingame. Indus. Management, vol. 56, no. 1, July 1918, pp. 27-33, 18 figs. Practice of Brown & Sharpe Manufacturing Co. in packing machinery and tools for shipment.

Cost

The Rising Cost of Machine Building. Ludwig W. Schmidt. Am. Mach., vol. 49, no. 5, August 5, 1918, pp. 209-211.

Drills

Cable or Well Drills as Adapted to Blast Hole and Quarry. Eng. & Cement World, vol. 13, no. 2, July 15, 1918, pp. 60-66.

Choosing the Right Rock Drill. John F. Berteling. Mine & Quarry, vol. 10, no. 4, July 1918, pp. 1069-1073. A few instances of actual experience in fitting different types of drilling machines to various kinds of work.

Drill Bits and Drill Steel—Selecting, Forging and Tempering. George H. Gilman. Mine & Quarry, vol. 10, no. 4, July 1918, pp. 1075-1082, 18 figs. Present practice, specifications for straight-carbon hollow drill steel, details of the sharpening shop, and duties of the inspector regarding the tempering of drills.

Properties of Twist-Drills. B. W. Benedict and W. P. Lukens. Western Eng., vol. 9, no. 8, August 1918, p. 319. Conclusions drawn from an investigation of twist drills at the Engineers Experiment Station of the Univ. of Illinois. Abstract from Bul. No. 103 of the Eng. Experiment Station of the Univ. of Illinois.

Foreign Tariffs

Effect of Changes in Foreign Tariffs on the American Machine-Tool Industry. L. W. Schmidt. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1047-1049.

Jigs and Fixtures

Templets, Jigs and Fixtures. Joseph Horner. Engineering, vol. 105, no. 2736, June 7, 1918, pp. 628-632, 50 figs. Fourth of a series, the present describing fixtures and jigs used in the manufacture of a radial drilling machine.

Lubrication

The Lubricating Problem. Raymond Francis Yates. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1039-1040, 3 figs. Points out importance of lubricating machine tools.

Remanufacturing

Remanufacturing Machine Tools. Sibley Jl. of Eng., vol. 32, no. 11, August 1918, pp. 171-173, 4 figs. Offers solution to the problem of redistributing tools and of restoring them to their original condition of operation.

Toolroom

Toolroom Methods in a Pacific Coast Factory. Frank A. Stanley. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1051-1055, 13 figs. Making of a varied line of punches, dies, jigs and fixtures; interesting presswork and tools.

MARINE ENGINEERING

Boilers

Corrosion of Marine Boilers. D. E. Rees. Am. Marine Engr., vol. 13, no. 7, July 1918, pp. 16-17. Suggestions in the care of marine boilers. From a paper read before the Inst. of Marine Engrs.

Cargo Ships

Standard Cargo Ships. Sir George Carter. Int. Mar. Eng., vol. 23, no. 7, July 1918, pp. 407-413, 6 figs. British practice in the design and construction of standard cargo ships. Paper read before the Inst. of Naval Architects, London, March 1918.

Cargo-Vessel Design

Longitudinal Framing and Diagonal Planking. J. R. Oldham. Nautical Gaz., vol. 93, no. 6, August 10, 1918, p. 65, 4 figs. A proposed bulk-cargo-vessel design.

Modern Shipbuilding and Economy in Material. Shipbuilding and Shipping Rec., vol. 11, no. 19, May 9, 1918, pp. 515-516, 3 figs. A series of comparisons between the transverse and longitudinal systems of framing wooden and steel ships. From a paper by J. W. Isherwood before the Soc. of Engrs.

The Relation of Speed to Dimensions in Merchant Ships. Shipbuilding & Shipping Rec., vol. 12, no. 3, July 18, 1918, p. 65. Experimental facts regarding the effects that details of construction of a ship have on speed.

Concrete Ships

Concrete Ship for the U. S. Shipping Board. Nauticus, vol. 1, no. 7, July 13, 1918, pp. 204-208. Specifications and com-

parative weight for a standard concrete ship given by the Emergency Fleet Corporation to the Committee of Commerce, U. S. Senate.

Construction of Concrete Ships for Emergency Fleet Corporation. R. J. Wig. Western Eng., vol. 9, no. 8, August 1918, pp. 306-307. Abstract of special report to Edward N. Hurley, chairman, U. S. Shipping Board, dated April 5, 1918.

Government Attitude on the Concrete Ship. Waldon Fawcett. Int. Mar. Eng., vol. 23, no. 7, July 1918, pp. 381-382.

The Big Concrete Ship Not Unreasonable. J. F. Springer. Int. Mar. Eng., vol. 23, no. 7, July 1918, pp. 383-386. A reply to Professor Everett's article on The Fallacy of Concrete Ship Construction.

Deep-Sea Diving

The Possibilities of Deep-Sea Diving. Robert G. Skerrett. The Rudder, vol. 34, no. 8, August 1918, pp. 370-374. Discusses pressures the human body is capable of withstanding.

Electric Power

Electricity's Part in Building and Navigating of Ships. H. A. Hornor. Elec. Eng., vol. 52, no. 1, July 1918, pp. 15-18. Electrical apparatus used in ships. (Continuation of serial.)

Electric Propulsion

Electrical Ship Propulsion. Am. Marine Engr., vol. 13, no. 7, July 1918, pp. 13-14. Study of the convenience in using an electric plant as a flexible gearing between the power generator and the propeller. From Engineering (London).

Fumigating Apparatus

Fumigating Apparatus for Shipyards and Emigrant Ships. Shipbuilding and Shipping Rec., vol. 12, no. 1, July 4, 1918, pp. 15-16, 1 fig. Apparatus constructed on the principle of the destruction of infection and of vermin by high-pressure dry-saturated steam which insures a temperature of 250 deg. fahr., thus destroying all germs without damaging or even wetting the goods.

Hog Island

Shipbuilding in the United States. Engineer, vol. 125, no. 3261, June 28, 1918, pp. 554-555, 18 figs. A description of the shipbuilding plant at Hog Island.

Propellers

Screw Propellers. D. W. Taylor. Shipbuilding and Shipping Rec., vol. 12, no. 1, July 4, 1918, pp. 35-39, 30 figs. Formulae and set of curves for the determination of the dimensions of screw propellers. (End of serial; previous articles appeared in vol. 10 (July-December 1917), pp. 55, 81, 223, 274, 464 and vol. 11, p. 469.)

Salvage

Deep Water Salvage. The Nautical Gaz., vol. 93, no. 3, July 20, 1918, p. 28, 2 figs. Proposed device for raising vessels from great depths.

Salvage of Merchant Ships. Engineer, vol. 125, no. 3260, June 21, 1918, pp. 532-534, 9 figs. Description of the work of the Salvage Department of the Admiralty.

The Salvage of Deeply Sunken Ships. R. G. Skerrett. Scientific Am., vol. 119, no. 3, July 20, 1918, pp. 43-58. Engineering difficulties in salving a ship and account of some of the reports of the Salvage Department of the British Admiralty.

Seattle

Seattle Shipbuilders Overcome Pioneer Difficulties and Set New Speed Records. Claude A. Osier. Eng. News-Rec., vol. 81, no. 4, July 25, 1918, pp. 160-164, 8 figs. High-speed work in inadequate plant; persistent expediting of material; labor problems; two new machines used.

Ships' Hulls

Oil- and Water-tight Joints in Ships' Hulls. Evers Burtner. Int. Mar. Eng., vol. 23, no. 7, July 1918, pp. 404-406, 24 figs. Effective methods of securing water- and oil-tight joints in ships' structure under different conditions.

Statistics

American Merchant Marine Will Total 5,000,000 Tons in 1920. Edward N. Hurley. Int. Mar. Eng., vol. 23, no. 7, July 1918, pp. 379-381. Address by Chairman of U. S. Shipping Board at Univ. of Notre Dame, June 10, 1918.

Tonnage Measurement

Explanation of the Several Methods of Expressing the Tonnage of Vessels. Sibley Jl. of Eng., vol. 32, no. 11, August 1918, pp. 170-171. Compiled from material supplied by the Chief of the Hull Drafting Department at the Harlan plant of the Bethlehem Shipbuilding Corp.

Power, Speed and Dead Weight Carrying Capacity of Screw Steamers. H. P. Frear. Sibley Jl. of Eng., vol. 32, no. 11, August 1918, pp. 168-170. Treatise of the elementary facts and principles connected with the subject.

Tonnage and Displacement Explained. The Rudder, vol. 34, no. 8, August 1918, pp. 388-391. (Continued from preceding issues.)

Welding, Electric

Electric Welding in Ship Work—A Rivetless Vessel. Times Eng. Supp., no. 525, July 1918, p. 149. Possibilities of extending the electric-welding system used in the building of a rivetless ship recently launched on the south coast of England and built in a shipyard operated by the Inland Waterworks and Docks Section of the Royal Engineers.

Wooden Ships

Revival of Wooden Ships. Nautical Gazette, vol. 93, no. 5, August 3, 1918, p. 52. Comparison between wooden and steel ships.

See also Internal-Combustion Engineering (Diesel Engines; Heavy Oil Engines); Power Generation (Electric Power Applications); Research (Marine Engineering).

MATHEMATICS

Differential Equations

Brief Synopsis of Differential Equations. N. W. Akimoff. Automotive Eng., vol. 3, no. 6, July 1918, pp. 247-250. Preliminary review of differential equations in their application to the study of oscillations.

Contribution to the Study of Oscillation Properties of the Solutions of Linear Differential Equations of the Second Order. R. G. D. Richardson. Am. Jl. of Mathematics, vol. 40, no. 3, July 1918, pp. 283-316.

Interpolation Properties of Orthogonal Sets of Solutions of Differential Equations. O. D. Kellogg. Am. Jl. of Mathematics, vol. 40, no. 3, July 1918, pp. 225-234. Types of boundary conditions and establishment of the property (D). Continued from No. 2. Presented to the Am. Mathematical Soc.

Determinants

P-Way Determinants, with an Application to Transvectants. Lepine Hall Rice. Am. Jl. of Mathematics, vol. 40, no. 3, July 1918, pp. 242-262. Definition of a determinant, formulated to remove the restriction in Cayley's law of multiplication and to set up a new case in Scott's law of multiplication; generalization to P dimensions of Metzler's theorem in two dimensions concerning a determinant, each of whose elements is the product of k factors.

Integration

Directed Integration. H. B. Phillips. Am. Jl. of Mathematics, vol. 40, no. 3, July 1918, pp. 235-241. Manner of directly attaching the algebraic sign to the element of integration, multiple integrals being treated like curvilinear.

On the Numerical Solution of Integral Equations. E. T. Whittaker. Proc. of the Royal Soc., vol. 94, no. A662, June 1, 1918, pp. 367-383. Theoretical solutions of integral equations of the Abel and Poisson types.

Theory of Functions

A Theorem on the Variation of a Function. Paul R. Rider. Bul. of the Am. Mathematical Soc., vol. 24, no. 9, June 1918, pp. 430-431.

On a Certain Functional Equation. Tsuruichi Hayashi. Science Reports of the Tôhoku Imperial University, vol. 7, no. 1, July 1918, pp. 1-32. Study of convex closed curves inscribable and revolvable in a polygon.

On a Certain General Class of Functional Equations. W. Harold Wilson. Am. Jl. of Mathematics, vol. 40, no. 3, July 1918, pp. 263-282. Contribution to systematize a general theory. Read before the Am. Math. Soc.

Theory of Functions (Théorie des fonctions). M. C. de la Vallée Poussin. Académie des Sciences, vol. 166, no. 21, May 27, 1918, pp. 843-846. Analytical investigation of the properties of the derivatives of some forms of trigonometric expressions.

Theory of Numbers

Theory of Numbers (Théorie des nombres). M. G. Humbert. Académie des Sciences, vol. 166, no. 22, June 3, 1918, pp. 865-870. Comment on a similar discussion appearing in the preceding issue.

Volume Measurement

Volume Generated by the Rotation of a Spherical Contour (Sur les volumes engendrés par la rotation d'un contour sphérique). M. A. Buhl. Académie des Sciences, vol. 166, no. 22, June 3, 1918, pp. 896-897. Derivation of the general formula by the method of integral calculus.

MECHANICS

Columns, Critical Loading

Critical Loading of Struts and Structures. W. L. Cowley and H. Levy. Proc. of the Royal Soc., vol. 94, no. A662, June 1, 1918, pp. 405-422, 6 figs. Discussion of the stability of a prismatic homogeneous strut on simple supports, generalization of the equation of three moments, and study of the external loading due to wires in tension attached to a beam in the region of the supports.

Elastic-Strain Analogies

Transmission of Activation in Passive Metals as a Model of the Protoplasmic or Nervous Type of Transmission. Ralph S. Lillie. Science, vol. 48, no. 1229, July 19, 1918, pp. 51-60. Close analogies between the physico-chemical nature of nerve conduction and the electric current and inadequate comparison of nerve action to the transmission of mechanical influences such as elastic strain or vibration and to the propagation of explosive waves.

Helical Springs

Strength of Helical Springs. W. A. Atkinson. Mechanical World, vol. 63, no. 1637, May 17, 1918, pp. 234-235, 3 figs. Explanation of an accompanying table of maximum loads in pounds, and corresponding deflection per coil in inches of helical round steel wire springs.

Pipes, Curved

Stresses in Curved Pipes. J. S. Henzell. Mechanical World, vol. 64, no. 1644, July 5, 1918, p. 4, 2 figs. Analytical study of the effect of internal fluid pressure on curved pies. (To be continued.)

Shafts, Horizontal, Critical Speed

The Lower Critical Speed of Horizontal Shafts (in Japanese). Iwao Oki. Jl. of the Soc. M. E., Tokyo, vol. 21, no. 52, June 1918.

Sphere, Light, Movement in Air

On the Movement of a Light Spherical Ball in Air (Sur le mouvement d'une balle sphérique légère dans l'air). Paul Appell. Journal de Physique, vol. 7, March-April 1917, pp. 49-52. Remarks on Lord Rayleigh's article on the irregular flight of a tennis ball, published in the Messenger of Mathematics, no. 73, 1877.

Steel Columns

Recommended Unit-Stresses in Steel Columns and Struts. Western Eng., vol. 9, no. 8, August 1918, p. 312. Diagram showing stresses recommended for different values of l/r both by the Am. Ry. Eng. Assn. formula and by the formula recommended by a special committee of the Am. Soc. C. E.

See also Engineering Materials (Glass); Power Plants (Piping).

METAL ORES

Crushing Resistance

Crushing Resistance of Various Ores. L. W. Lennox. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1255-1264, 10 figs. Account of tests and summary of results.

Lead

Mineralogy of Ores. H. L. Payne. Min. and Oil Bul., vol. 4, no. 8, July 1918, p. 339. Information concerning the ores of lead: galenite, cerussite, anglesite, crocoite. (Continuation of a serial.)

Mercury

Note on Extraction of Mercury from its Ores by Sodium Sulphide. C. H. Holland. New Zealand Jl. of Science & Technology, vol. 1, no. 3, May 1918, pp. 153-154. Report of experiments and description of method.

Molybdenum

Molybdenite Operations at Climax, Colorado. D. F. Haley. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1183-1188. Geology, mining system and marketing of the deposit.

Pyrites

Pyrite Deposits of Leadville, Colo. H. S. Lee. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1223-1229. Geology, occurrence of the ore, method of mining it and its value in the manufacture of sulphuric acid.

Radium

Radium. Richard B. Moore. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1165-1182. History, disintegration series, ore deposits, metallurgical treatment, methods of ore concentration, supply of ore, substitute for and uses of radium.

Spelter

Spelter Statistics for 1917. W. R. Ingalls. Eng. & Min. Jl., vol. 106, no. 4, July 27, 1918, pp. 176-181.

Sulphur

Recently Recognized Alunite Deposits at Sulphur, Humboldt County, Nevada. I. C. Clark. Eng. & Min. Jl., vol 106, no. 4, July 27, 1918, pp. 159-163, 5 figs.

Tungsten

Molybdenum, Tungsten and Bismuth. Indus. Australian & Min. Standard, vol. 59, nos. 1544 and 1546, June 13 and 27, 1918, pp. 623-624, 688-689; vol. 60, no. 1547, July 4, 1918, pp. 29-30, 1 fig. Treatise on these minerals dealing with the general character, associated metallic minerals and geological features of their ores. (To be continued.)

Tungsten Ore Deposits Near Falcon Lake, Manitoba. Justin S. DeLury. Can. Min. Jl., vol. 39, no. 11, June 1, 1918, pp. 186-188, 6 figs. Map of area and brief description of its geology.

Tungsten Ores in Southern Rhodesia. H. B. Maufe. South African Min. Jl. & Eng. Rec., vol. 27, part 2, no. 1390, p. 61. Abstract from Report No. 4 of the Southern Rhodesia Geological Survey.

Vein Formation

The Mechanics of Vein Formation. S. Taber. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1189-1222, 5 figs. Methods of vein formation.

See also Engineering Materials (Tungsten).

METALLURGY

Baghouses

Baghouses for Zinc Oxide. John F. Cregan, Eng. & Min. Jl., vol. 106, no. 3, July 20, 1918, pp. 126-132, 7 figs. Further improvement and standardization in design essential.

Blast Furnaces

Copper Tuyeres for Blast Furnaces. A. K. Reese. Blast Furnace & Steel Plant, vol. 6, no. 8, August 1918, pp. 329-330, 2 figs. Results obtained with copper tuyeres and considerations on their adoption. Paper read before the British Iron & Steel Inst.

Principal Changes in Blast Furnace Lines. J. G. West. Blast Furnace & Steel Plant, vol. 6, no. 8, August 1918, pp. 323-329, 56 figs. Discussion of theoretical lines and account of the development of the hearths. (Continued.)

Copper Refining, Electrolytic

New Cornelia Copper Company's Plant a Success. R. B. Leach. Min. and Oil Bul., vol. 4, no. 8, July 1918, pp. 315-328, 4 figs. Layout of buildings and description of processes followed by a plant said to produce 80 lb. of pure electrolytic copper per min.

Cyanide Process

Charcoal Precipitation of Gold in Cyanide Solutions. Chem. Eng. & Min. Rev., vol. 10, no. 118, July 1918, pp. 309-310. Comments on a paper describing the Moore-Edmands process, as installed at the Yuannii mine, W. A., published in the issue of November 1917.

Effect of Oxygen Upon the Precipitation of Metals from Cyanide Solutions. T. B. Crowe. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1279-1282. Effect of vacuum precipitation on consumption of cyanide and opposing action of oxygen and hydrogen.

Fine-Grinding Cyanide Plant of Barnes-King Development Co. J. H. McCormick. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1283-1291, 4 figs. Description of the operations in the mine.

Roasting for Amalgamating and Cyaniding Cripple Creek Sulphotelluride Gold Ores. A. L. Bomfield and M. J. Trott. Trans. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1265-1278, 2 figs. Classification of ores, chemical reactions in roasting and rapid methods of analysis for sulphur in ores.

Recent Progress

Notes on Recent Metallurgical Progress. E. P. Mathewson. Eng. & Min. Jl., vol. 106, no. 3, July 20, 1918, pp. 138-145, 3 figs. Impressions received during a journey of observation among the great smelteries of the United States, with practical comments on design and operation.

Rolling Alloy Strips

New Installation for Rolling Alloy Strips. Blast Furnace & Steel Plant, vol. 6, no. 8, August 1918, pp. 819-821. Process of the Nat. Pressed Steel Co., Massillon, Ohio.

Silver-Lead Smeltery

Ideal Layout for Silver-Lead Smeltery. Guy C. Riddell. Eng. & Min. Jl., vol. 106, no. 3, July 20, 1918, pp. 115-122, 3 figs. Details of a plant for a 100- to 3000-ton daily charge.

Slag, Open-Hearth, Basic

Utilization of Basic Open Hearth Slag. Blast Furnace & Steel Plant, vol. 6, no. 8, August 1918, p. 322. Account of the progress of this industry in England. From Jl. Soc. Chem. Industry.

See also Aeronautics (Materials of Construction).

MILITARY ENGINEERING

Ballistics

Internal Ballistics. Engineer, vol. 125, no. 3258, June 7, 1918, p. 490. Abstract of a lecture by Lieut.-Col. A. G. Hadcock delivered at the Royal Inst.

Planetary Ballistics

Planetary Ballistics (De balistica planetaria). Madrid Cientifico, year 25, no. 956, June 5, 1918, pp. 281-283. Mathematical investigation of the range of a projectile in terms of its initial velocity and the angle of projection.

Gun Erosion

Gun Erosion. Engineering, vol. 105, no. 2736, June 7, 1918, p. 640. Discusses H. M. Howe's views on the hardening of the gun bore, reasons for cracking, and suggests a remedy for erosion troubles. Abstract of a paper read by H. C. H. Carpenter before the Inst. of Naval Engrs.

Military Training

Army Engineer School in France Standardizes Work in the Field. Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 3, July 18, 1918, pp. 112-117, 13 figs. Course of training for men recommended for commissions; classes trained in mining, pioneering, bridging, topography, camouflage, sound ranging and interpretation of aerial photographs.

Training Mechanics for Service in Army Field Units. J. V. Hunter. Am. Mach., vol. 49, no. 4, July 25, 1918, pp. 163-167, 13 figs. Methods employed in training drafted men for the needs of the Army.

Torpedoes

Moving Targets and Torpedo Attack. Engineer, vol. 125, no. 3261, June 28, 1918, pp. 561-563, 14 figs. A mathematical consideration.

See also Munitions.

MINES AND MINING

Cementation and Concreting

Cementation in the Illinois Oil Field. M. L. Nebel. Eng. & Min. Jl., vol. 105, no. 24, June 15, 1918, pp. 1080-1082, 1 fig. Use of cement, excluding water, to increase immediate production and probably total extraction, also lower operating costs.

Notes on Shaft Relining With Concrete. G. G. Stonemark. Eng. & Min. Jl., vol. 106, no. 1, July 6, 1918, pp. 8-10. Methods used in two Minnesota shafts.

Cementing

Stripping and Relining a Shaft at Cowdenbeath, Fife. Henry Rowan. Queensland Government Min. Jl., vol. 19, no. 217, June 15, 1918, pp. 266-267. From a paper read before the Min. Inst. of Scotland.

Electrical Operation

Earthing Electrical Services in Mines. Colliery Guardian, vol. 116, no. 3002, July 12, 1918, pp. 70-71. Necessity of a good earth contact; the ideal earth.

The Safe Operation of Power Plant Switchboards. L. Fokes. Colliery Guardian, vol. 116, no. 3001, July 5, 1918, pp. 17 18, 8 figs. Safe methods of handling electricity in mines.

Mine Surveying

The Future Aspect of Mine Surveying. John Proctor. Colliery Guardian, vol. 116, no. 3003, July 19, 1918, pp. 121 122. Influence of magnetic declination, extraneous objects and electricity on surveys; description of methods adopted; necessity for accuracy.

Oil

Methods of Increasing the Recovery from Oil Lands. J. O. Lewis. Automotive Eng., vol. 3, no. 6, July 1918, pp. 274-277. Suggested ways in which it is claimed more crude oil can be obtained from any given oil field. (Concluded.)

Sand Filling

Notes on Sand Filling in Mines. C. H. Greathead. Colliery Guardian, vol. 116, no. 3003, July 19, 1918, p. 125.

Ventilation

Canvas Tubing for Mine Ventilation. Lester D. Frank. Queensland Government Min. Jl., vol. 19, no. 217, June 15, 1918, pp. 249-251, 4 figs. Manner in which canvas tubing is being used in the North Butte Company's mines at Butte, Mont. Abstract from Bul. A. I. M. E., February 1918.

MOTOR-CAR ENGINEERING

British Motors

The Industrial Motor. Motor Traction, vol. 27, no. 696, July 3, 1918, pp. 1-2. The products of the British motor industry reviewed and classified according to their respective uses. (Continuation of serial.)

Electric Vehicles

The Electric Vehicle Committee. Motor Traction, vol. 27, no. 696, July 3, 1918, pp. 14-15. Annual report for the year ended March 31, 1918.

War Time Uses of Industrial Electric Trucks. Elec. Rec., vol. 24, no. 2, August 1918, pp. 57-67. Uses of electric trucks and specifications of the different types.

Electrical Equipment

Ignition, Starting, Generating and Lighting System on Automotive Vehicles. C. L. White. Auto and Tractor Shop, vol. 17, no. 10, July 1918, pp. 240-241, 4 figs. Elementary facts and principles of ignition; connection of batteries; make-and-break ignition systems.

Lighting Generators and Starting Motors for the Automobile. Elec. Rec., vol. 24, no. 2, August 1918, pp. 68-73. Features of modern designs of lighting generators and starting motors and outline of their necessary auxiliary devices.

The Care and Repair of Automobile Starting and Lighting Batteries. Auto and Tractor Shop, vol 17, no. 10, July 1918, pp. 244-246, 3 figs. Remarks and suggestions. (To be continued.)

The Testing of British-Made Magnetos. H. M. Buist. Autocar, vol. 41, no. 1186, July 13, 1918, p. 44. Suggestions resulting from a visit of the author to a number of British magneto factories.

Lubrication

A New Chassis Lubrication System. Automotive Industries, vol. 39, no. 3, July 18, 1918, pp. 95-96, 4 figs. Scheme by which oil is fed to bearings by wicks and quantity fed is regulated by localized compression of the wicks.

Motor Buses

The Industrial Motor. Motor Traction, vol. 27, no. 696, July 3, 1918, pp. 1-2. Capabilities and costs of public-service vehicles. (To be continued.)

Speedometers

Speedometers and How to Care for Them. L. W. Burchinal. Auto and Tractor Shop, vol. 17, no. 10, July 1918, pp. 249-250, 5 figs. Principle of operation of each one of the four different types of speedometers; forms of speedometer cables; method of attaching speedometer sprockets and swivel joint to the front wheel of an automobile.

Springs

The Springs of the Car. F. M Faual. Auto and Tractor Shop, vol. 17, no. 10, July 1918, pp 255-256, 9 figs. History of the introduction of springs in the manufacture of vehicles and review of the principles involved in their use

Tires

A New South African Tire. The Autocar, vol. 40, no. 1184, June 29, 1918, p 651, 1 fig Features of a new casing claimed to be of advantage on deeply rutted roads.

Tractors

Economical Sizes of Tractors. Ernest Goldberger. Power Wagon, vol. 21, no. 165, August 1918, pp 53-54, 2 figs. Record of the performances of tractors in different kinds of work

Soil Resistance and the Tractor. Fred. M. Loomis. Motor Age, vol. 34, no. 3, July 18, 1918, pp. 20-23. Rules to figure drawbar pull and to determine the size of machine needed.

The Oil-Burning Tractor Engine. H. T. Sward. Automotive Eng., vol. 3, no. 6, July 1918, pp. 265-266. Development and special requirements of the oil-burning tractor. Paper read before the joint meeting of the Chicago Section of the Soc. of Automotive Engrs. and the Nat. Gas. Eng. Assn. in Chicago, Ill.

Trucks

Applying Engineering Principles in the Design of Trucks. Norman Litchfield. Elec. Ry. Jl., vol. 52, no. 3, July 20, 1918, pp. 109-111, 2 figs. Eight points to consider; the calculation of the stresses.

Chassis Design of Class B Trucks. Cornelius T. Myers. Power Wagon, vol. 21, no. 165, August 1918, pp. 41-44, 2 figs. Account of the specifications and details of design adopted at the Quartermaster General's Office.

Measuring Motor Truck Ability. Francis W. Davis. Power Wagon, vol. 21, no. 165, August 1918, pp. 26-28. Suggested technical method for determining the hill-climbing ability of a motor truck.

Motor Trucks Build Roads. Good Roads, vol. 16, no. 5, August 3, 1918, pp. 44-45. Machines utilized to haul graders in various localities.

See also Internal-Combustion Engineering (Cylinder Walls).

MUNITIONS

Anti-Aircraft Guns

The Three-Inch Anti-Aircraft Gun, Model 1918. Am. Mach., vol. 49, no. 5, August 1, 1918, pp. 185-190, 5 figs.

Canadian Shell Plant

Canadian National Steel Plant. W. F. Sutherland. Can. Machy., vol. 20, no. 4, July 25, 1918, pp. 75-81. Illustrated article describing the steel plant operated by the Imperial Munitions Board for the British Government.

Chemistry and Metallurgy

The Chemist and Metallurgist in the Munitions Industry. F. E. Gardiner. Can. Machy., vol. 20, no. 4, July 25, 1918, pp. 98-103. Work of the chemist and of the metallurgist in munition factories.

French Field Gun

The Development of the French 75-mm. Field Gun. J. A. Lucas. Am. Mach., vol. 49, no. 4, July 25, 1918, pp. 149-152, 11 figs. The invention, construction and operation during the years of its use.

Hand Grenades

Some Types of Modern Hand Grenades. Rudolph C Lang. Am. Mach., vol. 49, no. 4, July 25, 1918, pp. 139-143, 11 figs. A history of the hand grenade and a description of various types now in use.

Rapid-Fire Guns

The Madsen Gun. Engineer, vol. 125, no. 3258, June 7, 1918, pp. 495-498, 6 figs. Details of the new automatic small-arm which depends for its action on the recoil of the barrel.

Shell Production

Efficient Appliances for Economic Shell Production. J. H. Rodgers. Can. Machy., vol. 20, no. 4, July 25, 1918 pp. 104-108, 8 figs. Illustrations indicating a number of accessories that have been instrumental in the manufacture of the various shells.

Great New Jersey Shell-Loading Plant. Committee on Public Information. Am. Mach., vol 49, no 3, July 18, 1918, pp. 125-130, 8 figs Description of a plant turning out 52,000 loaded shells per day.

How Dummy Iron Shells Are Molded and Cast. H. Cole Estep. Foundry, vol. 46, no. 312, August 1918, pp. 347-350, 6 figs. Two-part flask employed with most of mold in cope; special gating arrangements necessary.

Specifications for Semisteel Projectiles. Foundry, vol 46, no. 312, August 1918, pp. 345-346. Refers to cast semi-steel projectiles, experiments upon which have proven satisfactory enough to warrant ordering 500,000.

See also Air Machinery (Shell Plant).

PHYSICS

Acoustics

The Influence of Amplitude and of Electromagnetic Driving on the Frequency of Tuning Forks. D. C. Miller. Physical Rev., vol. 11, no. 6, June 1918, pp. 497-498, 2 figs. Results of an investigation of the frequency of tuning forks conducted with the Koenig Clock-Fork Abstract of paper presented before the Am. Phys. Soc.

Electricity

On the Formation of Negatively Electrified Rain Drops. F. Sanford. Physical Rev., vol. 11, no. 6, June 1918, pp. 445-448, 1 fig. Negatively electrified drops may be blown from positively electrified drops by a wind which regularly gives off positive charges to water.

The Air-Damped Vibrating System: Theoretical Calibration of the Condenser Transmitter I. B. Crandall. Physical Rev., vol. 11, no. 6, June 1918, pp. 449-460, 8 figs. Mechanical theory of the Wente's condenser transmitter; mechanism of air-dampening and formulae for practical calculations. Paper read before Am. Phys. Soc.

The New Thermo-Electric Effect (Le nouvel effet thermo-électrique). M. Carl Benedicks. Revue de Métallurgie, year 15, no. 3, May-June 1918, pp. 329-332, 3 figs. Outline of experiments demonstrating that differences in temperature establish an electric current in a homogeneous metallic circuit.

Expansion of Metals

Expansion of Metals by Heat. John Roger. Western Eng., vol. 9, no. 8, August 1918, p. 316. Table of coefficients of expansion of metals by equal units of temperature and by equal units of energy, and of other physical properties of these substances.

Ions

On the Possibility of Tone Production by Rotary and Stationary Spark Gaps (in Japanese). H. Yagi. Denki Gakkwai Zasshi, no. 353, January 19218, pp. 105-131.

Liquids

Why Water Overfills a Tumbler. Will H. Coghill and Carl O. Anderson. Scientific Am. Supp., vol. 86, no. 2221, July 27, 1918, pp. 52-53, 3 figs. Study of flotation in its connection with the metal-mining industry.

Luminescence

The Photo-Luminescence and Katho-Luminescence of Calcite. E. L. Nichols, H. L. Howes and D. T. Wilber. Physical Rev., vol. 11, no. 6, June 1918, pp. 485-486. Experiments showing that calcites of the Franklin Furnace variety when subjected to kathode bombardment exhibit phosphorescence of the type hitherto supposed to be peculiar to the uranyl salts. Abstract of a paper presented before Am. Phys. Soc.

Meteorology

Cooling of the Lower Regions of the Atmosphere During the Night. (Sur le refroidissement nocturne des couches, basses de l'atmosphère). Henri Perrotin. L'Aérophile, year 26, no. 9210, May 15, 1918, p. 136. Calculation of the radiation coefficients of the atmosphere at different levels from measured temperature values.

On the Times of Sudden Commencement of Magnetic Storms. S. Chapman. Phys. Soc. of Lond., vol. 30, part 4, June 15, 1918, pp. 205-214 Discussion of the question as to how far magnetic storms commence simultaneously at different parts of the earth, based on the data collected by Bauer for 15 magnetic storms.

Optics

A Theory of Color Vision and the Selective Action of the Eye. R. A. Houston. Scientific Am. Supp., vol. 86, no. 2223, August 10, 1918, pp. 92-93, 10 figs. A non-mathematical account of a theory described in the Proc. Royal Soc., A92, p. 424, 1916. From Science Progress.

Absorbing Power of the Earth's Atmosphere (Contribution a l'étude du pouvoir absorvant de l'atmosphère terrestre). M. A. Boutaric. Annales de Physique, vol. 9, March-April 1918, pp. 113-203, 28 figs. Beginning of an extensive report of observations on the light-absorbing power of the atmosphere and a study of its bearing on the proportion of polarized light diffused by the sky.

Discussion on Visible and Invisible Rays (in Japanese). Denki Gakkwai Zasshi, no. 359, June 30, 1918. Paper read before the meeting of Kwansai Local Section.

Limit of Sensibility of the Eye and Minimum Value of Radiant Energy Which Can Be Perceived Visually (La limite de sensibilité de l'oeil et le minimum de puissance perceptible visuellement). H. Buisson. Journal de Physique, vol. 7, March-April 1917, pp. 68-74. Account of the methods followed by Langley, Drude, Russell and Reeves for evaluating the least mechanical power which can be perceived visually.

On Tracing Rays Through an Optical System. T. Smith. Phys. Soc. of Lond., vol. 30, part 4. June 15, 1918, pp. 221-233, 1 fig. Modification of the formulae for rays in an axial plane published by the author in Proc. Phys. Soc., vol. 27, p. 502, and outline of method followed in calculations relating to the transverse focal lines.

Photograph of an Aurora Model. C. C. Trowbridge. Physical Rev., vol. 11, no. 6, June 1918, pp. 482-483. Description of photographs of a large model of the aurora constructed to study the optical effects of perspective. Abstract of a paper presented before the Am. Phys. Soc.

The Law of Symmetry of the Visibility Function. I. G. Priest. Physical Rev., vol. 11, no. 6, June 1918, pp. 498-502, 1 fig. Deductions from an attached diagram showing the relative visibility of radiant power plotted against wave-length as abscissae. Abstract of a paper presented before the Am. Phys. Soc.

Transparency of Certain Carbon Compounds to Waves of Great Length. H. P. Hollnagel. Physical Rev., vol. 11, no. 6, June 1918, p. 505. Transparency of quartz, benzene, carbon bisulphide and other substances to residual rays of rock salt ($h = 52\ \mu$). Abstract of Am. Phys. Soc. paper.

Visible and Invisible Rays (in Japanese). M. Kimura. Denki Gakkwai Zasshi, no. 254, January 1918, pp. 87-97.

Oscillatory Phenomena

An Harmonic Synthesizer Having Components of Incommensurable Period and Any Desired Decrement. W. J. Raymond. Physical Rev., vol. 11, no. 6, June 1918, pp. 479-481. Apparatus constructed by the mechanician of the Department of Physics of the Univ. of California which serves to draw continuous curves showing graphically the characteristics of complex harmonic motions. Abstract from paper presented before the Am. Phys. Soc.

Variation of Velocity of Waves Due to Motion of the Source. D. Alter. Physical Rev., vol. 11, no. 6, June 1918, pp. 481-482. Generalization of the mathematical theory which asserts that the velocity of sound depends upon the velocity of the source as well as upon the kind of medium of propagation of waves. Abstract of paper presented before the Am. Phys. Soc.

Precipitation

Electrostatic Precipitation. O. H. Eschholz. Tran. Am. Inst. Min. Engrs., no. 140, August 1918, pp. 1293-1306, 11 figs. Present extension of the electrostatic process of fume precipitation; essential features of this system.

Recent Progress

Notes on Recent Progress in Physics (Quelques récents progrès de la Physique). Leon Bloch. Revue Générale des Sciences, year 20, no. 7, April 15, 1918, pp. 198-208. Résumé of recent researches in advanced laboratory work.

Solutions

A Method for the Quantitative Study of Gases in Metals. H. M. Ryder. Physical Rev., vol. 11, no. 6, June 1918, p. 486. Abstract of paper presented before the Am. Phys. Soc.

Solutions of Gases in Liquids (Les solutions des gaz dans les liquids). M. Felix Michaud. Annales de Physique, vol. 9, March-April 1918, pp. 203-232. Beginning of a proposed thorough revision of the theory of gas solutions.

Spectrum

Methyl-Violet as a Red-Sensitiser of the Photographic Plate. Usuburo Yoshida.

Memoirs of the College of Science, Kyoto Imp. Univ., vol. 3, no. 3, April 1918, pp. 69-71, 4 figs. Account of experiments.

The Effect of an Electric Field on the Spectrum Lines of Helium. T. Takamine and N. Kokubu. Memoirs of the College of Science, Kyoto Imp. Univ., vol. 3, no. 3, April 1918, pp. 81-92, 10 figs. Results obtained from investigations relating mainly to the more refrangible lines of helium. (Continued.)

The Reversal of Spectrum Lines Produced by a Spark Under Water. Toshikazu Mashimo. Memoirs of the College of Science, Kyoto Imp. Univ., vol. 3, no. 3, April 1918, pp. 73-79, 1 fig. Result of experiments performed with the view of following the investigations of Konen, Lockyer, Hale and Finger regarding the reversal of lines in the different regions of the spectrum.

Wave-Lengths of the Tungsten X-Ray Spectrum. Elmer Dershem. Physical Rev., vol. 11, no. 6, June 1918, pp. 461-476, 6 figs. Resolving power of a crystal used as a diffraction grating for X-rays; methods of applying the theories concerning resolving power, description of apparatus used in securing the X-ray spectrum; tabulation of experimental results; theoretical considerations.

Structure of Matter

Atomic and Molecular Numbers. Herbert Stanley Allen. Jl. of the Chem. Soc., vols. 113 and 114, no. 667, May 1918, pp. 389-396. Present value of the atomic weight in face of the recent investigations in connection with radioactive elements.

Note on the Weiss Molecular Field in Ferromagnetic Substances. Kôtarô Honda. Science Reports of the Tôhoku Imperial Univ., vol. 7, no. 1, July 1918, pp. 53-58. Comments on Weiss' assumption that if a ferromagnetic substance undergoes the action of an external field, each molecule is in addition subjected to the action of a large field in the direction of the external field.

On the Relation Between the K X-Ray Series and the Atomic Numbers of the Chemical Elements. W. Duane and Kang-Fuh Hu. Physical Rev., vol. 11, no. 6, June 1918, pp. 488-489. Result of measurements of critical absorption frequencies from manganese ($N = 25$) to cerium ($N = 38$), all measured with the same apparatus. Abstract of a paper presented before the Am. Phys. Soc.

Radiation and the Electron. R. A. Millikan. Scientific Am. Supp., vol. 86, no. 2221, July 27, 1918, pp. 60-61, 2 figs. Suggestions for solving the problem of the transmission of light through interstellar space. Article presented at the meeting of the Section of Physics and Chemistry of the Franklin Institute. (To be continued.)

The Electromagnetic Inertia of the Lorentz Electron. G. A. Schott. Proc. of the Roy. Soc., vol. 94, no. A662, June 1, 1918, pp. 422-436. Remarks on G. W. Waker's paper on The Effective Inertia of Electrified Systems Moving with High Speed, in Proc. Roy Soc., A, vol. 93, p. 448, 1917.

The Entropy of a Metal. H. S. Allen. Phys. Soc. of Lond., vol. 30, part 4, June 15, 1918, pp. 215-220, 1 fig. Discussion of the hypotheses assumed in the theory of Ratnowsky and examination of the latter's expression for the entropy of one gram-atom of a substance in the solid state in view of the values obtained by Lewis and Gibson.

The Resonance and Ionization Potentials for Electrons in Thallium Vapor. P. D. Foote and F. L. Mohler. Physical Rev., vol. 11, no. 6, June 1918, pp. 486-487. Account of experiments and interpretation of results obtained. Abstract of paper presented before the Am. Phys. Soc.

POWER GENERATION AND SELECTION

Canada

Availability of Energy for Power and Heat. J. Blizard. Jl. Eng. Inst. of Can., vol. 1, no. 3, July 1918, pp. 112-115. Outline of the sources of energy supply in Canada and of the requirements they meet.

Electric-Power Applications

Application of Electricity in the Modern Navy in the World (in Japanese). T. Minohara. Denki Gakkwai Zasshi, no. 356, March 31, 1918.

Electric Plant at a Canadian Smelting Works. Engineer, vol. 126, no. 3263, July 12, 1918, pp. 24-26, 2 figs. Description of an hydraulic and a steam plant.

Electric Power Supply in the Future. Engineer, vol. 125, no. 3258, June 7, 1918, pp. 498-499. Report of the Committee appointed by the Board of Trade to consider steps to be taken to insure an adequate supply of electric power for all classes of consumers.

Electrically Operated Quarry and Rock Crushing Plant in Chicago. Elec. Rev., vol. 72, no. 26, June 29, 1918, pp. 1067-1069, 7 figs. Electric power applied to drills, haulage, crushers and screens.

Electricity in Agriculture. Elec. Times, vol. 54, no. 1394, July 4, 1918, pp. 19-20, 3 figs. Some notes on electric plowing in France.

Electricity in Coal-Mining Operations. Frank Huskinson. Elec. Rev., vol. 73, no. 1, July 6, 1918, pp. 1-4, 9 figs. Factors governing selection of electrical equipment; comparisons of alternating and direct current; advantages of central-station service.

Motor Drive in Newburgh Shipyard. W. H. Easton. Elec. World, vol. 72, no. 4, July 27, 1918, pp. 160-161, 6 figs. Standard types chosen to insure prompt delivery; individual motor drive selected for speeding output; foolproof equipment permits use of unskilled labor.

Motor Drive in Paper and Pulp Mills. C. E. Clewell. Elec. World, vol. 72, no. 4, July 27, 1918, pp. 152-154, 5 figs. Important applications, particularly beaters and grinders; variations on power requirements; examples of group and individual drive. First of a series.

Opportunities for Central-Station Power in the Oil Fields. L. E. Mohrhardt. Elec. Rev., vol. 73, no. 1, July 6, 1918, pp. 7-11, 7 figs. Application of electric power to the various operations involved and data on horsepower requirements.

See also Forging (Electric Power); Hydraulics (Hydroelectric Plants); Marine Engineering (Electric Power).

POWER PLANTS

Ash Conveyors

Economic Handling of Ashes. Reginald Trautschold. Indus. Management, vol. 56, no. 1, July 1918, pp. 17-20, 4 figs. Suction and steam jet conveyors, bucket carriers, and ash cars. Description of latest developments in ash-handling apparatus and approximate handling cost per ton.

Suction Conveyors for Ashes. R. Trautschold. Compressed Air Mag., vol. 23, no. 8, August 1918, pp. 8843-8845. Mechanical method of accomplishing the ash-handling task. From Indus. Management.

Automatic Stokers

Modern Plant of Paris Medicine Co. Power Plant Eng., vol. 22, no. 13, July 1, 1918, pp. 519-523, 7 figs. Illustrated description of a 100-kw. plant having automatic stokers.

Boiler House

Boiler Settings—Multiple Retort Underfeed Stokers. Charles H. Bromley. Power, vol. 48, no. 4, July 23, 1918, pp. 112-117, 9 figs. The latest and best practice in boiler settings for the multiple retort underfeed stoker. The problem of burning high-volatile and high-ash coals.

Improving Boiler-room Operation. J. L. Kentish-Rankin. Elec. Rev., vol. 72, no. 24, June 15, 1918, pp. 986-989. Bettering performance by standard improved methods and indicating instruments.

The Maintenance of Economy in the Boiler House. D. Wilson. Elecn., vol. 81, no. 9, June 28, 1918, pp. 169-171. The importance of regular and detailed records. The transmission of heat. The sampling and testing of coal with a view to accuracy. Routine desirable in regard to the control of flue gases and combustible in ashes.

Chimneys

Calculations of Sheets for Tapered Stack. John A. Cole. The Boiler Maker, vol. 17, no. 7, July 1918, pp. 187-189, 2 figs. Arrangement of forms for recording calculations to order and lay out cone sheets for tapered portion of stack.

Classification

Power Plant Classification. A. P. Connor. Power Plant Eng., vol. 22, no. 14, July 15, 1918, pp. 566-568. Questionnaire of the Fuel Administration on power-plant equipment and operation. How to fill it out. The Administration's requirements.

Coal Handling

Problems in Coal Handling. W. B. Woodhouse. Elecn., vol. 81, no. 9, June 28, 1918, pp. 162-165, 4 figs. Variations in supply and demand; data regarding quantities for a 100,000-kw. plant; ground necessary for sidings; methods of handling coal and ashes.

Isolated Plants

Isolated Service for Economy. Power Plant Eng., vol. 22, no. 14, July 15, 1918, pp. 559-564, 8 figs. Description of the new condensing turbine plant of the Burroughs Adding Machine Co. at Detroit.

Piping

Determining the Heat Given Off by Engine and Power Piping. E. V. Hill and W. J. Mauer. Heat. & Vent. Mag., vol. 15, no. 7, July 1918, pp. 18-24, 9 figs. Data and results of tests made by the Ventilation Division of the Health Department of the City of Chicago.

Steam Pipe Explosions. Edward Ingham. Colliery Guardian, vol. 115, no. 3000, June 28, 1918, p. 1297, 4 figs. A theoretical investigation of the means for reducing steam-pipe explosions.

Underground Pipe Mains—Material, Depreciation, Sizes for Steam and Water. Charles L. Hubbard. Power, vol. 48, no. 3, July 16, 1918, pp. 80-83. Formulæ and tables for calculating pipe sizes, etc.

Steam Hydroelectric Plant

Galt Waterworks. W. F. Sutherland. Power House, vol. 11, no. 7, July 1918, pp. 195-197. Combined steam and hydroelectric pumping station on the Grand River south of the city of Galt.

See also Electrical Engineering (Electrolysis); Steam Engineering (Steam Traps).

PRODUCER GAS AND GAS PRODUCERS

"Gasteam" Plant at Ford City, Ontario. Power, vol. 48, no. 6, August 6, 1918, pp. 187-193, 13 figs. A combination alternating- and direct-current plant employing "Gasteam" engines; boiler feedwater to recover waste heat from gas-engine cylinder jackets; gas producer plant and its operating methods.

Generation of Suction Gas for Gas Engines. Chem. Eng. and Min. Rev., vol. 10, no. 118, July 1918, pp. 305-306. Results of an investigation made into the working conditions of two suction-gas units at a Bendigo mine, the engines of which developed the required horsepower when connected with charcoal generators, but were found to be deficient in power on being supplied from wood generators.

Practical Operation of a Producer-Gas Power Plant. Francisco R. Ycasimo and Felix V. Valencia. Philippine Jl. of Science, May 1918, vol. 13, no. 3, pp. 99-131, 9 figs. Discussion of tests on Philippine fuels and description of the suction producer gas plant in the power house of the Bureau of Science, Manila.

PUMPS

Air Lift

Irrigating Florida Fruit by the Air Lift System. John Oliphant. Mine & Quarry, vol. 10, no. 47, July 1918, pp. 1064-1065.

Centrifugal Pumps

Modifying Centrifugal Pumps for Direct Motor Connection. B. B. Jackson. Eng. & Cement World, vol. 13, no. 2, July 15, 1918, pp. 70-73, 1 fig. Article explaining a given diagram of the characteristics of a 7-in. medium-head centrifugal pump when operated at five different speeds.

Piston and Plunger Pumps

Lift and Force Pumps. J. H. Perry. Domestic Eng., vol. 84, no. 6, August 10, 1918, pp. 144-196, 5 figs. Design, construction and operation of pumps of the piston and plunger types.

Rotary Feed Pumps

The Weir Turbine-Driven Rotary Feed Pump. Shipbuilding and Shipping Rec., vol. 11, no. 25, June 20, 1918, pp. 683-684, 2 figs.

RAILROAD ENGINEERING, ELECTRIC

Armatures

Some Notes on Maintenance of Armatures. R. H. Parsons. Elec. Traction, vol. 14, no. 8, June 1918, pp. 330-333, 11 figs. Practical suggestions on the care of armatures on electric railways.

Braking, Regenerative

Regenerative Electric Braking on Locomotives of the C., M. & St. P. Ry. W. F. Coors. Ry. Rev., vol. 62, no. 24, June 15, 1918, pp. 867-869, 1 fig. Simplified wiring diagram of the direct-current regenerative braking scheme.

Circuit Breaker

High Speed Circuit Breaker Prevents Flash-over on Milwaukee Electrification. Elec. Ry. Jl., vol. 52, no. 4, July 27, 1918, pp. 154-156, 6 figs. Description of function and operation of a circuit breaker used by the Chicago, Milwaukee & St. Paul Ry., and said to avoid the energy waste resulting from the use of a permanent resistance.

Electrification

Electrification of the Philadelphia Chestnut Hill Section, Pa. R. R. Ry. Gaz., vol. 28, no. 26, June 28, 1918, pp. 756-759. Particulars relating to the electrification of a suburban line.

The Electrification of the Railroads of America (Un mot sur l'électrification des grands chemins de fer aux Etats-Unis d'Amerique). J. Cartier. Revue Générale de l'Electricité, vol. 3, no. 26, June 29, 1918, pp. 913-918. Account of the system of operation in use by the electrified roads of America and study of the reasons which decided in favor of their electrification.

Freight Handling

Freight Handling on the South Shore Lines. Elec. Traction, vol. 14, no. 8, June 1918, pp. 317-321, 4 figs. Features of single-phase electric railway service between Chicago and South Bend, covering the Calumet industrial district.

Italian State Railways

Italian State Railways. Elec. Ry. & Tramway Jl., vol. 38, no. 924, June 14, 1918, pp. 219-220, 2 figs. Polyphase high-speed locomotives 2-C-2, group E 332, recently put into use by the Ateliers de Construction di Oerlikon.

Overhead and Track Work

A Graphical Method of Solving D. C. Track-Circuit Problems. H. M. Proud. Ry. Engr., vol. 39, no. 462, July 1918, pp. 141-145, 5 figs. Attempt to shorten calculations involved in the use of elaborate mathematical formulæ by using graphs in the solution of track problems. Paper presented before the Inst. of Ry. Signal Engrs. (To be continued.)

Electric Railway Construction on the Detroit Superior Bridge. Elec. Ry. Jl., vol. 52, no. 4, July 27, 1918, pp. 145-146, 10 figs. Description of the overhead and track work.

The Maximum Regulating Resistance and Maximum Shunt Resistance of Track Circuits. W. J. Thorrowgood. Ry. Engr., vol. 39, no. 462, July 1918, pp. 140-141. Discussion of an original article published in the issues of May and June, 1918. Paper read before the Inst. of Ry. Signal Engrs.

Passenger Handling

Electric Railway Construction on the Detroit-Superior Bridge. Elec. Ry. Jl., vol. 52, no. 4, July 27, 1918, pp. 145-146, 3 figs. Track, power-supply system and provision for handling passengers on the concrete and steel bridge across the Cuyahoga River at Cleveland, Ohio.

Rail Joints

When Is a Rail Joint Well Bonded? G. H. McKelway. Elec. Ry. Jl., vol. 52, no. 3, July 20, 1918, pp. 111-112, 2 figs. The difference in the conductance of a bonded joint and that of the bond.

RAILROAD ENGINEERING, STEAM

Air Brakes

A 100-Car Test of the Automatic Straight Air Brake. Ry. Age, vol. 65, no. 4, July 26, 1918, pp. 173-176, 4 figs. Runs on Virginian Railway with 100 A. S. A. and combinations of 50 A. S. A. and 50 Westinghouse brakes.

Maintenance of Freight Brakes. T. H. Goodnow. Railroad Herald, vol. 22, no. 8, July 1918, pp. 170-171. Remarks made at a meeting of the Car Foreman's Assn. of Chicago.

Car Axles

Mine Car Axles. B. P. Lieberman. Coal Age, vol. 14, no. 5, August 1, 1918, pp. 219-222, 5 figs. The suitability of iron and steel car axles; improvement of a steel axle of proper analysis by mechanical and heat treatment.

Cross Ties

Standard Specifications for Cross Ties. Ry. Maintenance Engr., vol. 14, no. 8, August 1918, pp. 273-274. Specifications adopted by the Central Advisory Purchasing Committee of the Railroad Administration.

Feedwater Heaters

Feedwater Heaters. J. Snowden Bell. Ry. Rev., vol. 63, no. 1, July 6, 1918, pp. 14-16, 3 figs. Basic principles of construction of feedwater heaters for locomotives. Read before the Am. Master Mechanics' Assn.

Government Control

Railways, Waterways and Highways. Edward A. Bradford. Ry. Rev., vol. 62, no. 26, June 29, 1918, pp. 935-938, 4 figs. Discussion of the present conditions of Government control in the coöperation of waterways, railways and highways.

Locomotive Design

First of the U. S. Standard Locomotives Completed. Ry. Age, vol. 65, no. 3, July 19, 1918, pp. 131-133, 5 figs. Details and description of light Mikado type built by Baldwin Locomotive Works.

Methods of Valve Setting for Walschaert Gear as Used by Am. Loco. Co. J. J. Jones. Loco., vol. 9, no. 2, August 1918, pp. 385-388, 4 figs. Regulations of the Am. Loco. Co.

Mikado Type of Locomotive for United States Government. Ry. Rev., vol. 63, no. 3, July 20, 1918, pp. 87-88, 1 fig. Description of design said to fairly represent the best of conservative thought in American locomotive design.

Modern Locomotive Engine Design and Construction. M. I. and J. T. H. Ry. Engr., vol. 39, no. 462, July 1918, pp. 131-135, 3 figs. Feedwater supply; locomotive feedwater heating systems. (Continuation of a serial.)

New Consolidation Locomotives and Excursion Cars on the Victorian Railways. Engineer, vol. 126, no. 3262, July 5, 1918, pp. 15-16, 5 figs.

Pacific and Mikado Type Locomotives. C., B. & Q. R. R. Ry. Rev., vol. 63, no. 1, July 6, 1918, pp. 1-5, 8 figs. Description of four types.

Recent Advances in Locomotive Efficiency. Paris, Lyons & Mediterranean Ry. Charles R. King. Ry. Rev., vol. 62, no. 24, June 15, 1918, pp. 851-855, 7 figs. The return to the use of compound locomotives with superheated steam after discovery that with improvements in design the superheater compounds are 35 per cent more efficient than the simples.

Locomotive Fuel

Anthracite Silt as a Locomotive Fuel. Ry. Rev., vol. 62, no. 24, June 15, 1918, pp. 857-860, 4 figs. Experiments made to adapt the silt mixture to locomotive use and the methods of preparation.

Lubrication

Coal Production and Lubrication. Reginald Trautschold. Coal Age, vol. 14, no. 4, July 25, 1918, pp. 175-176. Importance of lubrication of mine cars.

Railroad Operation

The Bearing of Malaria on Railroad Operation. H. W. Van Hovenberg. Ry. Age, vol. 65, no. 1, July 5, 1918, 2 figs. Descriptions of benefits to a road from a campaign to eliminate this sickness.

Roadbeds

Concrete Roadbed on Northern Pacific Ry. Eng. & Contracting, vol. 50, no. 3, July 17, 1918, pp. 55-56, 1 fig. Description of an experimental concrete roadbed with detail of construction.

Oil and Concrete-Reinforced Concrete in Railway Work. Ry. Age., vol. 39, no. 462, July 1918, pp. 135-137. Conditions under which oil may affect concrete. (Continuation of serial.)

Shocks in Trains

Shocks in Long Passenger Trains. R. Burges. Railroad Herald, vol. 22, no. 8, July 1918, pp. 172-175. Study of the factors that result in shocks. Review of a paper presented before the Southern and Southwestern Ry. Club.

Shops and Terminals

Buffalo Division Engine Terminals, Lehigh Valley R. R. Ry. Rev., vol. 62, no. 25, June 22, 1918, pp. 895-903, 25 figs. Modernizing the entire Buffalo division. An illustrated description of the important features.

Chilean Railroad Shops of American Design. Walter W. Nowak. Iron Age, vol. 102, no. 3, July 18, 1918, pp. 131-135, 3 figs. Plans won the $20,000 first prize from European engineers. A description of the shops.

New Shops and Engine Terminals, Buffalo, Rochester & Pittsburgh Ry. Ry. Rev., vol. 62, no. 25, June 22, 1918, pp. 907-911, 12 figs. Description of improved engine terminals and shop facilities, features of which are laid out for the requirements of Mallet compounds.

New York Central Opens Cleveland Freight Terminal. Ry. Age, vol. 65, no. 3, July 19, 1918, pp. 117-133, 11 figs. Description of the four-million dollar project.

Signal System

Position-Light Signals on Pennsylvania Railroad. Ry. Age, vol. 65, no. 4, July 26, 1918, pp. 177-178, 1 fig. The extension of the use of this type, its simplified aspects and reduction in costs of maintenance.

Train Operation by Signal Indication. Henry M. Sperry. Ry. Rev., vol. 63, no. 1, July 6, 1918, pp. 9-14, 6 figs. Features of the automatic block signal installation on the Erie from New York to Chicago of interest from a train-operation standpoint.

Train Operation by Signal Indication on the Erie. Henry M. Sperry. Ry. Age, vol. 65, no. 1, July 5, 1918, pp. 5-10, 6 figs. Some forms of train orders eliminated by use of power-operated train-order signals.

Stores

Railway Stores Methods and Problems. W. H. Jarvis. Ry. Gaz., vol. 28, no. 26, June 28, 1918, pp. 753-754; vol. 29, no. 1, July 5, 1918, pp. 9-12. Waste paper; tenders for scrap material; inspection of materials; standard patterns; standardization of materials. (Continuation of serial.)

Superheating

Installation and Maintenance of Superheater Dampers. Ry. Rev., vol. 62, no. 24, June 15, 1918, pp. 886-889, 6 figs. Adapted from Bul. No. 3 by the Locomotive Superheater Co.

Superheaters on Small Locomotives. Railroad Herald, vol. 22, no. 8, July 1918, p. 171. Dimensions of small locomotives built with superheaters by the Vulcan Iron Works, Wilkes-Barre, Pa.

Water Tanks

Creosoted Water Tanks. C. R. Knowles. Ry. Maintenance Engr., vol. 14, no. 8, August 1918, pp. 272-273.

See also Hoisting and Conveying (Loco Tractor).

REFRACTORIES

Silica Brick in Open-Hearth Furnace Roofs. Iron Age, vol. 102, no. 5, August 1, 1918, pp. 270-272. Deterioration as observed by French authorities; role of iron oxide and lime in their manufacture; composition after use in roofs. Translation abstracts made by E. C. Buck.

REFRIGERATION

Ammonia Solubility

The Solubility of Ammonia. M. J. Eichhorn. Ice & Refrigeration, vol. 55, no. 2, August 1, 1918, pp. 41-47, 6 figs. Formulae, tables, existing scientific data and review of researches concerning ammonia solutions in water.

Refrigeration, Electrical

The Opportunity of Electrical Refrigeration. H. N. Sessions. Jl. of Elec., vol. 41, no. 3, August 1, 1918, pp. 104-107. Possibilities of extension of electrical refrigeration.

RESEARCH

Industrial

Coöperation in Industrial Research. Iron Age, vol. 102, no. 3, July 18, 1918, pp. 140-144. A report of the topical discussion at the meeting of the Am. Soc. for Testing Materials, Atlantic City.

Organization of Industrial Research. Arthur D. Little. Eng. & Contracting, vol. 50, no. 4, July 24, 1918, pp. 90-91. New aspect of research; aims of research organization; research and technical schools; principles of general application in industrial-research laboratories.

Marine Engineering

Research in Marine Engineering. A. E. Seaton. Int. Mar. Eng., vol. 23, no. 7, July 1918, pp. 420-423. How lack of research has retarded progress in marine engineering; what it can accomplish. Paper read before the Inst. of Naval Architects, London, March 1918.

ROADS AND PAVEMENTS

Brick Pavements

The Bound Bases for Brick Pavements. John S. Crandell. Am. City, vol. 19, no. 2, August 1918, pp. 102-103. Suggested specifications for a tar-bound base for brick pavements. From an address before the Nat. Paving Brick Manufacturing Assn.

Concrete Pavements

Concrete Pavements. Murray A. Stewart. Can. Engr., vol. 35, no. 3, July 18, 1918, pp. 57-59. Recital of experimental work undertaken to ascertain the respective merits of different classes of concrete. Paper contributed to the 1917-1918 Trans. Am. Soc. of Mun. Improvements.

Construction of Concrete Pavements. J. L. Harrison. Eng. & Cement World, vol. 13, no. 13, August 1, 1918, pp. 27-29. Account of the behavior of a concrete road and general remarks regarding requirements of concrete for road use.

Costs

Ultimate Costs of Bituminous and Water-bound Macadams Nearly Equal in New York. Dudley P. Babcock. Eng. News-Rec., vol. 81, no. 2, July 11, 1918, pp. 87-90. Highway department investigation indicates that total tonnage affects cost but slightly; equation derived for the relation of ultimate cost to traffic tonnage.

Granite Paving Blocks

Granite Paving Block Industry. Stone, vol. 39, no. 7, July 1918, pp. 317-318. An account of the state of the industry throughout the country based on reports compiled under the direction of the U. S. Geological Survey.

Highways

Effect of Heavily Loaded Motor Trucks on Surfaced Highways. Western Eng., vol. 9, no. 8, August 1918, pp. 311-312. Discussion by several Eastern highway officials on the effect of motor-truck traffic on improved highways and of measures to be taken to protect such highways from deterioration. From the official magazine of the U. S. Office of Public Roads.

Problem of Highway Transportation. F. A. Seibarling. Eng. & Cement World, vol. 13, no. 2, July 15, 1918, pp. 23-26. Suggestions to adopt permanent construction on rural roads as a solution to the transportation problem.

Resurfacing

Who Pays for Resurfacing Pavements? Can. Engr., vol. 35, no. 4, July 25, 1918, pp. 83-86. Results of an investigation carried out by the Am. Soc. of Municipal Improvements regarding methods of securing and financing resurfacing of worn pavements followed by the principal cities of the United States and Canada.

Road Materials

Typical Specifications for Bituminous Road Materials. Bulletin No. 691 (60 pages), U. S. Department of Agriculture, July 10, 1918. Specifications offered by the Office of Public Roads and Rural Engineering and prepared partly from the results of its own experimental work.

Shrinkage of Road Materials

Determination of the Shrinkage of Gravel and Sand-Clay Mixtures Packed by Traffic. Roy M. Green. Good Roads, vol. 16, no. 5, August 3, 1918, pp. 39-40, 1 fig. Account of tests made and curve showing results obtained.

See also Engineering Materials (Road Materials).

SAFETY ENGINEERING

Electrical Accidents

Safeguarding the Home and Person from Electrical Accidents. Elec. Eng., vol. 52, no. 1, July 1918, pp. 25-36. Abstract from circular No. 75 of the U. S. Bureau of Standards setting forth the causes of electrical accidents.

Industrial-Plant Accidents

Reduction of Accident Hazard. R. L. Gould. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1057-1060, 1 fig. A discussion of the questions confronting the safety engineer in his endeavor to minimize the risk of accident in our industrial plants and suggestions for promoting the work.

Mine Accidents

Protective Devices of Electrical Equipments in Mine Against Gases and Moisture (in Japanese). M. Furuta. Denki Gakkwai Zasshi, no. 355, February 1918, pp. 191-215.

Quarry-Operation Accidents

Accident Prevention in Quarry Operation. William H. Baker. Eng. & Contracting, vol. 50, no. 3, July 17, 1918, pp. 59-61. Abstract from an address delivered before the Nat. Safety Council.

Smelteries and Refineries

Safety Appliances in Smelteries and Refineries. George M. Douglass. Eng. & Min. Jl., vol. 106, no. 3, July 20, 1918, pp. 105-108, 8 figs. Devices used in a modern plant. Causes of common accidents and their prevention.

See also Electrical Engineering (Lightning Arrester; Transmission Lines).

SANITARY ENGINEERING

Carbon Dioxide in Air

The Safe Limit of Carbon Dioxide in the Working Atmosphere. G. O. Higley. Am. Jl. of Public Health, vol. 8, no. 7, July 1918, pp. 477-481.

Disinfectants

Report of the Committee on Standard Methods of Examining Disinfectants. Am. Jl. of Public Health, vol. 8, no. 7, July 1918, pp. 506-521.

Sewerage

An Inventory and Prospectus for a Comprehensive Sewerage System. H. W. Taylor. Am. City, vol. 19, no. 2, August 1918, pp. 139-143. A recent development in the city of Glens Falls, N. Y.

Sewage Treatment in Sedalia. Mun. Jl., vol. 45, no. 2, July 13, 1918, pp. 23-25, 3 figs. Missouri city employing grit chamber, Imhoff tanks, sludge beds, dosing tank and sprinkling filters to avoid polluting a small stream.

Uses and Accomplishments of Chlorine Compounds in Sanitary Science. Charles H. Jennings. Fire and Water Eng., vol. 64, no. 3, July 17, 1918, p. 44. Extract from a paper read by Mr. Jennings before the Southwestern Water Works Assn. at its convention in Tulsa, Okla.

Soap Solutions

On the Bactericidal Efficiency of Soap Solutions in Power Laundry. H. G. Elledge and W. E. McBride. Am. Jl. of Public Health, vol. 8, no. 7, July 1918, pp. 494-498.

Water

Analysis and Quality of Water. Mun. Jl., vol. 45, no. 4, July 27, 1918, p. 71. Table showing the results of the analyses of water made by several hundred municipal plants. (Concluded.)

Chemical and Bacteriological Examination of the London Waters. A. C. Houston. Can. Engr., vol. 35, no. 5, August 1, 1918, pp. 98-100. Report of the Metropolitan Water Board of London.

Water Purification. R. A. Collect. Indian Industries & Power, vol. 15, no. 9, May 1918, pp. 389-393, 2 figs. Extensive description of a Paterson filter plant, with an explanation of purifying process. (Concluded.)

See also Marine Engineering (Fumigating Apparatus).

STEAM ENGINEERING

Boiler Construction

Engineering Specialties for Boiler Making. The Boiler Maker, vol. 18, no. 7, July 1918, pp. 202-204, 6 figs. Description of new tools, machinery, appliances and supplies for the boiler shop and of improved fittings for boilers.

Method of Determining Row of Least Efficiency in Boiler Seams. D. Shirrell. Loco., vol. 9, no. 2, August 1918, pp. 366-368, 1 fig. Offered proof that the least efficiency—i.e., whether this least efficiency is in the outer row of rivets through the single welt or in the outer row of the double welt, depends upon the ratio between the thickness of the boiler shell plate and the diameter of the rivet.

Condensers

Getting a High Vacuum at the Turbine Exhaust. Hartley LeH. Smith. Elec. Ry. Jl., vol. 52, no. 3, July 20, 1918, pp. 99-101. Shows how faults in condenser design are being overcome and emphasizes some fundamental considerations.

Recent Developments in Condensers. D. W. R. Morgan. Elec. World, vol. 72, no. 5, August 3, 1918, pp. 204-206, 4 figs. Necessity of efficient air removal in surface condensers; relative advantages of steam air ejectors and hydraulic and reciprocating air pumps; increasing use of jet condensers for large units.

Steam Condensers. J. H. Coates. Nat. Eng., vol. 22, no. 8, August 1918, pp. 358-361, 1 fig. Reasons for selecting one of the two general types of condensers for a given service. Abstract of a paper read before the Iowa State Convention, N. A. S. E.

The Problem of Condensing in Large Power Stations. J. H. Rider. Elecn., vol. 81, no. 9, June 28, 1918, pp. 172-174. Emphasis laid on large quantities of water necessary in a plant of 200,000 kw. Methods which may be used when the flow of water on a river site is insufficient, with figures showing reduction in vacuum which results. The limitations of cooling towers for large power stations.

High-Pressure Steam

Possible Economies by the Use of High-Pressure Steam. Frederick Samuelson. Elecn., vol. 81, no. 9, June 28, 1918, pp. 166-168, 4 figs. Considers improved efficiency obtainable by increasing both the temperature and pressure of the steam. Emphasizes economy obtainable by using steam from turbines for heating feedwater. Particulars of high-pressure steam plant at the Rugby works of the British Thomson-Houston Co., Ltd.

Steam Plant Design—Care for High Pressures and Temperatures. Times Eng. Supp., no. 525, July 1918, p. 147. Possibility of obtaining higher overall efficiencies in large power stations by the use of steam at higher pressures and temperatures than have hitherto been usual. Paper read by Mr. J. H. Shaw before the Inst. of Elec. Engrs.

Reciprocating Engines

A Uniflow Engine Installation. Iron & Coal Trades Rev., vol. 97, no. 2629, July 19, 1918, p. 53, 2 figs. Description of two 500 hp. Robey uniflow steam engines.

Steam Engine Economy. D. Arnot. Practical Engr., vol. 57, no. 1635, June 27, 1918, pp. 304-305, 3 figs. Exposition of methods used and summary of results obtained in tests on several types of engines. (Concluded.)

Steam Traps

Some Notes on Steam Traps. Machy. Market, no. 925, July 26, 1918, pp. 19-20, 4 figs. Expansive traps so constructed that the amount of expansion is magnified in such a way that the trap itself can be made considerably smaller. (Continuation of a serial.)

Turbines

Discussion on the Stal-Turbine (in Japanese). Denki Gakkwai Zasshi, no. 355, February 1918, pp. 161-167.

Small Steam Turbines. J. Humphrey. Iron & Coal Trades Rev., vol. 97, no. 2629, July 19, 1918, p. 53, 2 figs. Comments on their use in mines.

Turbines Furnish Additional Power. Coal Industry, vol. 2, no. 8, August 1918, pp. 304-306, 1 fig. How the exhaust steam from a reciprocating engine may be utilized to furnish additional power through a turbine-generator unit.

Value of Stal-Turbine as Land Electric Generator (in Japanese). K. Koyama. Denki Gakkwai Zasshi, no. 355, February 1918, pp. 215-231.

2500 Hp. Rateau Marine Geared Turbines. Engineer, vol. 126, no. 3263, July 12, 1918, pp. 36-38, 8 figs. Illustrated description of turbines and gears.

STEEL AND IRON

Briquetting Ores

Present Knowledge and Practice in Briquetting Iron Ores. Guy Barrett and T. B. Rogerson. Automotive Eng., vol. 3, no. 6, July 1918, pp. 261-263. Methods followed and machines used in briquetting iron ores and diagrammatic sketches of several presses. (To be continued.)

Electrical Resistance in Steel

On the Thermal and Electric Conductivities of Nickel Steels. Kôtarô Honda. Science Reports of the Tôhoku Imperial Univ., vol. 7, no. 1, July 1918, pp. 59-66, 2 figs. Investigation of Wiedmann-Franz' law establishing that the ratio of the conductivities

of two substances is independent of their nature.

The Effect of Annealing on the Electrical Resistance of Hardened Carbon Steels. I. P. Parkhurst. Jl. Indus. & Eng. Chem., vol. 10, no. 7, July 1918, pp. 515-518, 3 figs. Investigations showing that the total change in resistance increases with the carbon content and that the change is very rapid at the beginning of annealing but becomes slower as the resistance decreases.

Ferromanganese

Liquid Ferromanganese in Steel Making. Iron Age, vol. 102, no. 4, July 25, 1918, pp. 208-209. Advantages over using the solid alloy; type of melting furnace; cost and savings by one American steel maker.

Heat Treatment

Effect of Mass on Heat Treatment. E. F. Law. Mechanical World, vol. 63, no. 1637, May 17, 1918, p. 238. Abstract of a paper read before the Iron & Steel Inst.

Heat Treatment and the Hardening and Tempering of Steel. C. A. Edwards. Can. Machy., vol. 20, no. 4, July 25, 1918, pp. 82-86, 17 figs. Facts relative to heat treating in general of both carbon and alloy steels. From a paper read before the Manchester Assn. of Engrs.

Ingots

On the Distribution of Temperature in Steel Ingot During Cooling. Sêzô Saitô. Jl. of the Soc. M. E., Tokyo, vol. 21, no. 51, May 1918, pp. 15-30, 18 figs. Calculation of the distribution of temperature in cylindrical and rectangular ingots.

Macrostructure of Steel

Macrostructure of Steel (La macrostructure de l'acier). A. Portevin and V. Bernard. Revue de Métallurgie, year 15, no. 3, May-June 1918, pp. 273-280, 44 figs. Experimental determination of the structure of steel by means of the Stead-Le Chatelier reagent.

Nicu Steel

Nickel Copper—*Nicu* Steel. R. W. Leonard. Page's Eng. Weekly, vol. 33, no. 722, July 12, 1918, p. 19. Manufacture of nickel-copper steel. From a paper presented to the Can. Soc. of C. E.

Steel Ingots

Causes of Defects in Steel Ingots. J. N. Kilby. Iron Age, vol. 102, no. 5, August 1, 1918, pp. 266-269, 4 figs. Benefit of lime in acid open-hearth slags and the saving of manganese; temperature and speed of pouring. From a paper before the Iron & Steel Inst., London, May 1918.

Volume Changes of Steel

Expansion Changes in Nickel-Steels (Changements que provoquent dans la dilatabilité des aciers au nickel les actions thermiques ou mécaniques). Ch-Ed. Guillaume. Archives des Sciences Physiques et Naturelles, vol. 45, June 1918, pp. 407-417, 2 figs. Interpretation of experiments performed on different specimens of nickel-steel and determination of the change produced in the coefficient of expansion of these alloys by thermal or mechanical agents.

On the Slow Contraction of Hardened Carbon Steels. Tokujiro Matsushita. Science Reports of the Tôhoku Imperial Univ., vol. 7, no. 1, July 1918, pp. 43-52, 4 figs. Investigation of the gradual evolution of heat accompanying the contraction of hard carbon steel.

TESTING AND MEASUREMENTS

Electrical Measuring Apparatus

The Temperature Coefficient in Electrical Measuring Apparatus (El coeficiente de temperatura en los medidores eléctricos). Boletin de la Asociacion Argentina de Electro-Técnicos, vol. 4, no. 1, January 1918, pp. 615-617. Beginning of an article proposing the adoption of several tests to be performed on electrical measuring apparatus in order to rate their accuracy.

Hardness

Notes on Testing Hardness of Metals. J. W. Craggs. Scientific Am. Supp., vol. 86, no. 2223, August 10, 1918, pp. 94-95. Discussion of the use and application of the methods for testing hardness.

Resistance of Materials (Résistance des Matériaux). H. Le Chatelier and A. Bogitch. Académie de Sciences, vol. 166, no. 21, May 27, 1918, pp. 840-843. Comparison of the results on the hardness of materials of construction obtained by the use of Brinell's ball with the data derived by other methods.

Heat-Measuring Instruments

Requirements in Treating Materials. J. F. Beall. Am. Drop Forger, vol. 4, no. 7, July 1918, p. 283. Development of heat-measuring instruments.

Impact Tests of Steel

The Tension, Impact and Repeated Impact Tests of Mild and Hard Steels. Tsuruzo Matsumura. Jl. of the Soc. M. E., Tokyo, vol. 21, no. 52, June 1918, pp. 1-11, 16 figs. Result of comparative tests on steel bars of various grades of hardness.

Refractometer

A Differential Refractometer. G. A. Shook. Louisiana Planter & Sugar Manufacturer, vol. 61, no. 4, July 27, 1918, p. 58, 2 figs. Attempt to develop an instrument for measuring the difference in refractive index between two liquids.

Sand

Testing Sand for Concrete. Eng. & Cement World, vol. 13, no. 2, July 15, 1918, p. 70. Color test for detecting the presence in sand of organic impurities of a humus nature which would render concrete unfit for use in high-grade work such as is required in roads, pavements or in building construction.

Viscosity Measurement

Measurement of the Viscosity of a Fluid with a Galvanometer (Application du galvanomètre à cadre mobile à la mesure de la viscosité des fluides). Revue Générale de l'Electricité, vol. 3, no. 26, June 29, 1918, p. 938. Additional notes on the method of measuring the viscosity of a liquid by comparison to the viscosity manifested in induction phenomena submitted to the French Soc. of Physics by M. A. Guillet and published in the issue of May 1918.

THERMODYNAMICS

Heat Transmission

Heat and Heat Transmission. John R. Allen. Eng. & Contracting, vol. 50, no. 4, July 24, 1918, pp. 79-80. Constants for heat transmission, heat losses from infiltration, radiation and radiators, determining pipe sizes. From a paper before the Am. Soc. of Heat. & Vent. Engrs.

Latent Heat of Steam

Regnault's Latent Heat of Steam Investigations. Frank B. Aspinall. Engineer, vol. 125, no. 3260, June 21, 1918, pp. 525-527, 1 fig. A careful review of Regnault's apparatus, his fallacious assumptions and his erroneous conclusions.

See also Power Plants (Piping).

TIMBER AND WOOD

Fireproofing Wood

Fireproofing Mine Shaft of the Anaconda Copper Mining Co. E. M. Norris. Eng. & Min. Jl., vol. 105, no. 25, June 22, 1918, pp. 1126-1127, 1 fig. Fireproofing mine timbers by a cement coating on the timbers, which had been covered with metal lath. Cement applied with cement gun.

Relative Resistance of Various Hard Wood to Injection with Creosote. C. H. Teesdale. Railroad Herald, vol. 22, no. 8, July 1918, pp. 167-170, 1 fig. Results of experiments made at the Forest Products Laboratory, maintained by the Forest Service, U. S. Department of Agriculture, in coöperation with the University of Wisconsin.

Lumber Industry

The Uses of Wood. Hu Maxwell. Am. Forestry, vol. 24, no. 295, July 1918, pp. 419-427. Third of a series of articles covering the processes of logging, lumbering, transportation, milling, utilization and manufacture of wood.

Timber Industry. Percy Groom. Jl. of the Royal Soc. of Arts, vol. 66, no. 3424, July 5, 1918, pp. 515-524. Extent to which technical science can aid in promoting the timber industry and the utilization of the timber resources of the British Empire.

Valuation of Public Service Property. A. S. B. Little. Gas Age, vol. 42, no. 2, July 15, 1918, pp. 57-59. A technical discussion of theories and practices employed in fixing values, from the viewpoint of a State Commission engineer.

Volume of Gas in High-Pressure Tanks. J. M. Spitzglass. Gas Jl., vol. 143, no. 2878, July 9, 1918, p. 69. Determination of a rule to find the volume of a gas at high pressure from the characteristic gas equation.

Would Rate State Highway Contractors on Past Performance. S. E. Fitch. Eng. News-Rec., vol. 81, no. 3, July 18, 1918, pp. 125-127. Proposes giving contractor part of saving under estimated cost and advantage in bidding proportionate to speed and efficiency shown.

WOOD

(See Timber and Wood.)

THE NATIONAL ENGINEERING SOCIETIES AND THE NATIONAL RESEARCH COUNCIL

By DR. GEORGE ELLERY HALE,[1] PASADENA, CAL.

DR. GEORGE E. HALE

IN an address delivered in the Engineering Societies Building on May 28, at the kind invitation of the Engineering Foundation, I briefly sketched "The War Activities of the National Research Council." The wide scope of my subject, calling for some reference to the work of the Council in the various branches of the physical and biological sciences, as well as in agriculture, medicine, and other arts, forced me to touch very lightly upon engineering. I therefore beg permission to return to this phase of the subject in the present paper.

As shown in the address just cited, the charter membership of the National Academy of Sciences, constituted in the midst of the Civil War, comprised a notable group of engineers. Indeed, engineering was the only one of the arts represented in the Academy, which based its elections, then as now, upon creative work and original contributions to knowledge. The war was the immediate stimulus that led to the establishment of the Academy, but the published opinions of well-known visitors from abroad indicate that there was urgent need for such a body in this country.

De Tocqueville, in a chapter entitled "How the example of the Americans fails to prove that a democratic people cannot possess aptitude and taste for science, literature and art," wrote in 1840 as follows: "It must be admitted that among the civilized peoples of our time there are few in which the higher sciences have made less progress than in the United States."[2] This he attributed to our Puritan origin, our pursuit of the wealth which is so easily acquired in a new country, and our dependence upon England for intellectual things. "I consider the people of the United States as that portion of the English people which is charged with the exploitation of the forests of the new world, while the rest of the nation, enjoying more leisure and less preoccupied with the material needs of life, may devote itself to thought and to the development of the human mind in every field."[3]

But although he regarded the United States as exceptional, he fancied that he recognized in all democracies conditions of disturbance and unrest which leave little opportunity for the quiet and repose essential to the cultivation of science. These he carefully distinguished, however, from great upheavals of the body politic. "When a violent revolution occurs among a highly civilized people, it cannot fail to give a sudden impulse to feeling and imagination."[4] Thus the French achieved their highest development in science soon after the revolution of 1789.

In 1863, when the National Academy was incorporated, De Tocqueville would probably have considered our intellectual dependence upon England to be materially less than at the time of his visit to the United States, thirty years earlier. Doubtless he would have attributed the improved condition of American science to the effect of the Civil War, and the considerable increase in wealth and leisure. In 1873, if we may judge from Tyndall's remarks in the concluding lecture of his American series, European opinion saw hope for the future of science in the United States, but recognized few important accomplishments. "If great scientific results are not achieved in America, it is not to the small agitations of society that I should be disposed to ascribe the defect, but to the fact that the men among you who possess the endowments necessary for profound scientific inquiry are laden with duties of administration, so heavy as to be utterly incompatible with the continuous and tranquil meditation which original investigation demands."[5] At this time Henry was secretary of the Smithsonian Institution, Barnard was president of Columbia College, and Rogers was president of the Massachusetts Institute of Technology. There was thus some justification for Tyndall's remark, though the amount of scientific research in progress was much larger than one would infer from his statement of the case. Moreover, though deprived by other duties of the privilege of personal work in the laboratory, these very men, charter members of the National Academy, were, nevertheless, laying the foundations of science in America. By uniting in one national body the representatives of research in both science and engineering they set an example which their successors should keep steadily in view.

The half century which elapsed before the United States was again stirred to its depths by another great war was a time of specialization, both at home and abroad. Once fairly launched, both science and the arts made rapid progress, but they inevitably grew apart. Indeed, the tendency toward specialization which divided the arts from the sciences also separated the sciences into many distinct groups and split the arts widely asunder. Thus in engineering many societies were organized, first those comprising the major fields of civil, mechanical, mining and electrical engineering, subsequently those dealing with the special problems of naval architecture, illumination, refrigeration, and still more narrowly limited branches. At the same time numerous major and minor societies were formed in the general field of medicine; others marked out special territories in the name of agriculture, forestry and fisheries; and the process of subdivision and separation still goes on.

It is plain that these effects of specialization, while natural and essential elements in the development of science and the arts, involve certain consequences which are far from advantageous. The underlying motive of the investigator, to advance knowledge and to improve practice through the utilization of new ideas, is common to all fields of action. His point of view is much the same, whether his problems be those of the biologist or the engineer. Moreover—and this is a matter of prime importance—the principles and methods of research developed in one field may be equally applicable in another.

[4] Op. cit. p. 70.

[5] Six Lectures on Light, 2nd ed., p. 226.

Thus there is an essential solidarity of research which should bring into active cooperation the men engaged in all of its various branches. Recent experience, both in peace and war, has shown how effectively the physicist and chemist can join forces with the engineer: in fact, how men drawn from the most diverse fields can utilize their varied experience to common advantage.

The remarkable development of engineering in the United States is indicated by the success of the four great national societies, which aggregate more than 30,000 members. Nine-tenths of the work of the engineer is organization and construction rather than research. While the chief interests of the national societies thus lie in other fields, the importance of research is such as to demand a large measure of support from each of them. Moreover, great benefit will result from a joint effort, involving the coöperation of the national engineering societies with the National Academy of Sciences in a new and powerful movement to promote research in every branch of science and the arts. The establishment of the National Research Council, and the duties laid upon it by the President in his recent Executive Order, plainly indicate the steps to be taken.

It is natural that the first effective contact between the National Academy of Sciences and the national engineering societies should have been established through the Engineering Foundation, endowed by Mr. Ambrose Swasey, Past-President Am.Soc.M.E., a mechanical engineer who has contributed greatly to the progress of astronomy through the perfection of the powerful telescopes built by the firm of Warner and Swasey. It is equally natural that the engineers who, with Mr. Swasey, took leading parts in the movement toward a consolidation of interests were also men fitted by experience to appreciate both sides of the question. The National Academy owes a special debt of gratitude to Mr. Gano Dunn, Mem.Am.Soc.M.E., who immediately grasped the purpose in view and has worked unceasingly toward its accomplishment. Though prevented by his heavy responsibilities as a construction engineer from conducting research in a professional way, Mr. Dunn's private activities as an investigator are well known to his friends, who therefore understand how wholeheartedly he has devoted himself to the task of breaking down the artificial barriers between the engineer and the man of science. Others who were most active in the initiation of the movement, including particularly Colonel Carty and Dr. Pupin, also combine experience in research with exceptional capacity as engineers. With their effective aid, and with the active support of the officers of the Engineering Foundation and those of the national societies, the difficulties of the initial steps were soon removed and the way was prepared for the intimate coöperation subsequently realized.

The National Academy, probably because of the general tendency toward separate development of the arts and sciences already mentioned, failed to maintain on its rolls the same percentage of engineers with which it originally set out. At the annual meeting in April 1916, however, the following resolution, presented by the Council, was adopted by the Academy:

> That the Council express to the Academy the opinion that it is desirable that a section of engineering be developed which shall include men who have made original contributions to the science or art of engineering; that to this end the Council suggests to the Academy that the present section of physics and engineering be designated the section of physics, and that the Council, under the authority granted by section 4, article 4, of the constitution, nominate to the Academy, after inviting suggestions from the members of the Academy, two or three engineers each year until such time as it shall seem advisable to establish a separate section of engineering, any engineers elected as the result of such nominations being in the meantime assigned to that one of the existing sections to which their work is most closely related.

Since that time six eminent engineers have been elected to membership in the Academy, and the Section of Engineering will soon be established.

Another means of connection between the Academy and the engineering profession was initiated at the same meeting. Our relations with Germany, after repeated submarine attacks on merchant ships, were in a state of high tension, and the need of some preparation for coming war was plainly evident. The Academy's offer of service to the President was at once accepted, and the National Research Council was formed, at the President's request, for the purpose of federating the research activities of the country.[1]

The first duty laid upon the National Research Council by President Wilson in his Executive Order of May 11, 1918, reads as follows:

> 1 In general, to stimulate research in the mathematical, physical and biological sciences, and in the application of these sciences to engineering, agriculture, medicine and other useful arts, with the object of increasing knowledge, of strengthening the national defense, and of contributing in other ways to the public welfare.

This definition of the scope of the Council indicates its purpose to give equal attention to research in all branches of science and the arts. The Council fully recognizes the solidarity of research to which reference has already been made, and its efforts will be directed to promoting the closest coöperation between investigators in every field. It should be clearly understood that the National Research Council was not organized as an independent body, but as a means of federating existing research agencies.

War Duties

It is a matter of prime importance that in all researches bearing on the war the scientific and technical societies of the entire country should work in close coöperation, both to avoid unnecessary duplication and to insure the utilization of all ideas and facilities available for the solution of the most difficult problems. The National Research Council affords the necessary means of bringing representatives of these bodies together and into contact with the various technical bureaus of the Army and Navy and other departments of the Government. The advantages afforded by the Research Information Service, and the other facilities for international coöperation provided by the Council, are described below. Here we may observe how some of the work in engineering is conducted.

The appointment of Mr. Gano Dunn as chairman and Dr. W. F. Durand as vice-chairman of the Council's first Engineering Committee insured that its work would be ably directed. Mr. Dunn's engineering duties made it necessary for him to retain his headquarters in New York, but his close contact with the Engineering Foundation and the national societies proved very advantageous. His activities, in fact, led directly to the Council's first step in securing general coöperation in the organization of researches bearing on the submarine problem. In the initiation and development of many other undertakings he played an equally important part. Dr. Durand's joint duties in Washington, as vice-chairman of the Engineering Committee and as chairman of the National Advisory Committee for Aeronautics, gave him opportunity for valuable work in the organization and conduct of many in-

[1] See War Activities of the National Research Council.

vestigations of an engineering nature. When the Research Information Committee was established, Dr. Durand's qualifications for the position of scientific attaché and representative of the Research Council in Paris were so exceptional that he was transferred to this important post.

As a typical illustration of the work of the Engineering Committee, we may mention the organization and activities of the special Sub-Committee on Protective Body Armor, which includes in its membership the curator of arms and armor of the Metropolitan Museum of Art, representatives of the Ordnance Department of the Army, well-known metallurgists, and several able engineers experienced in different fields. The close coöperation of this sub-committee with the Ordnance Department enabled it to carry on its work very effectively, and to make all necessary tests of the special types of helmets and body armor that were devised. The form of the helmet was materially influenced by the extensive knowledge of ancient armor possessed by Dr. (now Major) Bashford Dean, who also went to France to familiarize himself with conditions of trench warfare. The value of this experience has been abundantly proven by the tests to which the helmets have recently been subjected. The metallurgical experiments were carried out in Dr. Howe's own laboratory. The results of the sub-committee's work promise to be of great practical importance in the protection of our troops.

Another illustration of the work of the Engineering Committee, which unfortunately cannot be given in detail because of the confidential nature of the problem, is the development of a special form of gun for the Ordnance Department of the Army. This involved the coöperation of several engineers, machine designers drawn from universities and other organizations, ordnance experts, and manufacturing establishments.

Without going into further details of many other research problems studied by the Engineering Committee, we may now turn to the work of the recently organized Engineering Division, which the natural development of the work of the Research Council has brought into existence. The constantly increasing demands upon Mr. Gano Dunn's time resulting from the large war contracts upon which his firm is engaged, and the departure of Dr. Durand for France, made it necessary to select new officers to carry on the engineering work in Washington. Dr. Henry M. Howe was accordingly made chairman, and Mr. W. J. Lester vice-chairman of the Engineering Division, the purpose of which is described in the following excerpt from the remarks of Dr. Howe at the first meeting of the Advisory Committee of the Division.

After referring to the establishment of the National Research Council, and speaking of its general purposes, Dr. Howe went on to describe the object of the meeting:

It is to consider how we may best carry out this general purpose of "coördinating the scientific resources of the entire country," as regards engineering and how we may best "secure the coöperation of all engineering agencies in which research facilities are available" that you have been called together. We are asked to do something wholly new, and, by the intentional breadth of our charter, we are in effect told to devise ways of doing it. We have a free hand.

Let me tell you what plans we have already made in this early and formative stage of our growth: Our most pressing duty is to help the existing governmental agencies in every possible way to win the war, taking the attitude that, however perfect their several organizations, after all they are finite, that is, limited, whereas the demands which the most rapid possible development of our military strength makes on them are unlimited. We therefore seek and welcome ways of helping them. In general our natural function here has been to develop ideas, often initially nebulous, far enough to make their usefulness clear to the military authorities, using this term broadly to include the land, sea, and air forces, and then to leave the active production to them. In many cases our work is confined strictly to perfecting the design, in other cases models have to be made. In this way the Division of Physics has developed a great number of very important instruments and devices relating to submarine, subterranean, aircraft, and other matters, and the Division of Medicine and Related Sciences, besides organizing many researches in medicine, has developed a system of psychological tests which have been adopted in the Army for both officers and privates.

Our own division has already formed five sections,—on mechanical engineering under Mr. W. J. Lester, prime movers under Prof. Lionel S. Marks, Mem.Am.Soc.M.E., metallurgy under Dr. Bradley Stoughton, Mem.Am.Soc.M.E., electrical engineering under Dr. Stoughton and Prof. C. A. Adams, Mem.Am.Soc.M.E., and military "tanks," and we ask your advice today about forming others on ordnance, clearing house, and the fatigue of metals. The National Advisory Committee for Aeronautics acts as our section on aircraft. Our section on metallurgy has two important committees, on helmets and on body armor under Major Bashford Dean, and on smelting ores of manganese under Mr. J. E. Johnson, Jr., Mem.Am.Soc.M.E.

How we may "secure the coöperation of engineering agencies," as President Wilson wishes, is illustrated first by our working in close coöperation with the Bureaus of Mines and Standards, the latter of which has placed a laboratory at my disposal, and second by our research on the saving of manganese in steel making by replacing it in part with deoxidizing agents.

Here the deoxidizing agents used must bear such a ratio to each other that the sum of the resultant oxides will be fusible at the steel-making temperature, and hence will coalesce and rise to the surface by gravity instead of remaining entangled in the steel to its great harm. But before we can do this we must learn what the fusible combinations of the oxides of available deoxidizing agents are. To this end we have secured the coöperation of the Geophysical Laboratory, whose Dr. R. B. Sosman is one of the first, if not the first, authority on this subject, to select the most promising field, and we are now seeking the coöperation of a large number of laboratories, industrial, educational, and governmental, in determining the actual melting points of large numbers of these combinations of oxides. We thus seek a truly scientific solution of the problem instead of one by trial and error. Here we may have as many as twenty separate institutions collaborating on this one problem, with corresponding saving of time.

It is to be hoped that our present coöperation with the Bureaus of Standards and Mines may be matched by like coöperation with the Naval Consulting Board, whose important work of sifting out the promising inventions from the great mass submitted to it seems to be well complemented by our natural work of developing promising ideas.

Dr. Howe then discussed the question of the men needed and the expenses involved in the proposed work. The Engineering Division of the Research Council already has $30,000 available for its office and organization expenses during the current year, and additional funds will probably become available in the near future.

Since that meeting the work of the Sections on Mechanical Engineering and on Metallurgy has developed rapidly. The former has taken over the laboratories and machine shop of the Carnegie Institution at Pittsburgh so as to control the construction of the devices which it is perfecting. Through its Committee on Fatigue, under the chairmanship of Prof. H. E. Moore of the University of Illinois, it has begun the systematic study of fatigue phenomena, having especially in view the requirements of aircraft crankshafts and welded ship plates. It has brought the development of two special types of guns so far that one is now ready for firing, while the other will probably be fired before this paper is in print. Beyond this it is actively developing ten devices, a special gun for use in aircraft, a special mechanism for controlling it, a new control for aircraft, aircraft fuel, tanks of various types, mechanism for controlling trucks, a new type of tractor, special telescopes, special balloons, parachutes, and a new type of aircraft engine.

The work of the Section on Metallurgy promises to develop chiefly through the creation and direction of committees which shall mobilize the latent skill and patriotism in the metallurgical works themselves and in their laboratories, metallurgical, chemical and mechanical, and in the laboratories of our institutions of learning. Thus in addition to the committees mentioned by Dr. Howe, this Section has organized, under the chairmanship of Col. W. P. Barba of the Ordnance Department, a committee containing the metallurgists of the great ordnance works, Bethlehem, Midvale, Standard and the United States Steel Corporation, to formulate detailed directions for the procedure in making and treating steel ingots for objects needing the very best quality, such as cannon, shells, armor and crankshafts. Under the chairmanship of Dr. George K. Burgess, of the Bureau of Standards, it is now organizing a committee to develop a pyrometer for determining the temperature of the molten steel in the open-hearth and electric steel processes. Other committees with aims of this general class are projected.

RESEARCH INFORMATION SERVICE

The organization and work of the Research Information Committee, which now has offices in Washington, London, Paris, and Rome, were described in the address previously cited. The subsequent action of the Secretary of War in issuing the following general order to all scientific and technical bureaus of the War Department has led to an important expansion of the work of the Committee.

1 The Secretary of War directs that you be informed as follows:

2 The Research Information Committee was formed to establish machinery by means of which the general staff of the Army, the various bureaus of the Army and Navy, the Scientific Organizations in the United States, who are working on problems connected with war production and invention, and the various committees of the Council of National Defense charged with work of this nature, may be put in touch with the developments and experimental work being carried on, not only in this country, but in Europe, and kept mutually informed of the state of development of work of this nature.

3 In pursuance of the order of the Secretary of War establishing this Committee and in order effectively to do this work, it is vitally necessary that the utmost of cordial coöperation be shown by each of the bureaus and committees in question with the Research Information Committee. To secure this the following is directed:

a All Military Bureaus requiring scientific and technical information are given official status on the Research Information Committee in Washington, D. C.

b Representatives of Military Bureaus or of research committees collecting information abroad will be instructed, by their chiefs, to put themselves into direct relationship with the joint committees of the Research Information Committee sitting in Paris or London, or later in Rome, in order that information be at once dispatched to the Research Information Committee at Washington, D. C. All communications of scientific investigations or research shall be routed through these channels, even though other channels are employed at the same time.

c Official means of intercommunication, such as memoranda, bulletins and the like, between Bureaus of the Army and Committees for research shall be developed to such a degree of efficiency by the Research Information Committee that the distribution of information shall be practically automatic.

d Before sending officers or civilians abroad for investigation work, all Army Bureaus or civilian research committees shall get in touch with the Research Information Committee at Washington, D. C., for information and guidance.

e The present method of routing information memoranda for file and distribution through the Military Intelligence Branch will not be discontinued.

f You will immediately notify this office and the Research Information Committee of the name of the officer who shall represent your Bureau before the Research Information Committee.

By order of the Secretary of War:
(Signed) PAUL GIDDINGS, *Adjutant General.*

In accordance with the principles embodied in this order of the Secretary of War, the organization of the Research Information Service has been expanded to include official representatives of all the military and naval bureaus, together with the more important Government civilian bureaus and committees. The present organization of the Washington and foreign offices is given below. A meeting of the Washington representatives was held on August 29, when plans for perfecting the operation of the service were developed.

PRESENT ORGANIZATION OF RESEARCH INFORMATION SERVICE

COMMITTEE IN CHARGE:

The Chief of the Military Intelligence Branch, Brig.-Gen. Marlborough Churchill.

The Director of Naval Intelligence, Rear-Admiral Roger Welles.

The Chairman of the National Research Council, who acts as general executive officer of the Information Service.

WASHINGTON BRANCH:

Officers:

Executive Secretary, Dr. Graham Edgar.

Representative of Physics and Engineering.

Representative of Chemistry and Chemical Technology, Dr Graham Edgar.

Representative of Medicine and Related Sciences, Dr. R. M. Pearce.

Representatives of Military Bureaus:

Division of Military Aeronautics, Capt. A. Ames.

Military Intelligence, Capt. P. M. Buck.

Bureau of Ordnance, Major C. J. Brown.

Quartermaster General, Major W. F. Dodd.

Office of the Signal Corps, Capt. G. F. Gray.

Chemical Warfare Service, Major S. P. Mulliken.

Tank Corps, Capt. Phil D. Poston.

Engineer Corps, Capt. L. D. Rowell.

Office of Surgeon-General, Col. F. F. Russell.

Bureau of Aircraft Production.

Representatives of Naval Bureaus:

Office of Naval Intelligence, Lieut.-Com. H. H. Whittlesey.

Bureau of Steam Engineering, Lieut. M. Pendleton.

Bureau of Construction and Repair, Capt. W. G. Du Bose.

Operations—Aviation, Ensign A. F. Lippmann.

Bureau of Ordnance, Ensign C. L. McCrea.

Representatives of Civilian Bureaus:

War Industries Board.

Bureau of Standards, F. J. Schlink.

Bureau of Mines, Dr. F. G. Cottrell.

Bureau of Chemistry, Dr. H. D. Gibbs.

Explosives Investigations Committee, Dr. C. E. Munroe.

Nitrate Investigations Committee, Dr. John Johnston.

National Advisory Committee for Aeronautics, Dr. W. G. Sabine.

Representatives of Foreign Missions

British Embassy and War Missions.

French Embassy and War Missions.

Italian Embassy and War Missions.

Japanese Embassy and War Missions.

Canadian War Mission.

LONDON BRANCH:

The Military Attaché.

The Naval Attaché.

Scientific Attaché, Dr. H. A. Bumstead.

Engineering Associate, Dr. S. J. Farnsworth.

Chemical Associate.

PARIS BRANCH:

The Military Attaché.

The Naval Attaché.

Scientific Attaché, Dr. W. F. Durand.
Physics Associate, Dr. K. T. Compton.
Chemical Associate.
Medical Associate, Dr. R. G. Perkins.

Rome Branch:
The Military Attaché.
The Naval Attaché.
Scientific Attaché, Mr. S. L. G. Knox.
Physics Associate, Dr. Edgar Buckingham.
Chemical Associate, Dr. H. S. Washington.

In this field there will necessarily be close coöperation between the National Research Council and the National Engineering Societies, already well begun through the acceptance of the offer of the American Society of Mechanical Engineers referred to in the address so frequently cited. The policy of the Information Service will be to render available to accredited persons all sources of information relating to research, both at home and abroad. Its chief function at present will relate to the war; but this naturally includes extensive duties of an industrial nature, in addition to more strictly military and naval work. Through the scientific attachés at the various embassies, the Army and Navy Intelligence Services, and the officers of the scientific and technical bureaus of the Government, and through various other agencies with which the National Research Council is in touch, a large collection of valuable information is being brought together and collated for easy reference.

International Coöperation in Research

The work of the Research Information Service, which has already led to the establishment of the position of Scientific Attaché by the State Department, is part of an extensive plan for international coöperation in research which is being developed by the National Academy of Sciences and the National Research Council. A detailed plan for coöperation among the Allies in all researches bearing on the war has been prepared by the Council of the National Academy, for submission at a meeting soon to be held in London, at which the United States will be represented by a delegation appointed by the National Academy.

It is evident that each of the national engineering societies, in addition to its special reasons for securing effective international coöperation in its particular field, has broader interests that necessarily involve joint action with the representatives of other branches of science and the arts. The plan prepared by the National Academy provides a means, through the Section of Foreign Relations of the National Research Council, by which such joint action can be arranged for. While the time is not yet ripe to enter into the details of the scheme, it is worthy of mention here because of its bearing upon the subject of this paper.

Industrial Research

I may conclude this paper with a brief reference to the common interests of the national engineering societies and the National Research Council in the promotion and organization of industrial research, already mentioned in my New York address. The members of the Advisory and Active Committees of the Industrial Relations Section of the National Research Council dined together in New York on May 29. Among the speakers who strongly emphasized the importance of promoting industrial research were Hon. Elihu Root, Mr. Theodore N. Vail, Col. J. J. Carty, Mr. Ambrose Swasey, Dr. Henry S. Pritchett, Mr. Pierre S. duPont, Mr. George Eastman, Mr. Arthur H. Fleming, Dr. L. H. Baekeland, President Richard C. Maclaurin, Dr. M. I. Pupin, and Dr. Willis R. Whitney. Mr. Theodore N. Vail was elected chairman of the Advisory Committee, and it was decided to organize the work of the Section and to begin the publication of a series of bulletins on the value of research and the advantages resulting from the establishment of research laboratories. The Active Committee, of which Dr. John Johnston is chairman, has stimulated the organization of several successful conferences on research in the industries, and the outcome of its work is very promising.

Here is a field where the engineering societies and the Research Council can coöperate to special advantage through the Engineering Foundation, which is already taking an active part. The possibilities of developing this work, through the establishment of special laboratories and by other means, are obvious, and advantage will be taken of the present exceptional opportunity to influence favorably the industries which have hitherto failed to appreciate the value of research.

THE RELATIVE CORROSION OF ALLOYS

By R. B. FEHR,[1] DAYTON, OHIO

In order that the results obtained by different experimenters may be comparable and lead to definite conclusions regarding laws of corrosion, standards should be adopted in regard to such matters as dimensions of specimens, preparation of surfaces, amount of corroding medium, method of suspension in medium, temperature, access of light, duration of test, diffusion, cleaning and weighing of specimen, method of expressing relative corrosion, and, perhaps most important of all, the nature of the corroding medium.

The ultimate aim should be to devise a comprehensive series of tests to which standard specimens of materials may be subjected, and by which the relative corrodibilities of these different materials may be predicted for certain service conditions. A great amount of systematic research work would have to be done before a satisfactory set of standards could be devised, but the problem is somewhat simplified by the fact that relative values of corrosion are desired rather than absolute values. Consequently, it will probably be found that a few tests will cover in a qualitative way the most usual conditions that are met with in practice.

One of the most important factors that would be involved in any proposed standard method is the time element. Al-

[1] Assistant Physicist, Recording and Computing Machine Company. Jun.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 3 to 6, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. The paper will also appear later as Bulletin No. 27 of the Engineering Experiment Station of Pennsylvania. All papers are subject to revision.

though the best test of the usefulness of a material is, of course, the actual service test during a long period of time, no engineer would think of building a machine or structure without first making strength tests of samples of the materials used; and in like manner he would prefer to have some comparatively simple means for determining the relative corrosion of materials before deciding upon the best one to use under the particular conditions involved, without having to wait for the test of time on his completed structure.

To meet this short-time requirement, various so called "accelerated" corrosion tests have been devised, the principal corroding media being sulphuric acid and sea water or other salt solutions. These methods have met with much opposition for the reason that they do not imitate and therefore cannot intensify natural corrosion influences, as they were intended to do. The results thus obtained are not in agreement with those obtained under practical service conditions. This is not surprising, for it is now becoming generally recognized that the relative corrodibilities of different materials vary with the nature of the corroding media. What may be highly resistant under one set of conditions may be highly corrodible under a different set of conditions.

Since accelerated tests are not regarded as trustworthy, and also since long-time tests are not feasible, it becomes necessary to adopt some compromise between the one- or two-hour period of accelerated tests and the many years of the actual service tests. Some preliminary tests conducted by the writer led to the conclusion that trustworthy results could be obtained within a period of a few weeks, provided analytical balances were employed and the same care exercised as in quantitative chemical analysis. Of course, small test specimens would have to be employed. The objection might be urged that small specimens would not be representative of the material, but duplicate or triplicate samples, combined with greater uniformity of preparation and accuracy in weighing would more than offset this nominal disadvantage.

Methods Previously Employed for Corrosion Tests

Not only is it necessary to adopt standard methods of testing, but it is equally important to agree upon some uniform method of expressing the results. The following methods have been employed:

a Loss of weight (specimens of practically the same original weight)

b Per cent loss of weight

c Loss of weight per unit area of exposed surface

d Appearance as judged by the naked eye or lens.

Methods *a*, *b* and *c* are satisfactory if the conditions of testing are exactly the same within experimental limits of accuracy. Methods *a* and *c* do not give correct relative values of the corrodibilities of materials that differ appreciably in density. Method *b* does not have this objection, but like *a* it does not take into account important differences in the ratios of exposed surface to volume. Method *d* is merely qualitative and depends upon personal judgment, but is useful for cases of unequal corrosion, or pitting, as will be noted later.

Proposed Method for Indicating Relative Corrodibility

Although experiments run under different conditions with respect to weight, density and exposed surface of the specimens can never be considered strictly comparable, a much better measure of the relative corrodibilities of materials can be gained by applying the following method of reasoning:

Suppose, by way of example, that a certain corroding medium gave the results on specimens of different materials having dimensions as noted in Table 1. This example is a somewhat extreme case, but it sometimes requires an extreme case to emphasize a point. A study of the results obtained by the three methods *a*, *b* and *c* is interesting in that they appear to indicate four, three, and two different values, respectively, for the relative corrodibilities, whereas in reality the four materials have the same corrodibility, as further consideration will easily show.

TABLE 1 ILLUSTRATIVE CORROSIVE RESULTS ON DIFFERENT MATERIALS

Specimen	Weight, grams	Volume, c.c.	Surface, sq. cm.	Sq. cm. c.c.	(*a*) Loss, gr.	(*b*) Loss, %	(*c*) Loss, gr./sq cm.
1	15	3	75	25	1.5	10.0	0.020
2	15	3	150	50	3.0	20.0	0.020
3	30	3	150	50	6.0	20.0	0.040
4	30	3	300	100	12.0	40.0	0.040

What really counts in corrosion is the volume of material removed in a given period of time on each unit of surface, and not the loss in volume per unit of volume, nor the loss in weight per unit of surface, etc., for these latter methods do not take into account the differences in density and exposed surface of the specimens, which differences are certainly no fault of the materials. For instance, specimen No. 2 has the same density, but twice the exposed surface of No. 1. If it were of the same material as No. 1 it would be expected to lose twice the weight, and yet it would be manifestly unfair to say that the relative corrodibilities are different, as indicated by methods *a* and *b*.

Again, No. 3 has twice the density of No. 2, and if it had the same corrodibility it should lose twice the actual weight, as well as twice the weight per unit of surface. Therefore, provided all other conditions were the same in these cases, the only method that would indicate equal corrodibility would be method *b*, on account of the cancelling out of the density factors.

Obviously, then, none of the methods employed thus far indicates the true relative corrosion values for specimens of different sizes from different materials. However, if the results obtained by method *b* in Table 1 are divided by the respective values for the ratio of surface to volume, the results will be 0.40 in each case, and thus a true measure of the relative corrodibility is obtained.

The algebraic derivation of this method is as follows:

Let a = area of *exposed* surface of test specimen, sq. cm.
v = volume of specimen, cu. cm.
d = density of material, grams per cu. cm.
w = original weight of specimen, grams
s = loss in weight in grams by method (a)
p = per cent loss in weight by method (b)
K = relative corrosion by proposed method, per cent of cu. cm. per sq. cm. of surface.

$$p = \frac{s}{w} \times 100$$

$$= 100\,\frac{\frac{s}{d}}{\frac{w}{d}} = 100\,\frac{\frac{s}{d}}{v} = \text{per cent loss of volume,}$$

since the volume equals weight divided by density.

$\frac{a}{v}$ = ratio of surface to volume,

and

$$\frac{p}{\frac{a}{v}} = 100\,\frac{\frac{s}{d}}{v} \times \frac{v}{a} = 100\,\frac{\frac{s}{d}}{a} = \text{per cent of cu. cm. lost per}$$

sq. cm. of surface. Therefore,

$$K = \frac{p}{\frac{a}{v}}$$

that is, the per cent loss in weight is to be divided by the ratio of surface to volume.

These values of K will then represent the true relative corrodibilities when the conditions of testing are the same except for the densities and dimensions of the specimens. But finally, in order to express in the simplest and most easily comprehended manner the relative values of different materials in regard to their *resistances to corrosion*, the reciprocals of the K values should be taken and compared with, say, the highest one which, for the sake of comparison, may be regarded as having a corrosion resistance of 100 per cent. Thus, if materials A, B, C, and D have values for K of 5, 10, 15, 20, respectively, the reciprocals or resistances to corrosion will be 0.2, 0.1, 0.067, and 0.05, while the relative "efficiencies" of resistance to corrosion will be 100, 50, $33\frac{1}{3}$, and 25, respectively.

This new method of expressing relative corrodibilities takes into account the obvious fact that corrosion varies directly as the exposed surface, other things being equal. The time element cannot be involved in any method of expressing corrosion, for it is a well-established fact that corrosion does not vary directly as the time, since the first layers of corrosion products may in some cases inhibit, and in other cases, accelerate, corrosion. In other words, the duration of all tests that are to yield comparative results should be a constant quantity.

A Series of Comparative Corrosion Tests

It is believed by the writer that careful tests of different sizes of specimens of various kinds of materials run under like conditions will justify the above proposed method of expressing the results, but as yet no such series of tests can be offered. Nevertheless, it may be of interest to report the results of a series of tests that were run for the purpose of ascertaining the consistency of results that could be obtained by exposing small-size specimens to tap water and solutions of sea salt for comparatively short periods of time. These tests are to be regarded as preliminary, and therefore the arbitrary conditions adopted will be subject to such future modifications or drastic changes as inconsistencies in results of these and succeeding series of tests may indicate.

A number of commercial alloys were supplied by various manufacturers who were interested in seeing a series of tests run by experimenters who had no interest in any industrial concern. The analyses of these alloys, as made by the manufacturers, are found in Table 2.

The alloys were supplied in the form of $\frac{3}{4}$-in. rolled stock, which was turned down in a lathe, and from which were cut disks of fairly uniform size. A $\frac{1}{8}$-in. hole was drilled in the center of each specimen in order that a glass hook could be inserted for suspending the specimen in the corroding medium. All the specimens were first roughly polished by emery cloth and then finished to uniform surface conditions by rouge cloth. The disks were then washed in ether to remove all grease, dried in a dessicator, and carefully weighed on analytical balances.

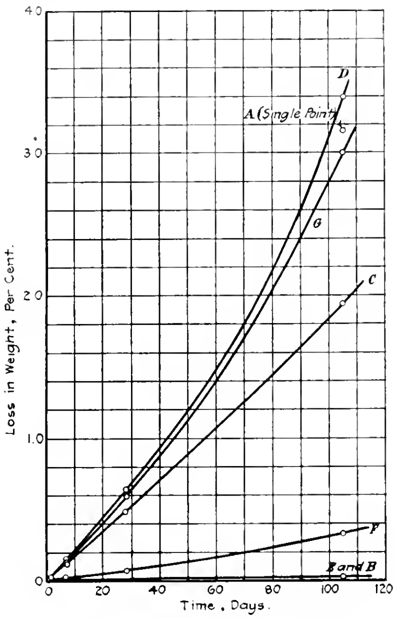

Fig. 1 Corrosion in Tap Water

The following solutions were employed:

1 Tap water
2 0.1 per cent sea-salt solution (one gram of sea salt per liter of tap water)
3 10 per cent sea-salt solution (100 grams of sea salt per liter of tap water).

TABLE 2 ANALYSES OF ALLOYS

	A	B	C	D	E	F	G
				Percentages			
Fe	99 84	2 30	98 473	98 697	Trace	67 405	99 647
C	0 01		0 78	0 479		0 19	0 04
Mn	0 025	$1\frac{1}{2}$–$1\frac{3}{4}$	0 594	0 74		1 35	0 26
Si	0 005		0 065	0 06		0 184	0 01
S	0 025		0 055	0 035		S and P less than 0 04	0 036
P	0 005		0 013	0 009			0 007

Ni	.	65 48				30 83	...
Al	.				9 96		.
Ti			0 02	.			

The tests on the various alloys and three solutions were run simultaneously with duplicate specimens. A 150-c.c. beaker filled with 100 c.c. of the corroding solution was provided for each individual specimen, which was suspended in the middle

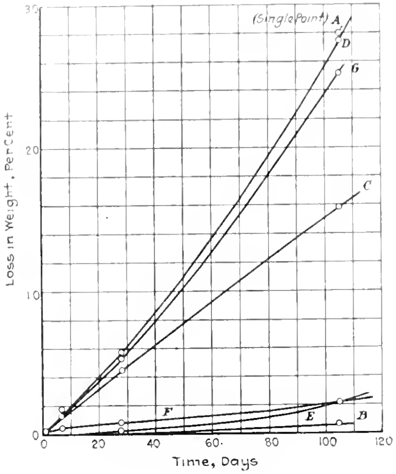

FIG. 2 CORROSION IN 0.10 PER CENT SEA-SALT SOLUTION

of the solution by means of a glass hook attached to a short piece of wood resting on top of the beaker. At the end of the one-day (24-hour) test the specimens were removed from the beakers, soaked for several hours in a solution of ammonium citrate in order to remove the rust, dried and carefully weighed to determine the loss in weight. The specimens were then polished so as to have new surfaces, cleaned, dried and weighed for the succeeding seven-day test, for which new solutions were employed. This procedure was maintained for

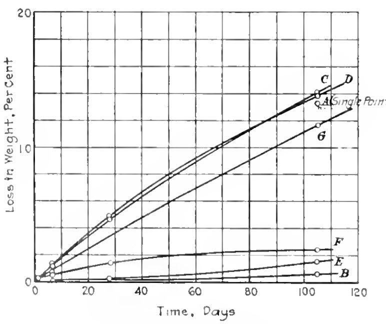

FIG. 3 CORROSION IN 10 PER CENT SEA-SALT SOLUTION

the 28- and 105-day tests. In all cases the beakers were placed in a glass case, and the daily maximum and minimum temperatures were observed.

RESULTS

In expressing the results of these tests, the percentages of loss by weight were plotted in Figs. 1, 2 and 3, rather than the values of K as proposed above, for the reason that the ratios of the surface to volume were practically the same, the average deviation from the mean being only 4.6 per cent. In Figs. 4, 5 and 6 are plotted the relative efficiencies of resistance to corrosion as previously explained in this paper, the alloy marked F being taken as the 100 per cent standard in this case. Alloys B and E exhibited such a slight amount of corrosion that they could not very well be used as a basis for comparison.

Among the points to be noted as a result of these tests are the following:

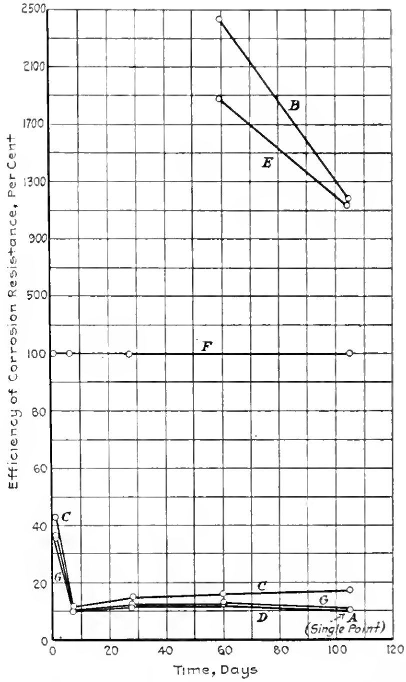

FIG. 4 RELATIVE EFFICIENCIES OF CORROSION RESISTANCE IN TAP WATER

1 The most impressive feature as seen in the curves of Figs. 1, 2 and 3 is the consistent grouping of the more corrosive iron and steel alloys A, C, D, and G, as against the highly resistant alloys B, E and F, in which copper and nickel are the most prominent constitutents. In the first group it should be noted that the steel C, in which titanium is employed as a cleanser, shows considerably less corrosion than the other steels in tap water and weak salt colutions. In the second group the copper-nickel alloy B was in most cases superior and in no case inferior to all the other alloys. This was the only alloy that exhibited its original appearance after being cleaned in the ammonium citrate solution.

2 Perhaps the next most impressive fact brought out by these tests is the decreased corrosion of the more corrosive group of alloys as sea salt is added to tap water. This effect is not observed in the non-corrosive group of alloys, for the reason that it is probably masked by experimental errors in determining the very slight losses in weight. This decreased corrosion with increased concentration of the salt solution is

in harmony with the results of other experimenters, notably Friend and Barnet.[1]

3 The practically pure iron *A*, which was received in time for only the 105-day test, gave very disappointing results, since in all three corroding media it showed practically the same corrosion as the ordinary carbon steels, *D* and *G*. However, in fairness it should be pointed out that rust may either accelerate or inhibit corrosion. If the metal is homogeneous, sound, dense, and free from occluded gases, the rust will probably be dense and closely adherent and will thus offer some degree of protection. If the metal is non-homogeneous and contains a considerable amount of occluded gases, the latter upon escaping will cause the rust to become spongy and porous, and will therefore permit the electrolyte to come more readily into contact with the metal. In the case of the practically pure iron *A* only one test (105 days long) was run, and consequently no curve of results could be obtained.

4 A study of the data points to the conclusion that when corrosion specimens are fairly uniform in density, area of exposed surface and volume, the method of expressing the relative corrosions by per cent loss in weight gives results as consistent as those obtained by the newly proposed method, for the average deviations of both methods are practically equal. It should be kept in mind, however, that the use of the new method, in cases where the specimens vary considerably among themselves with regard to density or ratio of surface to volume, will serve to give a much better basis for comparison than any other method.

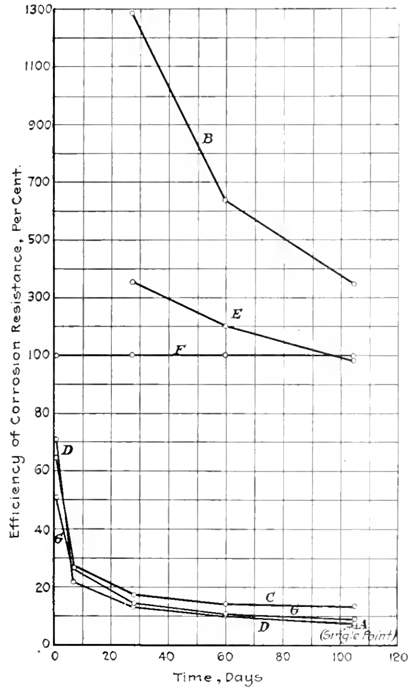

Fig. 5 Relative Efficiencies of Corrosion Resistance in 0.10 Per Cent Sea-Salt Solution

5 The relative efficiencies of corrosion resistance as shown graphically by Figs. 4, 5 and 6 indicate that very consistent results can be obtained by the method of testing employed in these series, when the duration of the test is one week or more for the more corrosive alloys and about two months or more for the less corrosive alloys. In fact, one day is quite sufficient to classify groups of alloys in the order of their corrodibility for such corroding media as will cause enough loss in weight to be determined by analytical balances. Nevertheless, before any final conclusion can be drawn as to the best method of testing relative corrosion, a vast amount of work will have to be done, especially with reference to the results of service tests as compared with laboratory tests similar to those described in this article. For the present, however, it seems proper to conclude that very consistent results (at least among themselves) can be obtained by using small specimens and employing refined methods, but without using "accelerating" conditions.

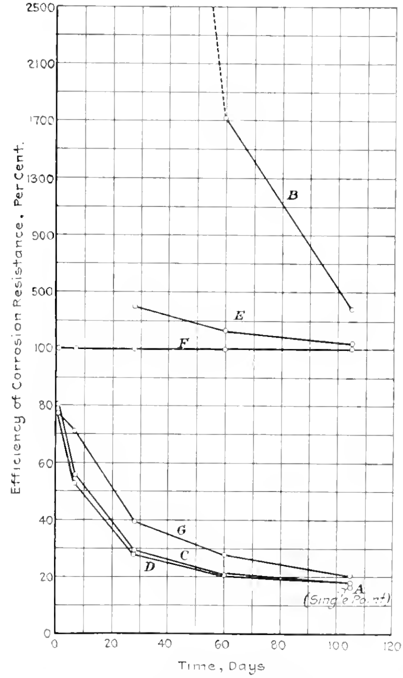

Fig. 6 Relative Efficiencies of Corrosion Resistance in 10 Per Cent Sea-Salt Solution

Acknowledgment

The writer wishes to record his appreciation of the assistance and coöperation of Dr. J. P. Jackson, formerly Dean, and of Prof. R. L. Sackett, the present Dean of the School of Engineering; to Prof. J. A. Moyer, and to Prof. M. M. Garver. He also desires to acknowledge the services rendered by M. P. Helman and G. S. Long, who prepared the specimens and obtained much of the data; and by E. F. Grundhoeffer, who, with the assistance of A. A. Bawiec and L. S. Longenecker, made most of the calculations and drew the curves.

RECOVERY OF GASOLINE FROM CASING-HEAD AND NATURAL GAS

By PAUL DISERENS,[1] CINCINNATI, OHIO

CASING-HEAD gasoline is gasoline which passes off in the form of vapor with natural gas accompanying the flow of an oil well, where oil and gas are found in the same field. In many localities this gas is wasted because of the difficulty of handling it, or because no market exists for its sale, due to its relatively small volume. Often, however, the recoverable gasoline in the gas is worth as much as 20 per cent of the oil produced.

The practice of pumping casing-head gas to develop a vacuum on the well and thus to stimulate the flow of oil is, at this time, rapidly increasing and it is where this is done that plants for the recovery of casing-head gasoline are most profitable. In some fields, particularly California and Wyoming, gas is handled which comes directly from the wells under rock pressure or where the gas comes directly from gas wells. Such gas, however, yields relatively small quantities of gasoline.

TABLE 1 VAPOR PRESSURES AND CORRESPONDING TEMPERATURES AT WHICH CERTAIN HYDROCARBONS WILL CONDENSE

Temperature, Deg Fahr.	Vapor Pressure, Lb. per Sq. In.				
	Propane C_3H_8	Butane C_4H_{10}	Pentane C_5H_{12}	Hexane C_6H_{14}	Heptane C_7H_{16}
32	72.5	15.9	3.5	0.9	0.2

90	165.0	53.2	11.9	3.2	1.1

The process most used in the recovery of casing-head gasoline is a physical one and involves only the alternate compression and cooling of the gas. As already stated, it will be understood that gasoline in the form of vapor constitutes part of the gas as it comes from the well or casing head. If the gas were saturated, gasoline would be immediately precipitated when compressed, provided it could be kept at a constant temperature, but since the heat of compression increases its temperature, the gasoline is still retained as vapor. When it is cooled, however, gasoline is thrown down in the form of condensate, and if the gas is cooled to its original temperature the gasoline still retained in it as vapor will only be in the proportion of its initial and final volume, or very approximately so. Since there are always present a great number of condensable fractions, each a different hydrocarbon of the paraffin series, the precipitate of each depends upon the partial pressure of each.

The vapor pressures at which some of the hydrocarbons of the paraffin series constituting casing-head gas will condense for various temperatures are shown in Table 1. It is never practical to determine exactly which of these hydrocarbons occur in the particular casing-head gas to be handled, or in what proportions they are found. It is not possible, therefore, to predict what total pressure it will be best to carry. Generally, however, it is found advisable to carry not less than 250 lb. and it seldom is profitable to carry more than 300 lb.

The application of the principle as briefly stated requires the installation of a two-stage gas compressor with suitable intercooler and aftercooler. Vacuum pumps for bringing the gas from the wells to the plant are also required. The intercooler and aftercooler are of the open-coil type, and assuming that the surface available is large, the efficiency attainable depends upon the temperature of the cooling water. It is of great importance, therefore, to make provision for an ample supply of water. For this purpose cooling towers are generally provided, since in most oil fields fresh water is obtainable only in limited quantities. With cooling towers, even of the best design, it is impossible to attain low temperature during the hot weather, which prevails during a large part of the year. As a means, therefore, of supplying additional cooling effect, an expander refrigerator is installed, the function of which is to reduce further the temperature of the gas itself after having passed through the cooling coils. It consists of a cross-compound expansion engine driving a gas compressor. The compressed gas coming from the aftercooler is used in this expansion engine, and because of the work done in its cylinders is expanded adiabatically, or, in other words, in such a manner as to reduce its temperature. The cold gas is then returned through double pipe coils where its refrigerating effect is utilized to further cool the compressed gas. The amount of refrigeration thus available is in direct proportion to the amount of work done in the compression cylinders driven by the expander, and is proportioned to the total number of expansions; that is, to the ratio between its initial and final pressure, provided, of course, the cylinders of the expander are properly proportioned. The expander produces this refrigeration without the expenditure of additional power, and the energy in the compressed gas, which otherwise would of necessity be wasted, is available for useful work in compressing additional gas used in the process.

Fig. 1 shows a plan and elevation of a gasoline plant. The gas is delivered by means of vacuum pumps, reference to which will be made later, to the tank *A*, where such gasoline as will be precipitated under ordinary conditions of temperature and atmospheric pressure or even slight vacuum is collected. The suction line to the low-pressure compressor is taken from the top of the so-called drip tank and leads to the low-pressure compressor *F*, where it is compressed to approximately 40 lb. gage pressure. It is then delivered to the cooling coils *C*. The condensation collected in these coils is drawn off through a trap and the dry gas returned to the suction of the high-pressure compressor *E*, where it is compressed to about 250 lb. and again passed through cooling coils *G*. The condensed gasoline in these coils is also removed by means of a trap and delivered to suitable storage tanks.

The original design of the plant as shown provided for the expansion of the compressed gas through a so-called Tripler tube *D*. This tube is similar in design to the ordinary double-pipe ammonia coil, the expanded gas passing around

[1] Engineer, Worthington Pump and Machinery Corporation. Mem. Am Soc.M.E.

Abstract of paper presented at a joint meeting of the Associated Engineering Societies of St. Louis, under the auspices of the St. Louis Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, January 16, 1918.

and surrounding the internal tube through which the compressed gas from the high stage is passed. The expansion of the high-pressure gas in this tube brings about a temperature reduction of the high-pressure gas and additional gasoline is precipitated. The impossibility of expanding gas adiabatically through a nozzle is well understood and for this reason it never has been possible to effect any great temperature reduction in this Tripler tube. As long as the expanded gas retains its high velocity the temperature is relatively low, but as soon as it comes to rest it rises very rapidly.

When the high-pressure gas expanded through the reducing valve in the Tripler tube contains appreciable quantities of gasoline in the form of mist rather than as a vapor, a considerable amount of cooling will be realized when this gasoline flashes into vapor as soon as the reduction in pressure takes place. This is explained, of course, by the fact that the heat of vaporization must come from the gas which carries the gasoline. A well-designed plant, however, should be equipped with accumulator tanks of sufficient size to separate practically all entrained liquid, and if this is done, the high-pressure gas will be practically dry when it reaches the expansion valve. Thus, if considerable refrigeration is actually brought about in the Tripler tube, it only signifies that the design of the plant is faulty. By the use of a Tripler tube some of this loss may be recovered in shape of refrigeration. The net result, however, will be a definite loss.

In order to bring about a greater temperature reduction through the expansion of this high-pressure gas, an expander compressor was installed. In the plant shown, a small single-stage expander was installed after the plant as just described was put in operation. The high-pressure gas after passing through the double pipe coil is admitted to the expansion cylinder of the expander compressor at approximately 250 lb. pressure and is exhausted against a back pressure of 15 to 20 lb. through the collecting tank B, and thence through the outside of the double pipe coil D, where it serves to cool the compressed gas within the inner tubes. The power developed in the expansion engine is used to compress additional gas, and this gas is delivered to the same intercooler and aftercooler, C and G, used by the main compressors.

The general piping arrangement in the plan as shown is rather crude, but is fairly representative of most plants which have been in operation for two or three years. In some of the more modern plants a much more convenient and flexible arrangement will be found.

Even with a single-stage expander as installed in this plant, a very great increase in the yield of gasoline has resulted.

The successful operation of this small single-stage expander was not easily accomplished. The collection of ice around the valves, together with the difficulty of lubricating them, made necessary numerous shutdowns. It was soon found, however, that by using glycerine in very small quantities as a lubricant and by applying this directly to the rubbing surfaces, the machine could be operated almost continuously. Whenever it was possible to reduce the temperature of the compressed gas approximately to the freezing point, all water vapor contained in it was frozen and thus removed before entering the expander. In very warm weather the amount of refrigeration available was not sufficient to bring about so great a temperature reduction, and at these times, after continued operation, the ice collecting in the exhaust ports and in the valve chest seriously interfered with its operation. It was found necessary to thaw out the expander at regular intervals, generally once in 24 hours. For this purpose a bypass pipe leading directly from the high pressure compressor was used to bring high-pressure gas, before being

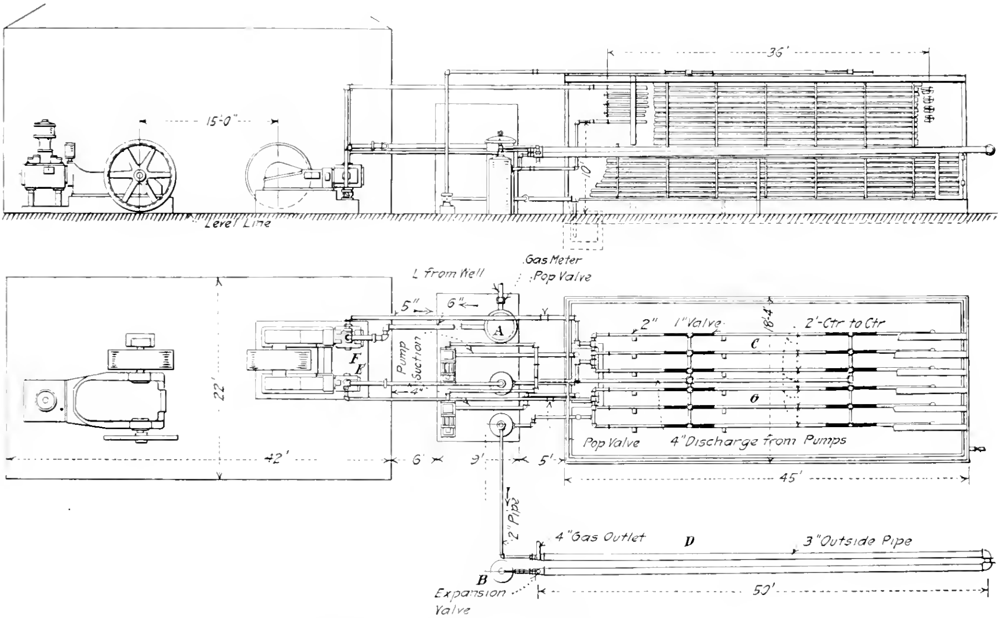

Fig. 1 Plan and Elevation of Feather Valve Compressor

cooled by the water coils, directly to the expansion cylinder. The temperature of this gas was sufficient to thaw out the ports in a very short time.

In order to overcome to a certain extent many of these difficulties in operation and in order to secure considerably lower temperatures, the expander compressor is now made a cross-compound machine. It is possible, therefore, to carry the expansion much further and to reduce the temperature of the gas to a far greater extent.

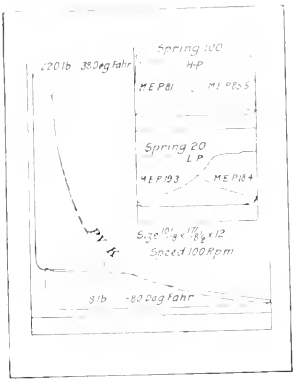

FIG. 2 TYPICAL INDICATOR CARDS FROM EXPANSION CYLINDERS OF GAS EXPANDER

No insulating material was used in this installation, and therefore the very low temperatures obtained were shown in a very spectacular manner. Frost and ice cover the cylinders and exhaust pipes to a depth of 6 to 10 in. The machine has expansion cylinders 10 in. and 18 in. in diameter with compression cylinders 17 in. and 8½ in. in diameter, respectively; the stroke is 12 in. Indicator cards taken from the expansion cylinders (Fig. 2) show the performance of this machine. These cards are of particular interest. It will be seen that the expansion line follows very closely an equilateral hyperbola and therefore is not nearly so steep as the adiabatic, as might be expected. The explanation, however, is quite evident, since the gas handled is not a dry gas but is in fact a mixture of dry gas and numerous condensable vapors of the various hydrocarbons referred to above. As soon as this mixture enters the cylinder and comes in contact with the very cold walls and ports, initial condensation takes place and as expansion proceeds, reëxpansion occurs exactly as in the case of the steam engine. The initial condensation, however, is very much greater and it is necessary to provide suitable drains in both cylinders to take care of the gasoline thus precipitated.

The initial temperature of the gas entering the high-pressure expansion cylinder in the plant in which these cards were taken, averaged about 38 deg. fahr., while the temperature at the exhaust of the low-pressure expansion cylinder was 80 deg. below zero. The temperature of the high-pressure gas before entering the double pipe coils, through which the exhaust gas from the expander is taken, was 90 deg. If there had been no condensation in the expander cylinders and if the interchange of heat within the double pipe coils had been accomplished without loss by radiation, the final temperature of 80 deg. below zero should have been sufficient to reduce the temperature of the incoming gas to zero instead of 38 deg. above zero, since the compressed and expanded gas are of the same weight.

In order to bring about more complete interchange of heat and in order to limit initial condensation, in one of the most recent installations the two-stage expander was arranged so as to exhaust first from the high-pressure expander cylinder through a set of double pipe coils and then after further expansion in the low-pressure cylinder through another set of double pipe coils. By this means the range of temperature is, of course, greatly reduced and because of this fact there is considerably less initial condensation and, therefore, a greater interchange of heat. The general arrangement for such an installation is shown in Fig. 3.

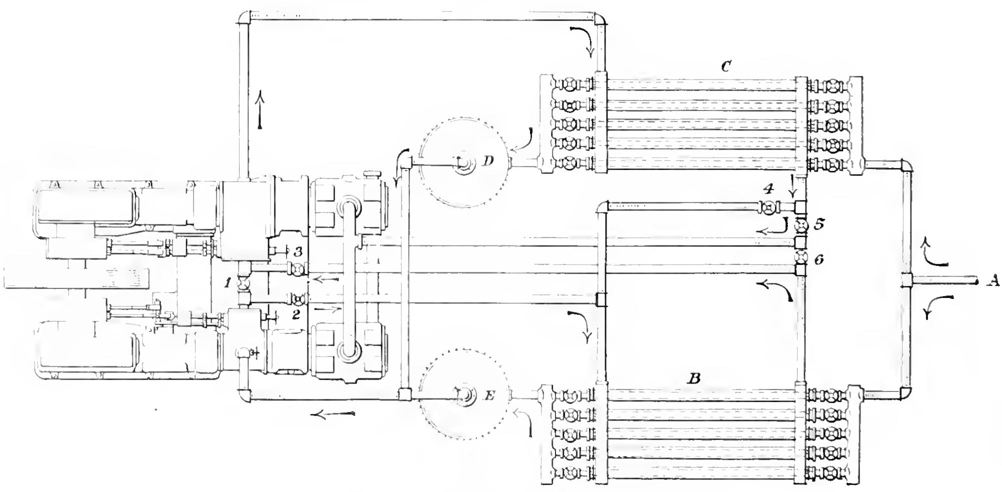

FIG. 3 HEAT EXCHANGER FOR TWO-STAGE EXPANDER

The practical operation of these two-stage expanders is

considerably simpler than that of the single-stage expanders originally installed. The reason is, of course, because of the considerably greater refrigerating effect obtained. In many plants it is easily possible to operate the expander continuously for indefinite periods, but in particularly warm climates and where the gas is very rich in condensable vapors, the temperatures even with a two-stage machine are not sufficiently low to prevent accumulation of ice within the cylinders. By using hot gas at regular intervals to thaw out the pipes, these plants can be operated very successfully.

Next to the expander the vacuum pump is, perhaps, the most interesting apparatus used in a gasoline plant. When the production of relatively old wells begins to fall off, it has been found that the flow of oil can be very materially increased by developing a vacuum in the casing. Until recently this was done by attaching a rather crude direct-acting pump directly to the rigging of the well. With a pump of this kind it is seldom possible to develop a vacuum of more than 10 in. to 12 in. of mercury. Competition between owners of adjoining leases to carry the highest possible vacuum, in order to get their full share of the oil, has recently brought about a demand for vacuum pumps of much greater efficiency, and so within the last few years a great number of high-speed, high-efficiency vacuum pumps driven by gas engines have been installed.

While there are now on the market two or three vacuum pumps of relatively high efficiency, the newest and perhaps the most novel in design is found in the Laidlaw feather-valve vacuum pump. Its construction and performance will therefore be of interest.

This vacuum pump depends for high efficiency upon close clearance and its distinguishing feature is found in the use of voluntary valves of the feather type. Each valve consists of a number of thin, flexible strips of spring steel, working on a flat seat and opening against a slotted guard. The ends of the valves never leave the valve seat, the opening being accomplished by continuous bending of the valve strip itself. The valve, therefore, in closing, seats through gradual contact from the ends of the valve toward the center and not by direct impact. This makes it possible to give the valve a relatively high lift and consequently relatively large valve area. Because of the extreme flexibility of the valve strips used, even the very light pressures incident to vacuum-pump work are sufficient to hold the valve to the seat with extreme tightness.

A vacuum pump of this type can easily develop a vacuum on closed suction of 29½ in. of mercury, or in other words, within ½ in. of the barometer. This, of course, determines the volumetric efficiency of the vacuum pump at any working vacuum, for assuming that the volumetric loss in a vacuum pump is directly proportional to the number of compressions under any working conditions, the volumetric loss will be the ratio of this number of compressions to that obtained with the pump working on a closed suction, since under this condition of operation the volumetric efficiency will be zero, in other words, when the volumetric loss exactly equals the capacity of the pump. With this assumption it is possible to express algebraically the actual capacity of any vacuum pump for any given working condition. For example, the actual capacity of a vacuum pump having a displacement of D cu. ft. per min. that will deliver Q cu. ft. of free gas per 24 hours, is expressed in the following formula: $Q = 1440\ D \times (C - V)/B$, where B is the barometric pressure, V the actual working vacuum and C the vacuum developed on closed suction. The relationship thus defined gives a very simple means of determining the size of pump required for any particular service, for it is only necessary to know the amount of gas available, the vacuum at which it is to be handled and the vacuum which the pump will develop with its suction closed.

In order to facilitate the choice of a pump for any particular service, the chart shown in Fig. 4 will be useful. This

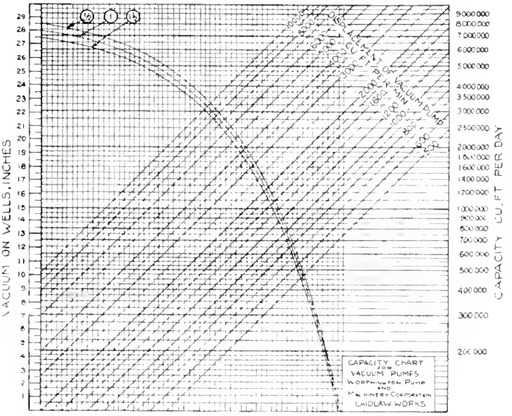

Fig. 4 Capacity Chart for Vacuum Pumps

chart shows the capacity of vacuum pumps having any displacement ranging from 500 cu. ft. per min. to 10,000 cu. ft. per min. and working under any degree of vacuum up to 28½ in. of mercury, referred to a barometer reading of 29½ in. On this chart are shown three efficiency lines, corresponding to pumps capable of maintaining ½, 1 and 1½ in. of mercury absolute on a closed suction.

The use of this chart is illustrated by the following example: If it is required to select a pump capable of handling 500,000 cu. ft. of free gas per day at 21 in. of vacuum, proceed as follows: Select the horizontal line marked "21 inches" at the left of the diagram; follow this line in a horizontal direction to its intersection with the curved efficiency line marked "one-half inch." On the vertical line passing through this intersection, proceed vertically until the horizontal line marked 500,000 on the extreme right of the diagram is reached. The diagonal line passing through this intersection represents the displacement in cubic feet per minute of the vacuum pump, which will give the required service. It will be seen in the example selected that the vacuum pump must have a displacement of 1200 cu. ft. per min.

The results of a test on one of these vacuum pumps to determine its actual volumetric efficiency are shown in this diagram. The quantity of air handled was measured by means of a low-pressure orifice, using Professor Durley's coefficients; the results are plotted as volumetric efficiency for various working vacua. The heavy line shown in this diagram represents the volumetric efficiency calculated from the chart already shown. The actual test results coincide with a fair degree of accuracy with those estimated from the chart.

Another method of recovering gasoline from natural gas or casing-head gas is by what is known as the absorption process. This process is used primarily where the gas treated is lean, that is, when its gasoline content is small.

In the absorption process the wet gas, together with the absorbing oil (usually mineral-seal or straw oil), is forced

under pressure into the absorber where the two come into intimate contact, the proportions of gas and oil being so controlled that the oil, when leaving the absorber, will be approximately saturated with condensable vapor from the gas. On leaving the absorber the saturated oil is passed through suitable heat interchangers, where its temperature is raised by means of hot return oil from the still. The hot saturated oil is then led to the still, where additional heat is applied, and the gasoline

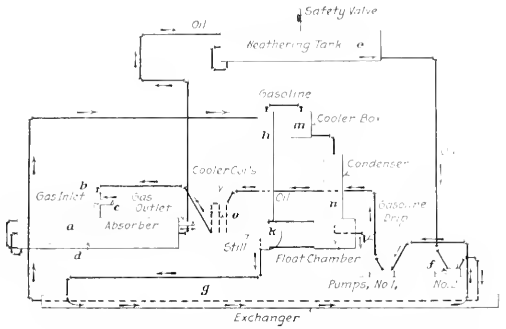

FIG. 5 GENERAL ARRANGEMENT OF SMALL GASOLINE ABSORPTION PLANT (BULLETIN 120, BUREAU OF MINES)

driven off in the form of vapor. These gasoline vapors are condensed in water-cooled coils and delivered to suitable blending and storage tanks. The residue-absorbing oil is then returned to the heat interchanger, where it gives up a great part of its heat to fresh saturated oil, as described above, after which it is passed through a cooler similar in design to the water-cooler coils of the compression plant, where its temperature is reduced to the lowest possible point. After cooling the oil is returned directly to the absorber. It will be seen that the process is a continuous one, and that the absorbing oil is used over and over again.

Fig. 5 shows diagramatically the general arrangement of a small absorption plant. The natural gas, which is brought in from a pipe line under pressure, enters the absorbing tank

tower h of the steam still k, where the gasoline is distilled from the oil with live steam. The cooler m separates the water (condensed steam) from the gasoline, which is condensed in the condenser and flows out of the system at the gasoline drip.

The hot oil after having been freed of its gasoline is pressed through the heat exchanger g and heats the oil passing to the still and from No. 1 pump it is forced through the cooling coils o, on which running water drops. The cooled oil then passes into the absorber a to receive another charge of gasoline.

In the absorption method it will be seen that a very considerable amount of gas must be burned under boilers to generate sufficient steam to operate the steam stills. Since in nearly every instance absorption plants are installed as an adjunct to a gas-pumping station used to supply gas for domestic service, the diversion of any considerable amount of gas to operate boilers instead of pumping it through the mains where it has a market value of probably 30 or 40 cents per 1000 cu. ft., operates to greatly reduce the profits to be derived from the gasoline plant. Any system, therefore, which will do away with the necessity of separating the gasoline from the absorbing oil by means of steam stills is greatly to be desired. While as yet no such plants have been installed, a very interesting solution of the problem has been proposed in a combination of the absorption and compression processes. The plan contemplates the absorption of the gasoline in the usual way, as already described, and then introducing the resulting blend of absorbing oil and gasoline into a closed vessel in which a high vacuum is maintained. The gasoline will, of course, immediately volatilize, and may be removed by means of vacuum pumps, passed through cooling coils and condensed.

The general arrangement of such a plant is shown in Fig. 6. It will be seen that it consists of three elements, an evaporator, a vacuum pump, and a bank of cooling coils with suitable accumulator tank. The saturated oil from the absorbers is pumped into the evaporator through spray nozzles which deliver it in a finely divided mist. Because of its relatively low boiling point the gasoline must of course come from the absorbing liquid, and thus the process brings about a refrigerating effect and the oil itself is cooled. This is an item of extreme importance, since the oil upon its return to the ab-

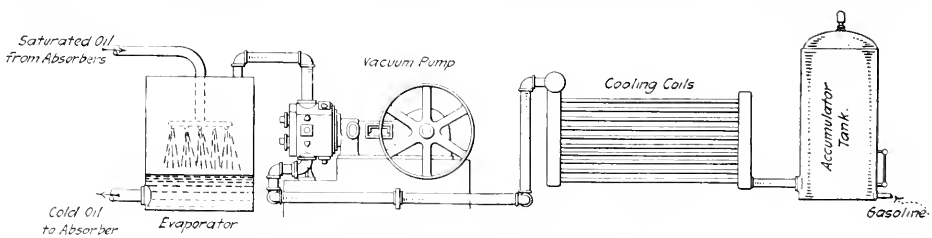

FIG. 6 COMBINED ABSORPTION AND COMPRESSION PLANT

at e and the oil enters at b. They pass into the T-pipe d, and the mixture passes from there through many small holes into the oil contained in the absorber. The gas bubbles up through the oil and passes out of the absorber as shown and returns to the pipe line.

The oil charged with gasoline passes first to the weathering tank e, where the lighter parts of the gasoline are released through the safety valve. Next the oil enters the pump f and is pumped through the heat exchanger g into the rock

sorbers will be at a temperature low enough to bring about most effective absorption. In the ordinary absorption plant the principal factor which limits its efficiency is this temperature, and great pains are always taken to keep it as low as possible. The vacuum pump serves not only to maintain the required vacuum within the evaporator, but also to remove the gasoline vapors. These are delivered to the cooling coils, which may be in every way similar to those used in the compression process.

THE INCOME TAX—AN ENGINEER'S ANALYSIS

By CARL G. BARTH,[1] PHILADELPHIA, PA.

In view of the revenue bill now pending before Congress, involving a revision of the present income-tax law, a paper presented by Carl G. Barth at the February 26, 1918, meeting of the Philadelphia Section of The American Society of Mechanical Engineers is of timely interest.

In a telegram from Washington, published by the Chicago *Herald* in August 1917, which gave the status at that time, in the Senate Finance Committee, of the personal income-tax law, Mr. Barth observed that reference was made only to the incomes to be taxed at various rates, and being impressed with the lack of regularity in the increases at which incomes were taxed with increasing tax rates, as well as in the tax rates themselves, he decided, inasmuch as the term "graded or graduated tax" seemed to imply a tax or tax rate that would gradually increase with increase of income, to investigate the matter mathematically in the same way he was accustomed to deal with practical engineering problems, leaving to others the consideration of its broader financial and economic aspects. It appeared to him that the framers of the law, having had in mind to devise a scale of tax rates increasing in proportion to the incomes to which they were applied—a problem altogether mathematical, since it involved the determination of a series of numbers—had nevertheless selected a scheme of graded taxation with arbitrary steps of percentages.

Two of the results of Mr. Barth's investigations are presented below—his analysis of the present law by comparison with an approximate mathematical expression which may be said to represent the intention of the law, and the general formula he recommends as suitable and convenient for the determination of a graded tax.

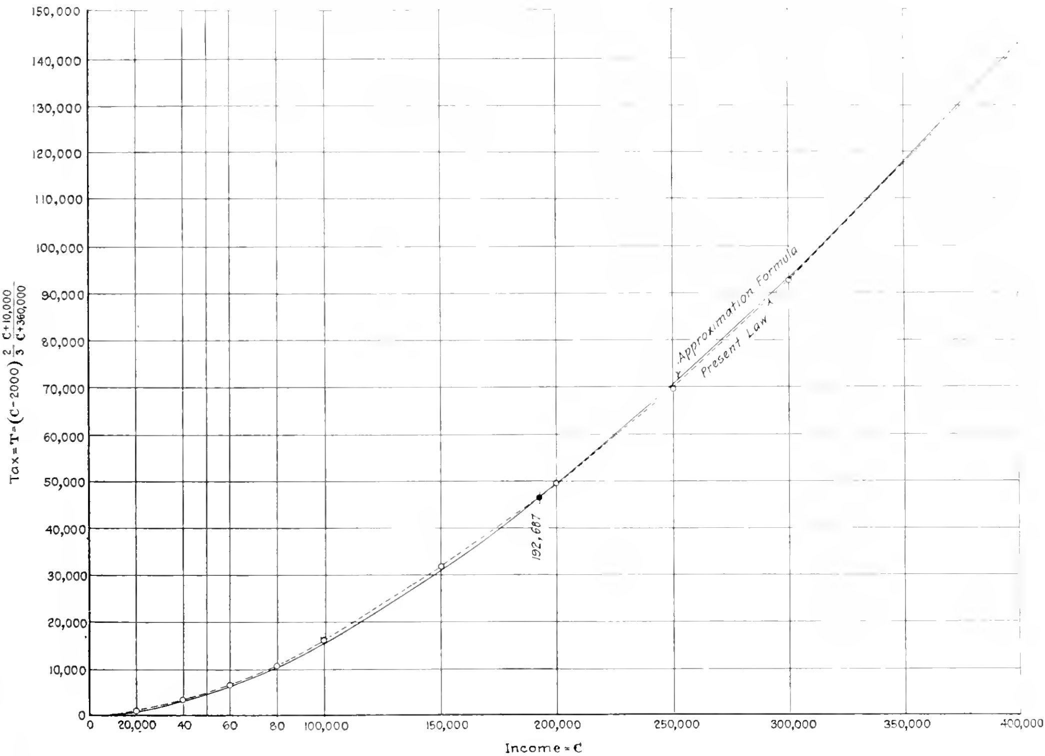

Fig. 1 Comparison of the Income Tax Law as Represented by the Dotted Line, With Its Approximation Formula [1] as Represented by the Full-Line Curve

The empirical formula

$$T = (C - 2000) \cdot \tfrac{2}{3} \cdot \frac{C + 10{,}000}{C + 360{,}000} \quad \ldots\ldots\ldots\ldots [1]$$

according to Mr. Barth, expresses very closely the relation between the net taxable income C and the tax T as determined for married men by the present law.

The equation of the full-line curve in Fig. 1 is Formula [1].

[1] Senior member, Carl G. Barth & Son. Mem.Am.Soc.M.E.

The paper is here presented in abstract. The complete paper has been reprinted in pamphlet form by The Engineers' Club of Philadelphia.

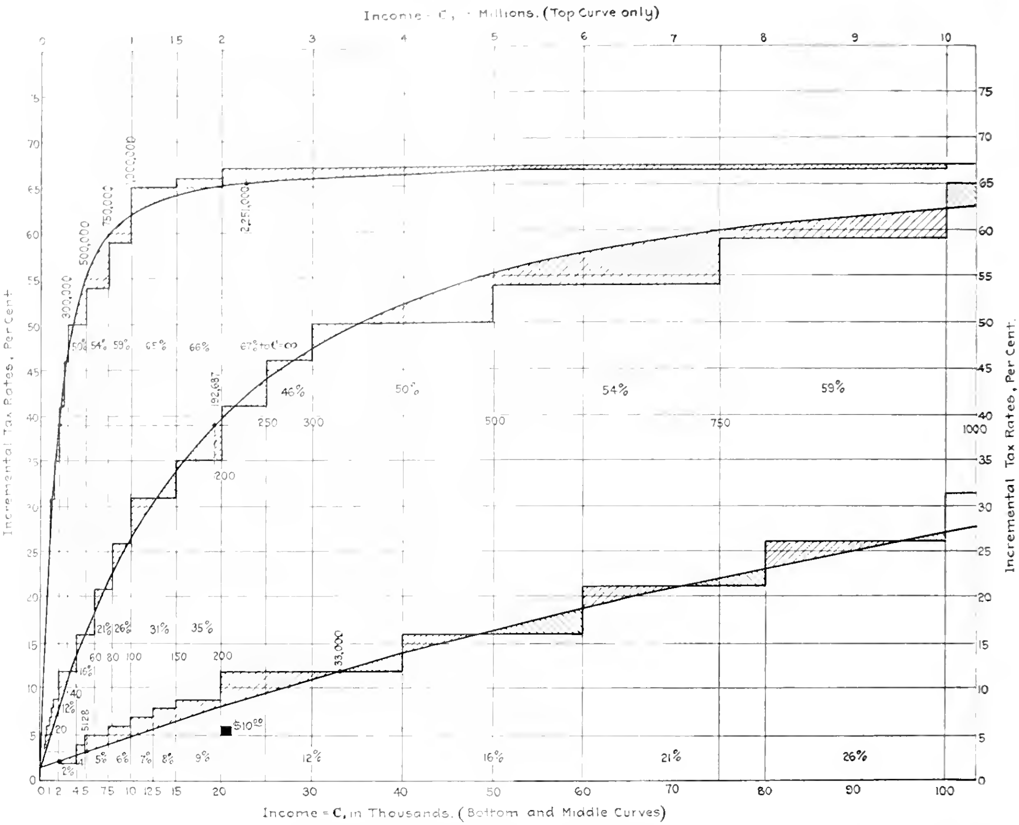

FIG. 2 GRAPHICAL REPRESENTATION OF THE DISCREPANCIES BETWEEN THE INCOME TAX LAW AND FORMULA [1]. THE SHADED AREAS ABOVE THE SMOOTH CURVE INDICATE FIELDS OF OVERTAXATION; THOSE BELOW, FIELDS OF UNDERTAXATION

The dotted line was obtained by drawing a smooth curve through the points marked with a circle, the coördinates of these points representing corresponding values of income and tax as determined by the present law.

A more conspicuous comparison of the law and the formula is shown in Fig. 2, where the bottom field covers incomes up to \$100,000, on a comparatively large scale; the middle field, incomes up to \$1,000,000, on a scale equal to one-tenth of the former; and, finally, the top field, incomes up to \$10,000,000, on a scale equal to one one-hundredth of that of the bottom field; while in all three fields the scale is the same for the percentage of tax levied in the various fields of incomes.

In the main bottom field of Fig. 2 at the income \$2000 where taxation begins at 2 per cent, the \$40 of tax between 0 and \$4000 is represented by the little rectangle in which 2 per cent is written, such that half of this rectangle similarly represents the tax up to \$3000. Similarly, the rectangle between the incomes \$4000 and \$5000, the upper part of which is shaded and in which four is written, represents tax on \$1000 at 4 per cent, or an additional \$40. Again, the rectangle between the incomes \$5000 and \$7500, the upper part of which is also shaded and in which 5 is written, represents a further additional tax on \$2500 at 5 per cent, or \$125, and so on through the whole diagram, such that the total area covered by all the rectangles from the income \$2000 up to any other income, represents the total tax on such latter income. The curve, the area between which and the upper limit of each rectangle is shaded, represents the gradually increasing tax rate that corresponds to Formula [1].

That area between the base line of the diagram and this curve which lies between any two incomes, accordingly represents that tax between these incomes which is called for by the formula. The shaded areas that lie above the curve represent the overtaxation of the law in the various fields, while the shaded areas that lie below the curve similarly represent the undertaxation of the law, such that, when once understood, the diagram most clearly and conclusively demonstrates not only the lack of continuity, but also the lack of regularity in the attempted compromises in the present law. It also most clearly shows that there is a relative undertaxation from \$2000 up to \$4000, and relative overtaxation all the way from \$4000 to \$33,000, such that the undertaxation below \$4000 is exactly balanced by the overtaxation between \$4000 and \$5128. Between \$33,000 and \$192,687 over- and undertaxation so alternate, with the excess undertaxation so great between \$150,000 and \$192,687 that at this latter income the net result is again

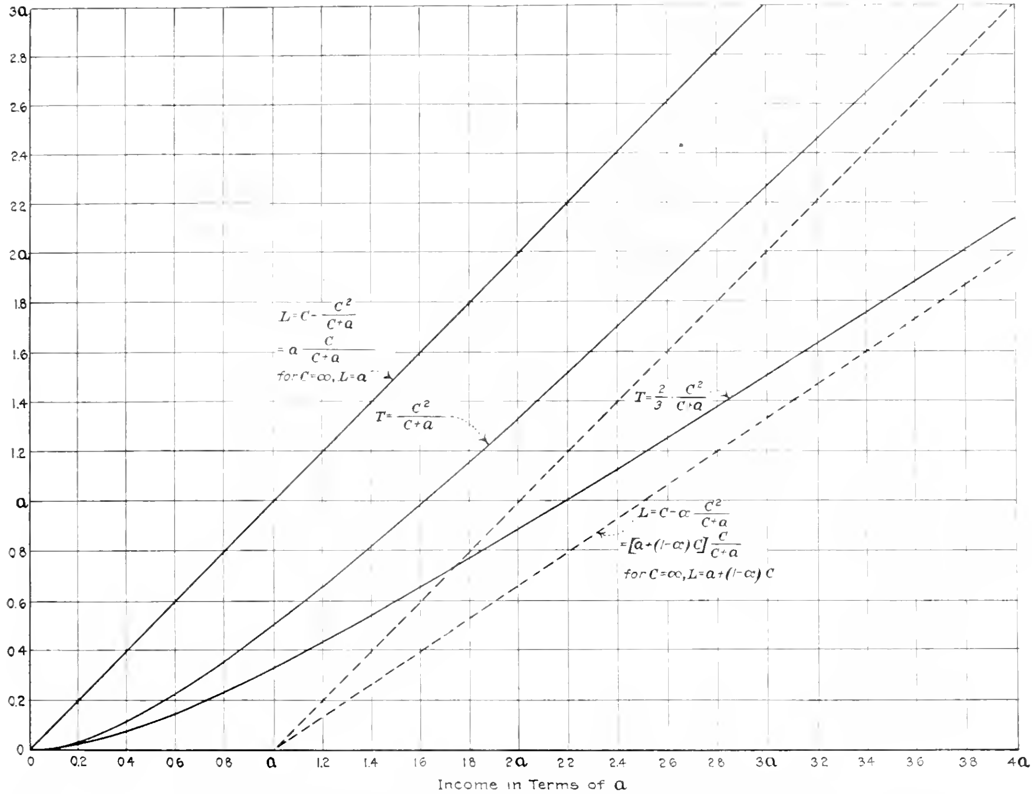

FIG. 3 GRAPHICAL REPRESENTATION OF FORMULÆ [2] AND [4]. UPPER FULL-LINE CURVE CORRESPONDS TO FORMULA [2] FOR $\alpha = 1$; LOWER FULL-LINE CURVE, TO THE SAME FORMULA FOR $\alpha = 2/3$

a coincidence with the formula. Between \$192,687 and \$350,000 the alternating undertaxation and overtaxation will be seen to balance each other pretty well; but from \$350,000 up to \$1,000,000 the whole field will be seen to be undertaxed to an extent that amounts to a veritable discrimination in favor of all incomes between these limits.

From his discussion of Fig. 2, Mr. Barth concludes that a scheme of graded taxation with definite steps of percentages is subject to unavoidable minor injustices, and that full relative justice can be meted out only by taxing according to a continuous formula. He proposes, therefore, for any scheme of graded taxation, the adoption of the general formula

$$T = \alpha \frac{C^2}{C+a} \quad \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

where T is the tax, C the income, and α and a are constants to be determined from the fundamental economic and social conditions of the country. His discussion of the possibilities of this general Formula [2], according to the values given to the coefficients α and a, follows:

If α is made 1, the formula becomes

$$T = \frac{C^2}{C+a} \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

and in this form it may be considered as representing an ultimate limit in a graduated-taxation scheme, and as such must be fully understood and consulted before a rational selection can be made of values for either α or a in Formula [2].

In Fig. 3, Formula [3] is represented by the upper curve against which any income and its corresponding tax are read in terms of a. The upper, full line, being at an angle of 45 deg., reads an income against the vertical scale as well as against the horizontal scale, so that the vertical distance between this line and the curve represents the difference between an income and its tax, or what is left the taxpayer; and this amount more and more approaches the value a, which is the constant vertical distance between the full 45-deg. line and the dotted 45-deg. line which parallels it. Designating what is left the taxpayer by L, this amount may be written

$$L = C - T = C - \frac{C^2}{C+a} = \frac{aC}{C+a} = a\frac{C}{C+a}$$

which, as C gradually becomes greater and greater, approaches the value a as a limit, as $\frac{C}{C+a}$ then approaches 1 as a limit: which is thus a proof of the statement just made above. It is because of this property of Formula [3] that it may be considered as expressing an ultimate limit in a graduated-tax scheme; for, actually applied in practice, it would mean the practical confiscation of all large incomes, except for an amount which can never reach the value a. For a practical

taxation formula it is therefore necessary to assign a value to α in the general Formula [2] which is less than unity. In this case

$$L = C - T = C - \alpha \frac{C^2}{C + a} = \frac{C[C(1 - \alpha) + a]}{C + a}$$

$$= [a + C(1 - \alpha)] \frac{C}{C + a} \ldots\ldots\ldots\ldots\ldots [3]$$

which, as C becomes greater and greater, approaches the value $L = a + C(1 - \alpha)$ as a limit. That is to say, when α is assigned a value less than unity, a taxpayer of infinitely great income, and who as such would be left proportionately the smallest part of his income, would be left a certain definite fraction of his income in addition to the amount a. While under no circumstances should Formula [3] be used directly for tax purposes, it nevertheless suggests a rational relation of a single-man's tax to that of a married man.

Mr. Barth's recommendation is the adoption for a graded income, or other graded tax, of the general formula:

$$T = \alpha \frac{C^2}{C + a} \ldots\ldots\ldots\ldots\ldots\ldots\ldots [2]$$

to be applied directly to single men, and modified to

$$T = \alpha \frac{C^2}{C + a + b\left(1 + \dfrac{N}{m}\right)} \ldots\ldots\ldots\ldots [5]$$

for married men, in which N = number of children, and m a number which will depend on what consideration the number of children are deemed worthy of as compared with a wife. In the present law, which allows an exemption of \$200 for each child, five children have the same consideration as their mother. Values for a, b, and m might well be assigned to serve their purpose for any period, however long, during which the fundamental economic and social conditions of the country do not undergo any radical change, such that the value of α alone would be subject to change as often as the financial condition of the government might require more or less tax to be levied. However, in fixing relatively permanent values for a, b, and m, their significance when α is made 1 should have the most careful consideration.

As a matter of purely theoretical interest, Formula [5] may be written thus:

$$T = \alpha \frac{C^2}{C + a + b\left(n + \dfrac{N}{m}\right)}$$

in which n = number of wives, with only two alternative possible values in Christian countries; namely, 0 for single men and 1 for married men. With $n = 0$, N must also be 0, in which case the formula reverts to Formula [2].

Mr. Barth concludes his paper with a mathematical discussion of Formula [2] in combination with Pareto's law of incomes.

By a study through a term of years, of the income-tax returns of a number of European and other countries, the Italian economist Vilfredo Pareto discovered that the distribution of a nation's total income among its taxpayers is by no means a matter of chance only, but is subject to a very definite law which holds very closely except for the highest and the lowest individual incomes.

Mr. Barth reduces the mathematical expression for Pareto's law to

$$N = A/C^{1.5}$$

where A is a constant for any one country at any one time in its economic development, C any individual income, and N the number of individuals that enjoy incomes in excess of C.

From this and Formula [2] he finally derives the value for Y_t, the total tax of a nation when levied by Formula [2]:

$$Y_t = 3A(\alpha/\sqrt{a})\,[\tan^{-1}\sqrt{X/a} - \tan^{-1}\sqrt{M/a}]$$

in which M and X are the minimum and the maximum individual incomes, respectively.

FIRE PROTECTION IN MANUFACTURING PLANTS

By CHARLES E. RIGBY,[1] PROVIDENCE, R. I.

THE protection of factories against fire is nothing less than their conservation, which is vital to the maintenance of the national interests in the present emergency. Facilities for extinguishing fires, however, are only a part of the means needed to secure proper control of the fire hazard, and it is necessary to take also into consideration the construction, the character and arrangement of the processes, the protection, and last, the hazard from nearby property and safeguards against this.

Construction

In designing a building the purpose for which it is to be used must be kept in mind. What might be considered good construction for one occupancy, such as a heavy machine-shop building—one story high with gallery and with roof of plank on exposed steel—would be poor for another occupancy, such as a cotton mill. The ideal factory is one having a single story, because in structures several stories high each floor is exposed by the others. It is interesting to note that while around the Civil War period it was the practice to build factories about six stories high, with a tendency later toward one-story structures, today, on the whole, we seem to have struck an average between the two.

Mill Construction. The construction that first commands our attention is the slow-burning or mill-construction type, in which the walls are usually of brick and the floors and roof of heavy plank supported by wooden beams strong enough to permit their being spaced 8 to 10 ft. apart. On the plank floors there is a thickness of boards to serve as a wearing surface, and often an intermediate layer put down diagonally for the sake of stiffness. Columns preferably are of wood, although cast iron gives acceptable results. This method of factory construction results in assembling the wooden parts in large units, the strength of which is not easily destroyed by fire. To prevent a fire from traveling from one floor to another, care must be taken that all openings through the floors are protected. This is best accomplished by locating stairs, elevators and belts in brick towers with any openings protected by automatic fire doors. This is not always possible, particularly in buildings already erected, but for these cases the protection outlined should be approximated by enclosing stairways with partitions of two thicknesses of boards laid to break joints, by providing automatic self-closing hatches at

[1] Engineer, Blackstone Mutual Fire Insurance Co., Providence, R. I.
Abstract of paper presented at a meeting of the Connecticut Section, Meriden Branch, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, February 14, 1918.

the elevators, and by protecting the beltways with metal lath and plaster partitions or with substantial metal boxing easily removable for repairs.

Steel Construction. In steel construction the designer must keep in mind the likelihood of its quick failure, in the event of a fire, from bending or buckling. Fireproofing of steel in construction work is especially needed for columns in buildings several stories high, where the failure of a column in a lower story would bring down all above. Where there is to be a considerable amount of combustible stock it is also necessary to fireproof the beams, but for favorable occupancies, such as metal working, this is not always necessary except for important girders. For one-story buildings used for foundry and work of like nature, the use of exposed steel both for columns and girders is allowable.

Concrete Construction. The use of reinforced concrete makes possible a very safe factory, as each floor can be made a horizontal fire wall. It is unquestionably the type of construction best suited for use in congested sections. The cost, and sometimes the nature of business carried on, does not always warrant its adoption, although where loads are heavy and wide spans are desired, it is frequently not more expensive than other types of construction. Reinforced-concrete structures stood a severe test at the Edison Phonograph Works fire ot 1914. These contained much inflammable material, which furnished fuel for an intense fire. The buildings were badly damaged by spalling and splitting of the columns, collapse of a small portion, and expansion causing pilasters at the ends to shear off. The point of interest is that the buildings were repaired at 20 per cent of the original cost.

Poor Construction. Of the several types of construction that should be avoided, the first to be considered here is the so-called joisted type, which gives for floors and roofs one or two thicknesses of boards supported by joists 2 in. thick and a foot or two on centers. In many cases sheathing or plaster is attached to the under side of the joists, but in so doing concealed spaces are formed in which a fire is hard to fight. The open type cannot readily be protected by hose streams or sprinklers, as can the mill-construction floor. Contrast the strength of the two under a fire. If an inch is burned off from each side of the large beams used in mill construction, three-fourths of the strength is left, while if this same amount is burned from the joists, there is nothing left. In the joisted construction there is two or three times as much wooden surface exposed to the fire as under the mill-construction method.

Beware of *temporary* light frame buildings. Every insurance man knows that buildings so designated stay in service until they burn or are about ready to fall down. Not only are these structures poor risks in themselves but they frequently constitute a menace to neighboring property. If it is really thought that eventually a building will have to be removed to make way for some other unit, expanded metal and cement on iron framing will give satisfaction at moderate expense.

In old mills steep joisted roofs supported by trusses are sometimes found on buildings otherwise well constructed. Their use was dictated doubtless by the lack of satisfactory coverings for flat roofs. These steep roofs of light construction have proved to be fire traps, and it is worth while to replace them with flat mill construction, the gain in floor space alone being often sufficient recompense for the outlay.

Hollow tile is a poor material for building walls. When subjected to a fire the rapid heating of the exposed face of the tile causes it to expand and break away from the cooler portion.

The use of double floor beams has frequently been resorted to, but this should be avoided wherever possible. If they are located an inch or two apart it leaves a space where, experience shows, it is difficult to extinguish a fire. On the other hand, if the beams are bolted together the possibility of dry rot is increased.

Fire walls should not be omitted because a good protective equipment is to be provided. The protection may be out of service when a fire starts, on account of repairs or accident, and strong fire walls are needed to minimize the possibility of a total loss.

In recent years there has been more or less trouble because of dry rot or fungus growth, due to an inferior quality of wood. Timber so affected ignites more easily than sound wood and falls more quickly in event of fire on account of the rotting away of the ends. This disease is most likely to be found in damp places and investigations show that trouble from this source can be largely eliminated. Much good results from heating a building to a temperature of 115 deg. fahr. for a day or two as soon as it has been completed, and for wet occupancies, soaking the timber in a solution of corrosive sublimate is well worth the expense.

Occupancy

The arrangement of processes carried on in a manufacturing plant must meet two requirements: efficient production and the safety of the factory. This means, so far as possible, eliminating causes of fire and preventing small fires from becoming large ones.

Isolation of Severe Hazards. The first move is to locate the departments in which fire or explosion hazards are known to be serious in detached or well-cut-off buildings. This means boiler rooms at any plant, picking rooms of textile mills, the japanning room in a metal-working shop, the engine-testing room in an automobile factory, the dipping rooms in agricultural-implement plants, etc. In cities it is not always possible, on account of limited amount of land available, to provide separate structures to house these special hazards, and they are necessarily located in main buildings. In such cases it is well to fireproof the ceilings with metal lath and cement and separate the rooms from the main rooms by fire-retarding walls.

A point that should not be overlooked is that processes requiring materials or machines susceptible to water damage should not be located under rooms where fires are likely to occur.

Storage. A fire in a manufacturing building should involve only the stock that is in process of manufacture at the time. To accomplish this separate buildings are needed for storage of raw materials, finished goods, patterns, etc. The floor area of such structures should not be large and the buildings should be the equivalent of substantial mill construction. They should be only about eight feet from floor to floor in order that stock cannot be piled high, making it impossible for hose streams or sprinklers to do effective work.

Waterproof floors are desirable for some occupancies. For mill construction these may consist of two-ply felt laid between plank and wearing surface and mopped thoroughly with a waterproof compound, with special provisions at the edges and columns. Scuppers should be provided for carrying off the water. Where separate buildings for storage are not possible, the storage may be placed in the upper stories, as it is not then subjected to water loss if fires start in the manufacturing rooms, where fires are more to be expected than in storage areas. If it is necessary to locate storage in the lower part

... a building, the floors above can be waterproofe... described.

Oils. The danger which fuel oils bring can be ... great measure by careful handling. Storage should ... underground tanks and delivery by pumping. Gra... is highly objectionable, as is also air pressure for forc... oil from the storage tanks. Wherever possible, gasoline ... be handled by a hand pump. Fig. 1 shows a safe arrange-

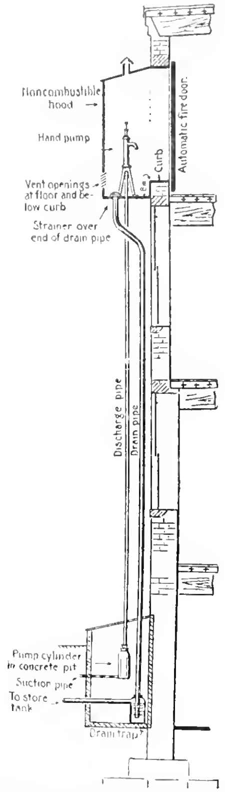

FIG. 1 ARRANGEMENT FOR FORCING GASOLINE TO AN UPPER STORY

ment where the oil is to be delivered to an upper story. Fuel oil is best delivered to the burners by a rotary pump, which can be driven by the same power that operates the blower furnishing the air for atomizing, insuring the automatic cessation of the flow of oil in case of failure of the air supply. The furnaces should be located in one-story buildings well cut off from the main plant.

Quenching-oil systems used in heat-treating plants have received considerable attention during recent years. A cooling system is desirable to keep the temperature of the oil below its flash point. Automatic covers and a quick-acting valve for drainage purposes are practical safeguards that are often neglected in oil tanks.

Kerosene has been used to a considerable extent in cutting oils. This introduces an unnecessary hazard, as careful investigations show that the work can be done as efficiently by emulsions or by selecting the right kind of oils. In a test made a few months ago a pan 30 in. by 48 in. was filled with straight cutting oil, and a bunch of cotton waste placed in the center and lighted. After 35 min. the fire had not spread from the waste to the oil. The same test was made with a mixture of 25 per cent kerosene and 75 per cent cutting oil, and in less than 1 min. the fire had spread over the pan.

Celluloid, although not an oil, needs as careful treatment. Burning celluloid is really a gas fire and needs to be treated as such. The amount in a factory should be limited to a day's supply, and this should be stored in a non-combustible cabinet such as that shown in Fig. 2, well vented to take care of the rapid generation of gases.

Housekeeping. A clean factory is essential. Waste materials must be removed daily and attention given to towers, corners, and out-of-the-way places. The advisability of keeping oily waste in metal cans is now generally recognized. A common source of trouble is from stock in contact with steam pipes. Charcoal is subject to spontaneous combustion and a piece of wood charred from long contact with a steam pipe will ignite. The best place to locate heating pipes is overhead. It is a bad practice to use sawdust on floors to absorb oil because of the danger of rapid oxidation.

PROTECTION

Automatic Sprinklers. The foremost method of factory protection is the automatic sprinkler, which is simply a $\frac{1}{2}$-in. opening with the valve held closed by various arrangements of links and levers and operated by the melting of a fusible link. A sprinkler was developed in 1875 that operated automatically in a practical way, although it took several minutes to work. Before that period perforated pipe protection, in which the pipes were perforated by small holes about eight inches apart, was in use. In case of fire it was necessary to open the valve controlling the water supply. This did not really meet the need because of delay in getting the water on the fire, and the wetting down of the entire room. This led to the development of the automatic sprinkler equipment, a sort of combination of the perforated pipe system and the fire-door-link principle.

An ideal arrangement of piping for a sprinkler system is shown in Fig. 3. This calls for a central feed and short branch lines. These two points are important because friction loss has to be reckoned with and it counts up fast in view of the large amount of water used. The sketch shows an equipment of 200 heads.

With the inlet from the yard main coming in at the center of the building, and assuming that all sprinklers are opened, 2700 gal. of water would be required and a pressure in the street pipe of 78 lb. If the riser is located in the corner, 3400 gal. of water and a street pressure of 119 lb. are necessary in order that the end head may have a fair working pressure.

At the beginning automatic-sprinkler protection was applied mostly to the danger points in textile mills, but gradually the mills became 100 per cent protected and the use of sprinklers was taken up by other industries.

Storehouse properties were the last to receive protection, as many of these structures are not heated, and this led to the development of the dry-pipe system, in which the danger of trouble by freezing is eliminated by permitting the pipes in the building to be filled with air. When a fire starts, the pressure in the piping is reduced as the air discharges through the sprinklers that have opened, and tripping of the air valve follows promptly, letting water into the system. This apparatus was viewed with suspicion for a time, but is giving a good account of itself and is now freely used.

The fact that a building is of non-combustible construction

is no excuse for the omission of sprinkler protection, and experience has shown the need of this wherever combustibles are present in the construction or contents. In very rare cases sprinklers may be safely omitted. Power houses and foundries, unless there is an objectionable amount of wooden flasks, fall in the class where it is sometimes logical to omit sprinkler protection if the construction is non-combustible.

One sprinkler under conditions as they are found will protect from 60 to 100 sq. ft., depending on the occupancy, spacings of beams, and water pressure available. For some very special hazards extra sprinklers are needed. Celluloid is one of these, requiring a spacing so close that shields have to be provided to prevent one sprinkler from playing on its neighbor and keeping it from operating. Generally sprinklers are so located that the splash plates come from 3 to 10 in. below the ceiling and under ordinary conditions are in an upright position. This enables the system to be completely drained in case of need and gives no chance for the head to become a small settling basin, as it would be if inverted. Sprinklers in dry-pipe systems should never be placed pendant. In rooms where conditions are favorable for corrosion, heads with a coating to prevent or retard this action can be secured.

Water Supplies. The value of sprinkler protection is largely governed by the strength of the water supply. This was curiously brought out by the Salem conflagration. A wooden factory building that passed through the fire had complete sprinkler protection supplied by city water and a 30,000-gal. tank. After water from the tank was exhausted the top story burned, but the city pressure was just sufficient to save the two lower stories without any assistance from the fire department. A specimen fire-protective layout is shown in Fig. 4. A connection with a good public water system gives the most satisfactory primary supply. Gravity delivery is best, while direct pumping systems must be looked on with suspicion. Sprinklers are most useful at the start of a fire and must have water instantly to do their work, a requirement which the direct pumping systems frequently do not meet. The initial pressure available is not of great interest, but we do need to know what the effective pressure will be if sprinklers requiring 1000 gal. of water or more a minute are opened by a flash fire.

When a satisfactory water supply cannot be obtained from a public water system, the customary resource is a gravity tank preferably erected on a steel trestle in the yard, but sometimes supported by one of the building towers.

The best of public water systems or gravity tanks are out of service at times to permit repairs or extensions, and while the gravity water supply may give sufficient pressure for sprinklers, it is not always strong enough for high-pressure hose streams; or, again, pressure in the public water mains may be reduced by use of hose streams, leaving nothing for the sprinklers. Therefore, a second water supply is required for the average factory. This frequently consists of the combination of the above two sources of gravity supply, but if conditions make it feasible, an Underwriter fire pump taking suction from some river, harbor or artificial reservoir built in the factory yard is still better. Steam, rotary, and centrifugal fire pumps have been designed especially for fire service. They are not built to obtain a high efficiency, although there are certain requirements in this respect, but the chief object is to secure a rugged pump that can be counted on for a long run. One or two pumps are needed, depending on the conditions and size of plant. In this connection it is well to remember that two 750-gal. pumps give a greater degree of safety than a 1500-gal. unit, as in case of accident to one of them the plant is not entirely without fire-pump service. The standard sizes of fire pumps are 500, 750, 1000, and 1500 gal. per min.

The type of pump to be used will depend largely on the power available. Rotary pumps are usually driven from water wheels, and if these are used there must be assurance that the power can be counted on the year round. If steam pumps are employed the power house must be cut off from the main plant by a fire wall, otherwise it might not be possible to run the boilers in case of fire; also the boiler feed should be from two independent sources, possibly one of them direct from the fire pump for emergency use only. The centrifugal fire pump

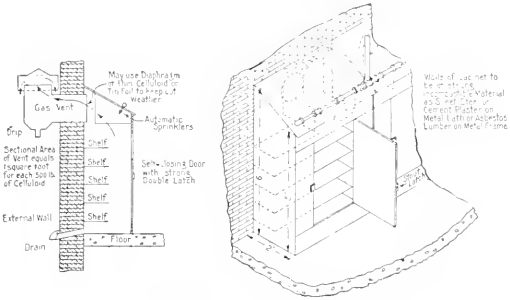

Fig. 2 Non-Combustible Cabinet for Storing Celluloid

is ordinarily driven by a motor. The current for power must be good and, unless there are some particularly favorable conditions, it needs to come from two independent sources to be the equivalent of the steam-pump equipment.

A fire pump must have a good foundation and good suction and it will then do reasonably well under very adverse conditions, but it is unsatisfactory if these two items are neglected. Long suction lines should be avoided and the intake defended by double removable screens. Centrifugal pumps should take water under a head if possible, but when this cannot be arranged priming facilities will have to be very carefully worked out and a foot valve of good design provided.

Yard Pipes, Hydrants and Standpipes. The pipes must have sufficient capacity to carry all the water available to any point in a factory yard without excessive friction loss, or at least as much water as will be needed to supply both sprinklers and hydrants for the property to be protected. Six-inch pipe is the smallest that should be used. For a factory of moderate size an 8-in. loop is usually sufficient, but for large properties pipe 12 in. or more in diameter is often required.

It is true that water can generally be used to the best advantage through the sprinklers, as these put it directly on the fire, while only a small portion of water from a hose stream might reach a fire. Nevertheless hydrants are needed as a reserve because a number of accidents might happen to the sprinkler system. Where yard room permits, hydrants should be located 40 or 50 ft. from the buildings, and should be in sufficient number so that hose lines over 150 or 200 ft. long will not be required. Faith should be placed in the sprinklers and the large hose stream not brought into use until it is certain that it is needed.

Hose for outside use in mill yards should be $2\frac{5}{8}$-in. cotton, rubber-lined. This should be kept in well-ventilated houses erected over the hydrants, which should also contain a supply of nozzles, spanners and similar equipment. The nozzles should have $1\frac{1}{8}$-in. smooth tips and swivel handles. Shut-off nozzles are not recommended for factory fire brigades.

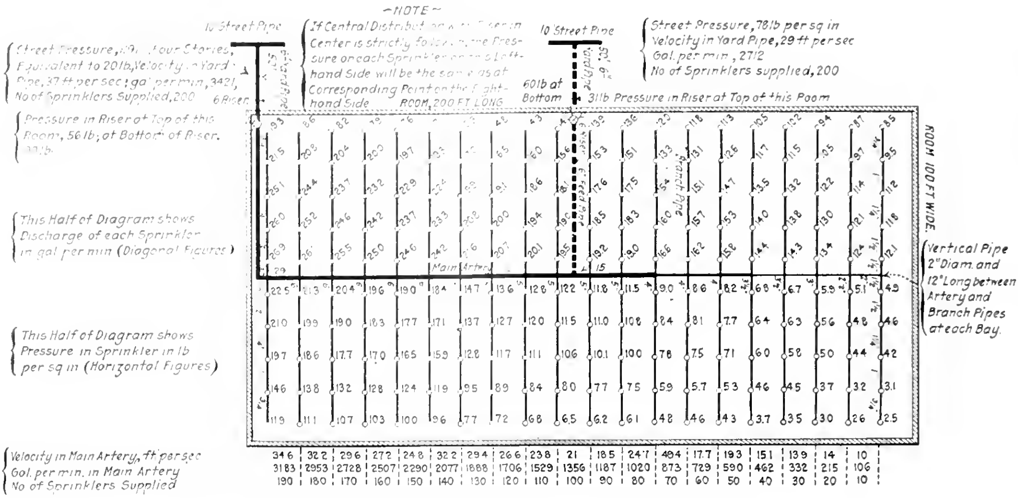

FIG. 3. IDEAL ARRANGEMENT OF PIPING FOR A SPRINKLER SYSTEM

Piping by schedule of November 1895, with new piping and central distribution. Figure shows water pressure that must be maintained at each sprinkler in room, if all the sprinklers are open, for the sprinkler in the farthest corner to receive an efficient supply.

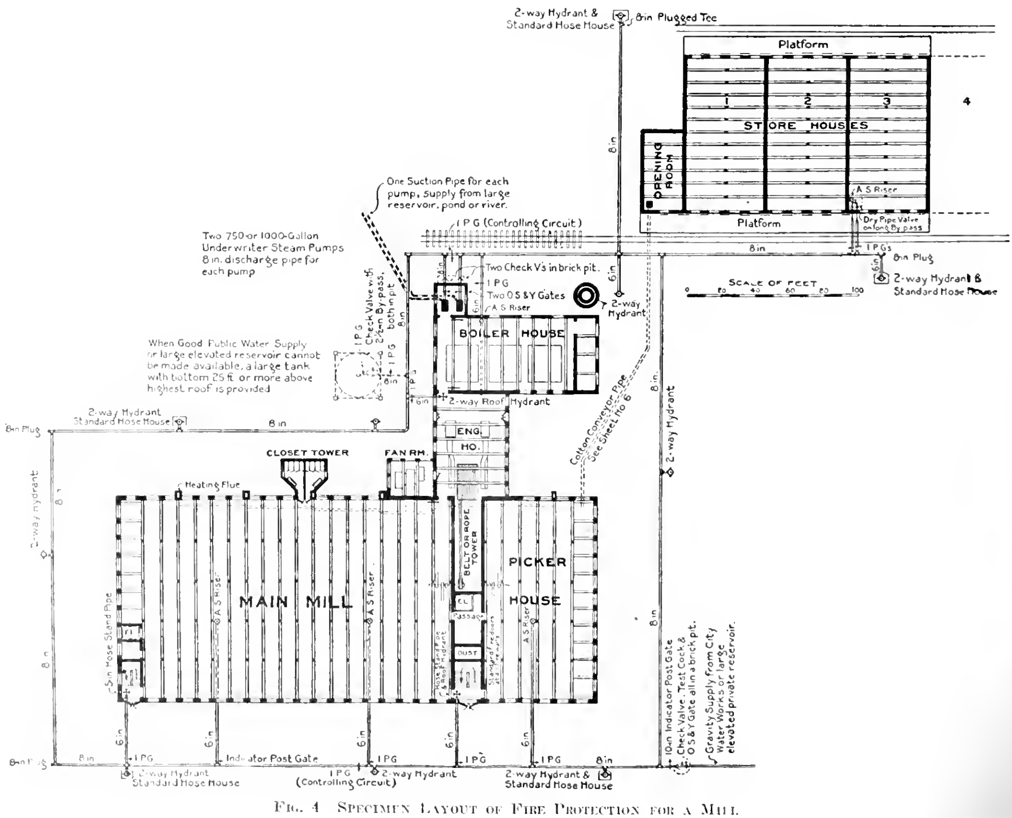

FIG. 4 SPECIMEN LAYOUT OF FIRE PROTECTION FOR A MILL

For buildings several stories high, hydrants should be supplemented by hose standpipes in the towers with $2\frac{5}{8}$-in. hose connections at each floor. Where there are other buildings in the yard, it is an advantage to extend the standpipes through the roof and provide roof hydrants. The towers are suggested as the best locations for the standpipes, as then a fire can be fought to the last minute without running a chance of having to leave without shutting off the water. Linen hose should be used for inside work, as the rubber-lined deteriorates rapidly when kept in warm rooms.

Indicator post valves in the yard should be placed on the branches supplying sprinklers. Inside valves should not be employed as their use is likely to prove disastrous in two ways: First, a fire may happen when the valve is closed and inaccessible because of fire or smoke; second, a fire may have gone beyond control by the sprinklers, or the sprinkler piping may have been broken, and unless the controlling valve can be reached the entire water supply may be wasted through the open pipe. A few section valves in the yard mains, to permit repairs to be made without shutting off the entire protective equipment, are worth while.

First Aids. It is claimed that the water pail has put out more fires than any other extinguishing apparatus, and it should not be omitted. Any man, woman or child knows what it is for and can use it. Small hose is also very useful and should, wherever possible, be attached to some pipe system other than that of the sprinklers. The ordinary liquid extinguisher gives good service. It is better than the fire pail for some conditions, such as fires in concealed spaces and in buildings where all there is to burn is the ceiling and this is too high above the floor to be reached by water pails. Generally speaking, however, the water pails are to be preferred. Dry-powder extinguishers have usually not proved as efficient for general duty. Comparatively recent investigations show that fires in dip tanks of moderate size can be handled more easily by use of sawdust than by sand because the sand sinks, but sawdust will float, forming a blanket which excludes the air. The efficiency of this method is increased by mixing sodium bicarbonate with the sawdust.

Watchman. For more than half the time the factory is in the hands of a watchman. This duty should not be given to an old employee in lieu of a pension, but to a strong man with ability to think quickly. It is desirable that records be made of the rounds on a suitable clock, and rounds should be made as often as once an hour, and should be arranged for at all times when the factory is not in operation.

Fire Brigade. An efficient, well-organized and drilled fire brigade is also essential for city properties, as well as isolated plants, for in any plant a certain number of men must be fully acquainted with the fire-protective equipment, and there is no better way to arrange for this than by means of a fire brigade. Again, there is the possibility that the public fire department may be busy fighting a large fire at some other point when a fire breaks out in a given plant. Frequent inspections by the chief and members of the public fire department should be encouraged, as by doing this they can become acquainted with the hazards and with what help the plant can be counted upon to give to control a fire. Unquestionably there are a large number of fires that should be handled by the men at the plant, who are entirely familiar with the processes and know fully what they have to contend with.

Care of Equipment. The greatest danger to a factory built and protected along the above lines is the possibility that the protective apparatus may be out of commission through neglect, accident or malicious design. The duties of the members of the fire brigade should therefore include an efficient oversight of the protective equipment. Every attention should be given to sprinkler valves, which should be listed on a report blank, and a copy of this taken when a tour of inspection is made. When protective equipment is necessarily shut off for repairs a member of the fire brigade should be stationed at the closed valve ready to open it if a fire breaks out, and other members should patrol the areas without automatic protection.

Exposures

Dangers that there may be from outside sources must be analyzed and safeguards provided. Outside hazards may consist of some fire trap only a few feet away, may be the possibility of a general fire in the section in which the factory is situated, may come from a forest, or may even appear by water if there happen to be some large oil tanks upstream. Of course, good building laws and their enforcement are fundamental aims. Perhaps this problem would not be so serious if we had the old French law making a property owner responsible for the damage done to his neighbor's property resulting from a fire originating in his own.

The best safeguard to minimize this danger is a solid brick fire wall on the exposed side. Good protection may be had by means of tin-clad wood fire shutters—never iron ones—by wire-glass windows in metal frames, by an equipment of open sprinklers over the windows to give a water curtain, or, for severe cases, by a combination of two of these methods. Combustible cornices should be removed or protected by open sprinklers, and there should be no wooden roof structures.

It is to be anticipated that the pressure in public water systems will fall off rapidly in a general conflagration because of waste through broken pipes in addition to the water used for fire fighting. It is very important, therefore, that the private fire-pump service be very strong where the exposures are severe, in order that there may be sufficient water available for hose streams, inside sprinklers and the water curtains. Much has been accomplished along this line by adjoining factories cross-connecting their fire-protective piping, making it possible to concentrate the pump service of all at any point. Private fire protection of this kind is a help to the community in checking the spread of a conflagration.

Conclusion

Does it pay to protect factory properties against fire loss or interruption to production because of fires? Two facts will be sufficient answer. The methods described are substantially the basis on which the New England factory mutual fire-insurance companies have been operating since their organization. Fifty years ago, before the day of automatic sprinklers and development of other fire-protective methods which we have been considering, the average cost of insurance in the Blackstone Mutual Fire Insurance Co.—one of the factory mutuals—was \$650 a year for \$100,000 insurance. Today, for the two companies in the Blackstone office, it averages less than \$65 for the same amount. Otherwise expressed, the fire waste in factories so protected and maintained has been reduced 90 per cent!

The methods of fire protection that have been applied have been as successful in safeguarding lives as property. Insurance amounting to over four billion dollars is now carried in the Factory Mutual Companies, which means that there are many hundred thousands of employees in the factories under their jurisdiction. The loss of life since automatic sprinklers were developed has averaged about one every other year!

SOME FACTORS IN FUEL ECONOMY IN BOILER PLANTS

By ROBERT H. KUSS,[1] CHICAGO, ILL.

THE total bituminous coal production in the United States during 1917 was close to 542,000,000 tons, and in the same year 90,000,000 tons of anthracite were marketed. The uses to which the bituminous coal was put have been estimated as given in Table 1. Forty per cent of the anthracite production was consumed by locomotives, and the remainder mostly by domestic users.

TABLE 1 BITUMINOUS COAL CONSUMPTION IN THE UNITED STATES, 1917

Kind of Plant	Tons	Per Cent
Stationary steam.	215,000,000	40
Railway locomotives	190,000,000	35
Households	135,000,000	25
	540,000,000	100

It is easy to see from Table 1 that 60 per cent of the total coal production in the United States during 1917 was applied to non-productive uses: namely, 35 per cent for steam locomotives plus 25 per cent for household use; or, to put it more strikingly, while the railways hauled all of the coal output it took 35 per cent of the coal production to conduct the entire business of hauling. Although impossible to form a coal budget for 1918, competent authorities seem to agree that the production must be increased by not less than one hundred million tons of bituminous coal.

Much needless transporting of coal has been practiced, and therefore the Fuel Administration's order restraining coal shipments within areas of natural consumption was good judgment. The hardships follow owing to the necessity of using a grade or quality of coal in equipment designed for a more distant product. This of course is particularly evident in the domestic field where West Virginia coal has been shipped in vast quantities to the larger population centers at a considerable distance.

With a fixed system for transporting coal and with added demands for its use, it is manifestly necessary to transport all coal possible during the summer months, thus compelling storage in vast quantities. The difficulties of storage, such as the likelihood of spontaneous combustion, are well understood and can be avoided.

While it is not possible to fix a definite figure or even range representing the ratio of heat absorption to that of possible heat evolution, or, stated otherwise, the efficiency, for the respective groups of manufacturing, locomotive and domestic use, it is nevertheless desirable to look into this phase of the matter. The average estimates which appear in Table 2 are accordingly submitted by the writer for what they are worth and have to do with the performances of the several groups applied to a year's period, all losses being charged.

Granting that all of these figures are merely speculative, they still show that the largest possibilities rest within the province of the duties naturally supervised by men such as ourselves. With respect to the large avoidable losses in burning domestic fuel, it must be borne in mind that even were the reclamation or saving of coal by more economical use larger than the estimates in Table 2 indicate, the difficulties attending a proper dissemination of knowledge to effect the possible economies are extreme.

Dealing with a single furnace the particular features needing consideration are:

a The character and physical condition of the coal

b The manner of introducing the coal into the furnace

c The shape, size and construction of the grate

d The shape and size of the chamber in which evolved gases burn

e The facilities for introducing air either through or above the fuel bed.

Any means which tend to cause the gases of combustion to be evolved or distilled uniformly are in the direction of complete combustion, and this is especially affected by the character of the coal and the method of introducing it. Manifestly, with a uniform gas distillation the cubical capacity of a furnace need not be as large as for variable distillation to obtain the same effect, for the determining factor in the complete distillation of fuel is sufficient air adequately mixed with the evolved gases and maintained at a high temperature long enough to insure the completion of the combustion process before encountering relatively cool surfaces.

TABLE 2 ESTIMATED PERCENTAGE EFFICIENCIES WHEN USING BITUMINOUS COAL

	Stationary Plants		Railway Locomotives	Domestic
	High-Pressure	Low-Pressure		
Poor practice.	50	40	60	30
Fair practice.	64	56	66	40
Good practice.	72-74	62	70	50
Available practice	76	68	72	55
Available increase.	12	14	9	15
Available savings, tons	25,800,000		17,100,000	20,250,000
Total tonnage saving on 1917 basis.				63,150,000

Air that does not enter into the actual combustion process is a source of loss whether the process is complete or not. Complete combustion does not argue economy, for the air admitted to bring it about may, and frequently does, exceed the amount required and be introduced in such places or in such ways as to offer itself as a vehicle for absorbing heat without assisting in its generation. Fundamentally, then, the items of importance are the rate and degree of uniformity of gas distillation. The usual failures in these particulars are due to the fact that the grate surfaces employed and air facilities provided are disproportionate to the steam demands, thus resulting in improper fuel beds and making it extremely difficult to cause the furnace to function as stated. Such conditions result in oversupplying air in certain sections, undersupplying it in others and in failing both to mix the air and gases and maintain them at a high temperature within the capacity of the furnace.

Referring to a particular design and condition of equipment, it happens that boilers perform at about the same efficiencies throughout their ranges of duty. In other words, clean, enclosed heating surface will absorb about the same

[1] Consulting M.E., Mem.Am.Soc.M.E.

Abstract of paper on the subject of coal conservation presented before the Detroit Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, May 3, 1918.

percentage of heat without regard to the quantity supplied to it within the range commonly encountered in practice, say, up to 250 per cent of builders' rating. This does not mean that all boilers are equally good or equally good heat absorbers; it has to do with the proposition that for a given design or shape of heating surface it is not essential to be concerned with the amount of heat delivered to envelop it, for the proportion absorbed will be practically the same in any case. On the other hand, the conditions surrounding boilers do play a big part in the resulting efficiencies and divide themselves mainly into cleanliness of both sides of the heating surface and the condition of the enclosing structure or setting of the boiler.

Boiler and furnace efficiency depend on the manner in which draft facilities are provided and utilized. In connection with draft there are the following points to bear in mind:

1 There must be provided a surplusage of draft intensity capable of being exerted at the fuel-bed end of the installation, so that momentarily greater steam demands may be met or temporary faults of fuel-bed construction overcome

2 Good judgment demands that the chimney or fan shall not have its purposes partially defeated by tortuous, ill-shaped breechings or faulty passages through the settings

3 Not only must the facilities for creating air movement through the fire be adequate, but the room delivering air to the system must have provision for the introduction of the volume of air needed for the combustion processes

4 Causes which tend to reduce draft intensity, as by soot deposits and air infiltration, not only bring about losses of their own accord but tend to destroy the available elasticity of furnace operation, which is more serious

5 Furnace draft should at all times be ample to overcome the resistance of the fuel bed

6 The rate of failure of furnace parts is inseparably tied up with the ability of the draft forces to carry away the heated gases as rapidly as evolved.

When several boilers are combined for service, there is usually a wide choice given in selecting the number to be run. Assume an ordinary plant containing eight 400-hp. boilers equipped with stokers adapted to the fuel being supplied. Suppose the draft facilities are ample and the load variation between 2500 and 2800 hp., momentarily going as high as 3000 hp. By ample draft is meant sufficient to burn without serious furnace injury enough coal (or more) on each grate to generate 760 hp. or 90 per cent overload. The ordinary way to run the plant would be to place six or seven boilers in service, keeping two or one down for general cleaning, and meet the load changes by altering damper positions, grate speeds, etc.

In Fig. 1 the line *AA* represents what may be termed the maximum combined efficiency over the range of operating rates. The mere fact that it is possible to attain these efficiencies at the different ratings does not secure their attainment. As a matter of fact, the lower the rate of operation the greater the opportunity for improper draft adjustments, poor fuel beds, uncleanliness and air leakages to go on unchecked and uncorrected. The effect is to obtain on the average a performance somewhat as represented in the efficiency curve *BB*. This has the characteristic of rising to a maximum height between 150 and 160 per cent of boiler rating. The conclusion is that it is best to run the boiler at around 150 and 160 per cent for normal loads.

Applying this judgment to the problem, take 2650 b.hp. as the mean point of service demanded and divide by 640, the latter figure being the product of 400 and 1.60. Thus four boilers will ordinarily carry the load if means are taken to operate the units at this rating. Now, how shall the momentary loads beyond be handled? By bringing up one unit at a time to its maximum capacity as the load increases up to the 3000 hp. of the original problem. In a like manner, when the load decreases, first one unit is reduced to, say, 110 per cent of rating, and if that reduction is not enough, a second unit is taken in hand, and so on. In other words, here is an attempt to push the operating forces to a place where they dare not neglect their duties lest they lose their grip on the steam pressure. When it is considered that fewer units are being

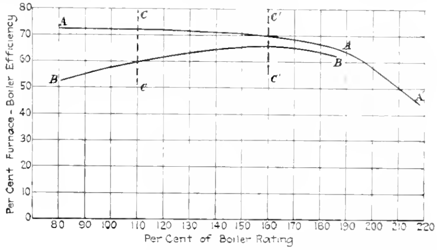

FIG 1 EFFECT OF VARIOUS RATINGS OF THE BOILER ON COMBINED EFFICIENCY

BB Usual operating efficiency.
CC—*C'C'* Proposed range of operating units.
C'C' Proposed rate of operating units for normal loads.
AA' Drop in efficiency due to insufficient furnace capacity.

watched and less fuel is handled, the net result is favorable to the operatives. The scheme advanced has many advantages for its application, as borne out by experience.

The above is a mild case and thus far only the immediate benefits in the way of economy have been stated. The corollary benefits no less important are: less blowing down; less soot accumulation and less effort and steam for its removal; less brick maintenance per ton of coal burned; less coal loss at the closing periods of the operating day and at other slow-down periods; greater time for inspection, overhauling, cleaning and repairs; and less percentage loss due to unavoidable losses such as radiation.

The ability to apply this system to its logical and best conclusion depends upon whether the available draft is adequate. If deficient, thus not permitting the attainment of a curve such as *AA*, then the opportunity for effecting the larger efficiencies is excluded, but the principle is still applicable. If the furnace capacity is inadequate, thereby causing its efficiency to fall rapidly at the higher rates, then the limits through which the scheme can be successfully applied are correspondingly reduced. If the plant is hand-fired (or even stoker-fired) and has less units than that mentioned in the problem, perhaps the exclusion of one whole unit may be impracticable; in that case each grate size should be reduced. Naturally it is extremely important to know just what the possible performance of each boiler unit may be throughout its range of working; also, what is expected of the plant as a whole in the way of steam demands.

Few instruments are needed for an ordinary plant, but those must be regularly used and the records reviewed and studied. Every boiler setting should have a draft gage or draft-gage system capable of instant or constant indication of boiler uptake and furnace drafts, and there should be accurate water-measuring and coal-weighing apparatus. Each chief engineer of a plant of, say, 600 b.hp. should possess a standard Orsat or gas-analyzing set and an indicating pyrometer.

REPORT OF THE COMMITTEE ON STANDARDIZATION OF FLANGES AND PIPE FITTINGS

To the Council of the American Society of Mechanical Engineers:

Your Committee on the Standardization of Flanges and Pipe Fittings has agreed on the following additions to existing standards comprised in its report known as The American Standard for Pipe Flanges, Fittings and Their Bolting, issued in 1914, and herewith presents them for your consideration and action:

Standardization of angle elbows and special angle fittings: From 1 deg. to 45 deg., use center-to-face dimensions of standard 45-deg. elbows, American Standard, and over 45 deg., use center-to-face dimensions given for 90 deg. American Standard elbows.

The following new standards have also been agreed upon:

1 A standard to be known as American Low-Pressure Standard for 50 lb. working pressure, tabulation of flange data at-

Note

1 For sizes 10 in. and smaller, use regular 125-lb. American Standard flange dimensions and templets.

2 For sizes 12 in. and larger, use 125-lb. American Standard flange diameters, bolt circles, and number of bolts, using bolt diameters as shown above, thereby maintaining interchangeability with 125-lb. American Standard flanges.

3 Screwed companion flanges should not be thinner than 125-lb. American Standard thickness.

tached. This standard was recommended after an agreement with the Committee of the Manufacturers' Association.

2 Three standards for hydraulic fittings, to be known as:

800-Lb. Hydraulic American Standard
1200-Lb. Hydraulic American Standard
3000-Lb. Hydraulic American Standard.

Tabulations and data for each of these standards with joint designs are submitted for your consideration. These are given in Tables 1 to 4 inclusive, and Figs. 1, 2 and 3.

Your Committee deems it inadvisable at this time to outline or recommend a standard for 600 lb. steam pressure with superheat, partly because there is at present no demand for fit-

	Length of bolts { Semi-steel	2 1/4	2 1/2	2 1/2	2 3/4	3	4	4 1/4	4 1/2	4 3/4	5 1/4	5 1/2	6	6 1/4	6 1/2	7	7 1/2	7 3/4	8
	{ Cast steel						3 1/2	3 3/4	4	4 1/4	4 1/2	4 3/4	5 1/4	5 1/2	5 3/4	6 1/4	6 3/4	7	7 1/4

These fittings are recommended for pump columns, oil-transmission lines, gas lines and other hydraulic service where shock is negligible for a maximum working pressure of 800 lb. and a maximum temperature of 100 deg. fahr. Where subject to shock they are recommended for a maximum working pressure of 500 lb.

The diameter of port is nominal size.

Reducing fittings carry same dimensions center to face as straight-size fittings corresponding to largest opening.

Flanges may be attached to the pipe by any of the following methods: Screw flanges; lap flanges; shrunk, peened or riveted flanges; flanges welded to pipe.

Flanges on fittings and valves, also all companion flanges except those for lap joint, should be furnished with 1/4-in. raised face, as shown in dimension table, Fig. 2, unless otherwise specified.

Bolt holes are 1/8 in. larger in diameter than bolts. Bolt holes straddle center lines. Unless otherwise specified, bolt holes in cast-steel fittings should be spot-faced.

Square-head bolts with hexagonal nuts are recommended. Hexagonal nuts on sizes 8 in. and smaller can be conveniently pulled up with open-end wrenches with minimum-design heads. Hexagonal nuts on sizes 9 in. and larger can be conveniently pulled up with box wrenches.

When flanges are screwed, shrunk, peened or riveted on the pipe, it is recommended that the end of the pipe and flange be refaced.

Gaskets extending from the inside of the pipe to the inside edge of the bolts are recommended. The ultimate compressive strength of the gasket must be sufficient **to** prevent its being crushed when bolts are pulled up.

Where long-radius elbows are desired, the use of pipe bends is recommended.

TABLE 3 1200-LB. HYDRAULIC AMERICAN STANDARD FLANGES AND FLANGED FITTINGS, 12 IN. AND SMALLER, FOR EXTRA STRONG WROUGHT PIPE. SEMI-STEEL AND CAST-STEEL (See Fig. 2)

1200 Lb. Cold Water Working Pressure — Hydrostatic (no shock)

These fittings are recommended for pump columns, oil-transmission lines, gas lines and other hydraulic service where shock is negligible for a maximum working pressure of 1200 lb. and a maximum temperature of 100 deg. fahr. Where subject to shock they are recommended for a maximum working pressure of 800 lb.

The diameter of port is approximately the same as the inside diameter of Extra Strong Pipe.

Reducing fittings carry the same dimensions center to face as straight-size fittings corresponding to largest opening.

Flanges may be attached to the pipe by any of the following methods: Screw flanges; lap flanges; shrunk, peened or riveted flanges; flanges welded to pipe.

Flanges on fittings and valves, also all companion flanges except those for lap joint, should be furnished with ¼-in. raised face, as shown in dimension table, Fig. 2, unless otherwise specified.

Bolt holes are ⅛ in. larger in diameter than bolts. Bolt holes straddle center lines. Unless otherwise specified, bolt holes in cast-steel fittings should be spot-faced.

Square-head bolts with hexagonal nuts are recommended. Hexagonal nuts on sizes 8 in. and smaller can be conveniently pulled up with open-end wrenches with minimum-design heads. Hexagonal nuts on sizes 9 in. and larger can be conveniently pulled up with box wrenches.

When flanges are screwed, shrunk, peened or riveted on the pipe, it is recommended that the end of the pipe and flange be refaced.

Gaskets extending from the inside of the pipe to the inside edge of the bolts are recommended. The ultimate compressive strength of the gasket must be sufficient to prevent its being crushed when the bolts are pulled up.

Where long-radius elbows are desired, the use of pipe bends is recommended.

tings for this pressure and because your Committee feels that it should be guided somewhat by experience in the field with the pressures and temperatures now in use, namely, 300 lb. pressure and 250 to 275 deg. superheat.

Your Committee, however, is ready to advise that for 400 lb. steam pressure and not exceeding 250 deg. superheat the 800-Lb. Hydraulic American Standard in steel is adequate.

These recommendations bring the work of your Committee up to date so far as any requests that they have before them for consideration are concerned.

TABLE 4 3000-LB. HYDRAULIC AMERICAN STANDARD FLANGES AND FLANGED FITTINGS, 12 IN. AND SMALLER, FOR DOUBLE EXTRA STRONG WROUGHT PIPE. CAST STEEL. (See Fig. 1)

3000 Lb. Cold Water Working Pressure — Hydrostatic (no shock)
2000 Lb. Cold Water Working Pressure — Shock
3000 Lb. Air or Gas Working Pressure — Temperature Not Exceeding 100 Deg. Fahr

See Fig. 1	Size	½	¾	1	1¼	1½	2	2½	3	3½	4	4½	5	6	7	8	9	10	12

H	Diameter of flange	4¼	4⅝	5¼	6	6¾	8	8½	9½	10¾	11½	13	14	15	16½	18½	20	21½	24
K	Thickness of flange	¾	⅞	1	1⅛	1¼	1⅜	1½	1⅝	1⅞	2	2⅛	2¼	2⅜	2½	2¾	2⅞	3	3⅜
L	Diameter of raised face	⅞	1 1/16	1 5/16	1 11/16	1 15/16	2⅜	2⅞	3½	4	4½	5	5 9/16	6⅝	7⅝	8⅝	9⅝	10¾	12¾
M	Height of raised face	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼	¼
N	Minimum metal thickness	7/16	½	½	9/16	9/16	⅝	¾	⅞	1	1 3/16	1⅜	1½	1⅝	1¾	1⅞	2	2⅛	2⅜
	Diameter of bolt circle	3	3¼	4	4⅝	4⅞	6	6½	7½	8½	9¼	10½	11½	12½	13¾	15½	17	18½	21
	Number of bolts	4	4	4	4	4	4	8	8	8	8	8	8	12	12	12	16	16	20
	Diameter of bolts	½	⅝	⅝	¾	⅞	⅞	⅞	1	1	1⅛	1¼	1¼	1¼	1⅜	1½	1½	1½	1½
	Length of bolts	2¼	3	3¼	3¼	4	4¼	4½	5	5½	6	6¼	6½	6¾	7¼	7¾	8	8¼	8½

These fittings are recommended for hydraulic service where shock is negligible for a maximum working pressure of 3000 lb. and a maximum temperature of 100 deg. fahr. Where subject to shock they are recommended for a maximum working pressure of 2000 lb.

The diameter of port is approximately the same as the inside diameter of Double Extra Strong Pipe.

Reducing fittings carry same dimensions center to face as straight-size fittings corresponding to largest opening.

Flanges may be attached to the pipe by either of the following methods: Screw flanges; flanges welded to pipe.

Flanges on fittings and valves should be furnished with ¼-in. raised face, as shown in dimension table, Fig. 3, unless otherwise specified.

Screw flanges are furnished with plain face and are threaded with American Briggs Standard lock-nut threads. The pipe should be threaded with American Briggs Standard lock-nut threads, and the end of the pipe should be faced off square. The pipe should be screwed through the flange until the end projects about ½ in. beyond the face of the flange and bears against the gasket.

When flanges are welded on the pipe the end of the pipe should project through the flange and should be faced off square to form the raised face.

Bolt holes are ⅛ in. larger in diameter than bolts. Bolt holes straddle center lines. Unless otherwise specified, bolt holes should be spot-faced.

Square-head bolts with hexagonal nuts are recommended. Hexagonal nuts on sizes 5 in. and smaller can be conveniently pulled up with open-end wrenches with minimum-design heads. Hexagonal nuts on sizes 6 in. and larger can be conveniently pulled up with box wrenches.

Gaskets extending from the inside of the pipe to the inside edge of the bolts are recommended. The ultimate compressive strength of the gasket must be sufficient to prevent its being crushed when the bolts are pulled up. Soft metallic gaskets at least 1/16 in. thick are recommended.

Where long radius elbows are desired, the use of pipe bends is recommended.

It is the desire of the Manufacturers' Association that the standards herein outlined be made effective at the earliest possible date. Your Committee, therefore, respectfully invites your early action.

Respectfully submitted,

Committee on Standardization of Flanges and Pipe Fittings

Received by the Council, April 23, 1918, and ordered printed. For presentation at the Annual Meeting, December 1918, of The American Society of Mechanical Engineers, 29 West 39th Street, New York. This paper was prepared under the direction of J. P. Sparrow, deceased, the late Chairman of the Committee. All papers are subject to revision.

THE WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretations, in the form of replies, are then prepared by the Committee and passed upon at a regular meeting of the Committee. These interpretations are later submitted to the Council of the Society for approval, after which they are issued to the inquirer and simultaneously published in The Journal, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 194-199, inclusive, as formulated at the meeting of July 31-August 1, 1918, and approved by the Council. In this report, as previously, the names of inquirers have been omitted.

Case No. 194

Inquiry: Is the reservoir or tank of a steam storage locomotive built with running gear exactly similar to an ordinary steam locomotive, but having instead of a boiler, a storage tank filled about 80 per cent with hot water at 180 lb. pressure, to be considered as a steam boiler and thus subject to the rules of the Boiler Code, or as an unfired pressure vessel, and thus exempt therefrom? The tank has no fire box nor staying nor other features which are responsible for corrosion and scale, and it is usually designed for a factor of safety of 4, being fitted with a safety valve of ample proportions.

Reply: It is the opinion of the Committee that the unfired reservoir of such a locomotive is not subject to the rules of the Code.

Case No. 195

Inquiry: Is it necessary, under the requirements of Par. 185, to plane down to ½ in. on the top of the shell the portions of the plates forming the laps of girth joints of an h.r.t. boiler with setting of the third-pass type?

Reply: Par. 185 of the Boiler Code requires that the portions of plates, exceeding ⅝ in. in thickness, which form the laps of girth joints in h.r.t. boilers, shall be planed or milled down to ½ in. in thickness wherever exposed to the products of combustion.

Case No. 196
(Annulled)

Case No. 197

Inquiry: An interpretation is requested relative to the application of Par. 9 of the Boiler Code to handhole covers and plates. Are they considered as a part of the boiler proper so as to come under the requirement of Par. 9, or may they be considered as fittings and thus permissible of cast-iron construction under Par. 12?

Reply: The Boiler Code does not prohibit the use of cast-iron for handhole plates except for certain temperature limits as specified in the Code. See Par. 12.

Case No. 198

Inquiry: Is the plain unstayed circular furnace, 16⅜ in. outside diameter by 16 in. high, of a vertical tubular boiler, subject to the requirements of Par. 239 of the Boiler Code, with proposed revisions, which will allow it a reasonable working pressure, or to Par. 241*a*, which will allow it a pressure of only 70 lb.?

Reply: It is the opinion of the Boiler Code Committee that the formulæ given in Par. 239 should be employed for computing the allowable pressure of this furnace.

Case No. 199

Inquiry: Is the requirement of Par. 265 covering a washout hole in the front head applicable to the railroad locomotive type of boiler which is so obstructed by the dry pipe, spark arrester screen, and other smoke box equipment as to render it absolutely inaccessible without dismantling the locomotive?

Reply: It is the opinion of the Boiler Code Committee that the requirement of Par. 265 applies only to locomotive type boilers in traction, portable or stationary service and not to railroad locomotive boilers.

Case No. 190 (Reopened)

Inquiry: Is it the intention of the interpretation in Case No. 190 to include vertical firetube boilers as well as boilers of the Manning type which differ from the vertical tubular type only in the use of the Manning OG ring?

Reply: The original reply in Case No. 190 was so worded as to cover the vertical joint of any form of internal furnace where the joint is fully supported by staybolting.

Case No. 191 (Reopened)

Inquiry: Does the interpretation formulated in Case No. 191 permit the steel manufacturer to cut butt straps as called for by the customer, or if the customer expresses no preference, then to cut the butt straps in whatever direction his judgment and convenience may dictate, and make the tests from the plate as rolled, as provided in the specifications for boiler plate steel?

Reply: The steel manufacturer is privileged to shear butt straps from the plate as rolled in whichever direction the orders of the customer or the manufacturer's convenience may dictate, the tests to be made from the plate as rolled, as provided in the specifications for boiler plate steel.

The Canadian Engineering Standards Committee has been organized with official representation from the government departments, the Canadian Manufacturers' Association and several technical organizations. Its objects are to secure interchangeability of parts, to reduce cost of manufacture by the elimination of multiplicity of designs, and to effect improvements in workmanship and design.

The following officers were elected: Chairman, Sir John Kennedy; vice chairmen, H. H. Vaughan, Mem.Am.Soc.M.E., and Capt. R. J. Durley; honorary secretary-treasurer, Dr. John B. Porter; secretary, Frank S. Keith. The headquarters will be at 176 Mansfield Street, Montreal.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Suggestions for the Conservation of Tin

To the Secretary:

Concerning the matter of Tin Conservation which has recently been referred to our Sub-Committee on Bearing Metals, we most heartily approve of the work already done by the various agencies in the field of tin conservation, now in general coöperation with the Government. It is evident that in order to accomplish most effective results in this field a very general whole-hearted coöperation should exist between all users and consumers of tin. Fortunately this condition is evident throughout the entire country.

We fully realize that it is impossible to lay down hard and fast recommendations to govern all cases, since so many exceptions and special requirements must always exist. We feel, therefore, that our suggestions at this time should be of a purely technical nature such as will prove of permanent and lasting value.

In general, we would call the designing engineer's attention to the fact that the tin-base babbitts are far more generally used than necessary, and that where service conditions permit the use of a lead-base babbitt, the most satisfactory results are obtained by such use.

In general, tin-base babbitts should be restricted to bearings subjected to extreme service conditions, to those under excessive loads, repeated impacts and severe shocks. However, even under these conditions it is possible to reduce the tin consumption by an improved construction in which the layer of babbitt is made thinner. This is accomplished by sweating a thin layer of babbitt into a steel backing or shell made of tubing, and thus producing a very superior construction, while at the same time accomplishing the purpose of conserving tin.

It seems advisable that the use of tin-base babbitts be restricted to those having the following two limits of composition: namely, from 0 to 21 and from 76 to 88 per cent of tin. Those falling within the lower limits should be used far more generally than those of the higher limits.

At this time, also, it seems opportune to call attention to an old bronze formula: namely, 88 copper, 10 tin and 2 zinc, commonly known as gun metal or ordnance bronze. This should be entirely superseded by a composition having substantially 90 copper, 6.5 tin, 1.5 lead and 2 zinc, which is a superior composition in every respect. In general, it is stronger and more reliable; is more economical in foundry production; is easier and more satisfactorily machined; for hydraulic work is less liable to leaks; in steam service it is from 5 to 40 per cent stronger than the old composition; while at the same time this substitute formula offers a saving of $3\frac{1}{2}$ per cent of tin, which is always wasted in the old formula incident to the production of an inferior alloy.

A copper-tin bronze having more than a minute trace of phosphorus should be used for bearing purposes only when the corresponding bearing member is made of hardened or high-carbon heat-treated steel. A copper-tin bronze containing no lead and whose tin is 9 per cent, or more than that of its copper content, should never be used with the softer low-carbon machinery steels. A copper-tin bearing bronze in which the tin is as high as 9 per cent of its copper content, or higher, and at the same time which contains zinc, should also contain lead in amount not less than its zinc content.

We would also call attention to the fact that where exacting chemical conditions and flowing requirements do not exist, solders having a low percentage of tin can be used far more generally, and in many cases even produce a superior product. The composition of 60 lead and 40 tin is the strongest and most plastic alloy of these constituents, having a melting point of 39 deg. fahr. higher than a 50-50 solder. For many purposes it has been found that the lead can be increased even beyond this point, and thereby still effect a very satisfactory economy.

Respectfully submitted,

C. H. Bierbaum, *Chairman*
J. A. Capp
H. Diederichs
Sub-Committee on Bearing Metals.

September 12, 1918.

Fuel Administration in Missouri

Prof. H. Wade Hibbard, Mem.Am.Soc.M.E., of the University of Missouri, who has recently been appointed District Engineer of the United States Fuel Administration for the North Central District of Missouri, has sent interesting information regarding his work in the district. He expresses the hope, which the editor earnestly seconds, that others who are actively engaged in the work of winning the war should contribute to The Journal accounts of their experiences.

Professor Hibbard refers to the great usefulness of Bulletin No. 1 of the Advisory Committee of the Massachusetts Fuel Administration, a portion of which was reproduced in The Journal for August, page 692. He states that his district is 140 miles long north and south, and 133 miles long east and west, with 83 public-service utilities and several times that number of other plants and factories. He is engaged in organizing the work and stimulating local patriotic sentiment along the lines of fuel and power conservation.

Every man wants to be doing something in the war and owners and operators too old or otherwise unable to "make" the Army, are still able to send substitutes to the Army. The power-plant operator or factory owner who can save one coal-miner's annual output of coal is in effect sending a "substitute" to carry a rifle *over there*. In our Civil War a man could *hire* a substitute to go in his place; but the *miner-substitute* is a very different and much finer idea.

It is expected to have fuel and power committees in each plant and an advisory committee to unify and help the work in each town, and also a county advisory committee in each county. The largest city in the county is made a conservation center.

Mr. J. A. Whitlow, Mem.Am.Soc.M.E., Administrative Engineer, is in charge of this work in Missouri. His connection for years with the public-service work forms an especially favorable circumstance for the quick and effective organization of the state, he being already personally acquainted with all of the public utilities and their operators and with most of the engineers.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, Including Abstracts of Articles in Current Technical Periodicals

Waste Reclamation

A meeting was recently held by Hugh Frayne, member of the War Industries Board and chairman of its War Prison Labor and Reclamation Section, with various section chiefs in the War Industries Board and representatives of other agencies concerning the important matter of the reclamation of waste materials. A general plan was outlined for uniformity of method and coöperation among the various agencies in reclaiming materials much needed in the Government's war program.

As an illustration of the value of reclamation work that can be done, Mr. Frayne pointed out that during June and July 17,000 soldiers were completely outfitted with shoes, hats and clothing from material which other soldiers had discarded. All of this material was disinfected, renovated, and repaired or remade, instead of being allowed to go to the junk pile. This work was done through the reclamation division of the Quartermaster's Department, of which Col. J. S. Fair is in charge. (*Official Bulletin*, August 13, 1918, p. 15)

Plant to Make "Carbocoal"

It is stated by the Fuel Administration that the U. S. Government has become interested in the establishment of a plant at Clinchfield, Va., for the manufacture of "Carbocoal," a smokeless briquetted fuel produced from bituminous coal. This has developed as the result of tests on the briquets made by the Navy Department and two railroad companies. The plant, which is now in the preliminary stages of construction, is expected to be in operation early in 1919 and will have a capacity of treating several hundred thousand tons of bituminous coal annually.

A new process of low-temperature distillation is used by which coal is so treated as to recover greater quantities of the valuable by-products, such as toluol, sulphate of ammonia, and valuable oils. The briquets are made from the residue. Tests of carbocoal disclose that it contains less than 4 per cent of volatile matter, rendering it practically smokeless, and that it is satisfactory where there is limited grate area and restricted boiler capacity. (*Official Bulletin*, August 27, 1918, p. 8)

New Department of the Engineer Depot

Few realize the immense volume of work accomplished by the General Engineer Depot at Washington in supplying the engineering equipment required by the Army in this country and abroad. The fact that its various departments have often accomplished the seemingly impossible is indicated by the slogan of the Depot, "It can't be done, but here it is." Specifications have been issued and orders placed for supplies to the extent of $5,700,000 by a single department in a single day. The personnel of the Depot comprises a staff of 3600 situated in different parts of the country, with 150 engineers of the first class. Thirteen of the Washington staff are members of this Society.

Announcement has been made of a new division of the Depot on Investigation, Research and Development, of which Major O. B. Zimmerman, Mem.Am.Soc.M.E., is in charge, covering the following subjects: Searchlights; surveying; map production; sound ranging; engineer equipment; testing mechanical and optical devices; physical and chemical research and tests; coöperation and coördination; information sources and patents; heavy-equipment developments.

Among the functions of this division are:

1 To review, follow up and initiate improvements in the military equipment and supplies of the Mobile Army, in coöperation with purchasing officers of corresponding equipment and with cognizance of manufacturing facilities and available materials.

2 To conduct or follow chemical and physical tests of material and equipment; and to conduct efficiency tests.

3 To assist in the creation of suitable specifications and advise on technical questions.

4 To assist officers of the Depot to develop their ideas into patentable form in order to protect the Government against the payment of royalties for ideas originating in the Depot.

Prevention of Accidents in Government Nitro Plant

The United States Employees' Compensation Commission issues the following:

A remarkably low accident record has been effected during the construction of the United States explosive plant C, at Nitro, W. Va., which was begun the early part of January 1918. This is attributed directly to forethought and careful planning in the elimination of accident hazards through concerted effort in modern methods of safety engineering.

This plant covers approximately 1600 acres of land, upon which are constructed hundreds of buildings to be used in the manufacture of smokeless powder. In addition to the plant acreage there are about 900 acres of land, upon which are being constructed thousands of homes in which the operators will live.

No records in the United States accident statistical record books, past or present, have been more wonderful than those now shown at this Government powder plant, where, to date, there has been but two-tenths of one per cent of the number of working hours lost by injuries resulting from accidents causing absence of employees.

But six fatalities have occurred at this plant during the past eight months of its construction period, where upward of 19,000 employees have been working overtime and Sundays to complete this gigantic project. Only 8 accidents per 10,000 employees per day have occurred, entailing loss of one day or more.

The supervision of this accident-prevention work has been done by a well-organized safety department which, representing the United States Employees' Compensation Commission, at Washington, D. C., has been under the direction of C. B. Hayward, safety engineer in charge. Its activities, coupled with the assistance and coöperation of the officials down to the workmen, have made it possible to create this new mark in accident-prevention work. (*Official Bulletin*, September 4, 1918, p. 7)

British Scientific Products Exhibition

This exhibition was formally opened at Kings Co[illegible], London, on August 11, and remained open every week[illegible] September 7. It was organized under the auspices [illegible] British Science Guild with the assistance and coöperation [illegible] large number of scientific technical societies and institu[illegible]s, as well as various official and municipal authorities and [illegible] manufacturers.

The exhibition was not intended to be a direct meeting ground between purchaser and manufacturer but rather to enlighten the public as to the scientific and industrial strength and adaptability of the country, as well as to stimulate confidence in the national capacity to meet not only the needs of the present but also the demands of the future. It was intended also to make clear the value of scientific research to the arts and industries and to show how much, in this regard, had been successfully achieved since the beginning of the war, which, in many directions, revealed an appalling dependence of Great Britain on foreign products and instruments.

Many things done in the last four years could not be exhibited for reasons of military secrecy, but it proved possible to make a very good showing even in such lines, as, for example, in aeronautical progress, where military considerations are predominant. One of the difficulties encountered was to find a sufficient number of men that could be spared from actual war work and still be competent to answer questions of visitors. This difficulty was solved by making arrangements by which college students were used as demonstrators.

During the course of the exhibition lectures and demonstrations were given. Sir William Tilden spoke on Recent Progress in Industrial Chemistry and representatives of the Munitions Invention Department demonstrated the oxidation of ammonia.

Engineering, from which the above data were taken (vol. 106, no. 2746, August 16, 1918, pp. 177-178), gives an extensive serial account of the exhibition, of which the article referred to above in the issue of August 16 is the first installment.

Explaining the Fuel Regulations

The fundamentals of the national program of fuel conservation in power plants are (*a*) personal inspection of every power plant; (*b*) rating and classification of every plant, in classes, depending on the thoroughness with which the owner conforms to the recommendations of the Fuel Administration; (*c*) at the discretion of the Administration the supply of coal to any needlessly wasteful plant may be stopped.

For the carrying out of the second stage of this program, the Fuel Administration, through its advisory engineer, Mr. David Moffat Myers, Mem.Am.Soc.M.E., has prepared standard recommendations regarding measuring and recording fuel, heating feedwater, regulating air supply, cleaning heating surfaces, maintaining and insulating settings, supervision of boiler and engine plants and of plants in buildings and shops.

As explained by Mr. Myers, this part of the work represents only one side of the fuel-conservation work, but it is the side which most concerns engineers and upon which the Fuel Administration looks to the engineer for coöperation. Mr. Myers has consented to appear before the members of the Society at the Indianapolis joint section meeting on October 25 and 26 and tell those present just what the Fuel Administration expects of the engineer. At this same meeting, too, Dr. P. B. Noyes, Department of Publicity and Education, will give an explanation of the regulations of the Fuel Administration. Full particulars appear elsewhere in this issue.

Standard Symbols in Mechanics

A great deal of work has been done by the Society for the Promotion of Engineering Education in attempting to secure uniformity of practice in the use of uniform symbols and abbreviations used in technical literature. Prof. John T. Faig, Mem.Am.Soc.M.E., has taken an active interest in this useful work and has furnished for publication the following symbols for formulae in mechanics which were approved by the S. P. E. E. on June 28, 1918.

Concept	Symbol.
Acceleration, angular	α (Alpha)
Acceleration due to gravity	g
Acceleration, linear	a
Area	A
Breadth	b
Center of rotation	O
Coefficient of friction	f
Coefficients and constants	C, K
Deflection of beam	y
Depth	d
Diameter	D
Distance passed over	s
Distance of extreme fiber from neutral axis	c
Eccentricity of application of load	e
Efficiency (hydraulic, mechanical, volumetric)	e_h, e_m, e_v
Force	F
Force, moment of	M
Friction, coefficient of	f
Head	H
Height	h
Horsepower	$hp.$
Hydraulic radius	R_h
Inertia, polar moment of	J
Inertia, rectangular moment of	I
Length	L
Load, eccentricity of application of	e
Mass	m
Modulus of section	Z
Modulus of elasticity, Young's	E
Moment of force	M
Moment of inertia, polar	J
Moment of inertia, rectangular	I
Quantity of liquid flowing	Q
Radius	r
Radius of gyration	k
Reactions	R
Revolutions per unit of time	N
Stress, unit	S
Time	t
Torque	T
Velocity, angular	ω (Omega)
Velocity, linear	v
Volume	V
Weight	W
Young's modulus of elasticity	E

U. S. Munition Output

Official report of newspaper interview with the Acting Secretary of War (condensed):

I will give you the facts about the big gun plant we are constructing at Neville Island. We signed a contract with the United States Steel Corporation to build and operate without profit this plant for guns of the larger calibers. This is the biggest plant of this kind ever conceived. The site is just below Pittsburgh and covers about 1000 acres. The housing will be on the hills south of the Island. The amount of money involved is $150,000,000. This plant will handle a tremendous amount of material.

Q. Will this plant be available for other uses after the war?

A. The plant will always be able to make steel and heavy forgings. A great deal of the machinery is special for large-gun manufacture.

Q. Will the plant be available for naval guns after the war?

A. The Government will retain it after the war.

Q. How large will the guns be from the Neville plant?

A. A 14-inch will be the minimum.

Q. Can you tell about the maximum?

A. No.

Q. What plants besides the Bethlehem are now building big ordnance?

A. About 12 finishing and 12 forging plants. This number includes Bethlehem.

Q. Did you say we had shipped two hundred and fifty 155-mm. guns?

A. Yes, to France.

In reply to further questions Mr. Crowell stated: We are producing between 25,000 and 30,000 machine guns per month. Of the Browning heavy we are producing 6000 to 7000, and the Browning light automatic rifle from 8000 to 9000 per month.

Tractors: We are getting production, but it is not nearly what it should be. We are making about 1200 per month.

Rifles: The production has been steady, about 200,000 per month.

Pistols and Revolvers: We produce between 50,000 and 60,000 per month. We are expediting this.—(*Official Bulletin*, Sept. 4, 1918, pp. 1 and 6).

Meetings of Other Societies

Smoke Prevention Association

About fifty delegates, including municipal smoke inspectors, fuel supervisors and inspectors, and others, were present at the thirteenth annual convention of the Smoke Prevention Association held at Newark, N. J., August 20-22.

Several addresses were made on topics of general engineering interest. Newell W. Roberts, Vice President, International Coal Products Corporation, explained that "carbocoal" (mentioned elsewhere in this number), consists primarily of fixed carbon and contains only 1½ to 4 per cent of volatile matter. In combustion the fuel is smokeless, igniting with comparative ease and burning freely and completely under all ordinary draft conditions. The fuel, shaped by a briquet machine to insure a maximum density, is uniform in size and quality, dustless and clean. In structure it is hard and tough, permitting ordinary handling and transportation for long distances without disintegration. In color it has a resemblance to coke, being grayish black and with a density closely similar to that of anthracite coal.

Frank W. Casler, General Superintendent of Production, Public Service Corporation of New Jersey, in a paper termed Experience in Burning a Million Tons of Coal a Year, and How We Supervise It, said that the method of procuring a coal supply today has changed very materially from what it was in pre-war times. Then the contracts called for coal to be delivered to hand-fired plants where the smoke abatement was an important factor of not more than 17 or 18 per cent volatile matter; but now the average volatile matter ranges from 23 to 25 per cent. In purchasing coal the Corporation specifies that the average ash for any one month shall not exceed a certain percentage; sufficient leeway is allowed for reasonable variation, and should it exceed this amount penalties are applied, but no premiums are paid if the average falls below what is specified in the contract, the object being to maintain a fuel supply of uniform quality.

H. D. Savage, Vice President, Locomotive Pulverized Fuel Co., referred to results attained with pulverized fuel on the Atchison, Topeka & Santa Fe R. R., the Hudson & Delaware Co. and the Central Railway of Brazil. As regards its use in stationary plants, he pointed out the possibilities for the commercial employment of such fuels as Rhode Island graphite anthracite, lignite coal of the South and Northwest, and the anthracite culm and slush, in Pennsylvania. A series of tests made in June, 1918, with an Edge Moor boiler, using Illinois and Indiana screenings, showed an efficiency of boiler and furnace of 83.33 per cent, during a 12-hour period. The increase in efficiency over using the same grade and quality of fuel on grates or in retorts was 15 per cent, with a value of fuel saving during the period of run, at $5 per ton, of $0.80. The one difficulty manifest in the use of pulverized coal is that it cannot be stored for long periods without danger of spontaneous combustion.

W. S. Bartholomew, Locomotive Stoker Co., presented a résumé of Mechanical Stoking of Locomotives as Related to Smoke Prevention Problems. Up to the present time 4500 mechanical stokers are in service on the railroads distributed over locomotives with from 50,000 lb. to 100,000 lb. tractive effort. The United States Railroad Administration has ordered mechanical stokers for application to all locomotives now in course of construction with a tractive effort of 50,000 lb. or over, and mechanical coal passers for smaller locomotives to be built.

Other papers were, Boiler Room Efficiency, by A. H. Blackburn; Smokeless Combustion with Chain Grate Stokers, by Thomas A. Marsh, and Bituminous Coal for Heating Boilers, by William A. Pittsford. (From the report of the Convention given in *Power*, September 10, 1918.)

Association of Iron and Steel Electrical Engineers

The twelfth annual convention of the Association of Iron and Steel Electrical Engineers was a well-attended meeting, held at Baltimore, Md., September 11-14. Besides several technical papers, two important committee reports were discussed on Rules for Safe Operation of Electric Cranes; and Methods of Education for Electrical Employees.

The first report outlines explicitly the duty and authority of each employee in matters of safety and calls attention to the reasonable requirement of the law that employees should be instructed in the hazards of their work, and to the fact that this requirement cannot be complied with more effectively than by supplying each employee with a printed copy of such instructions, which without abrogating the obligation of those in authority to give verbal instructions, will preclude the possibility of denying that full instructions have been given.

The second report is based on suggestions offered by various manufacturers and from a consideration of these the committee proposes the following two-years' course to be given by the electrical departments of steel plants:

First Year: Shop mathematics, magnetism, line and resistance calculations, diagrams and blueprint reading, d.c. machinery, motors and generators, a.c. machinery, motors and generators, inside wiring, conduit work, automatic control, and methods of braking.

Second year: Power-station layouts, switchboards and wir-

ing of same; and laboratory work comprising a conduit job complete, meter repairing and testing, motor testing and connecting, automatic control boards, curve-drawing instruments, illumination tests and calculations, meter transformers and connections, and armature winding.

A paper by D. D. Pendleton presented some considerations on Condensers and Condenser Engineering Practice, in which was a very good summary of well-known principles applying to the selection of condenser equipment and its installation and use.

A great deal of discussion was brought out by a paper on Automatic Engine Stops by Walter Greenwood. He held that automatic stops could well be extended to blast-furnace engines and to other types in mill work where they would prevent wrecks.

H. H. McLain discussed Bridge Motors for Overhead Cranes. An abstract of his paper is given in this number.

Denver Meeting of the American Institute of Mining Engineers

The 117th meeting of the American Institute of Mining Engineers was held at Denver and Colorado Springs, September 1 to 6. During the meeting many trips were made to points of interest including the electric ferromanganese furnaces of the Iron Mountain Alloy Company at Utah Junction, which it is said are being used experimentally for war purposes preparatory to larger developments; to the mining interests at Cripple Creek and Pueblo and to the works of the Colorado Fuel and Iron Company at Minnequa. This latter plant has enormous by-product coke-oven capacity and Bessemer and open-hearth furnaces and is heavily engaged upon war work. Some 6000 men are employed and the maximum monthly production of steel has reached 55,000 tons.

The papers presented at the several sessions for the most part were in the field of metallurgy and highly technical. The following titles are of greatest interest to the mechanical engineer: The Manufacture of Ferro Alloys in the Electric Furnace, R. M. Keeney (reviewed in this number); The Metallography of Tungsten, Zay Jeffries; The By-Product Coke Oven and Its Products, Wm. H. Blauvelt; The Use of Coal in Pulverized Form, H. R. Collins; Carbocoal, C. T. Malcolmson; Price Fixing of Bituminous Coal by the U. S. Fuel Administration, Cyrus Garnsey, R. V. Norris and J. H. Allport; Radium, R. B. Moore; Engineering Problems Encountered During Recent Mine Fire at Utah-Apex Mine, Bingham Canyon, Utah, V. S. Rood and J. A. Norden; Gaging and Storage of Oil in the Mid-Continent Field, O. U. Bradley.

During the convention a memorial service was held for the late Dr. James Douglas, former president of the Institute, an account of whose life appeared in THE JOURNAL for August 1918. In opening the meeting, President Sidney J. Jennings said that Dr. Douglas was an engineer, a scientist, a litterateur with a charming sense of style, a benefactor with a singularly wide variety of interests, and a man who had acquired wisdom and understanding, which surpass very great riches. E. P. Matthewson spoke of Dr. Douglas' Canadian associations and of his benevolence toward educational institutions of Canada; McGill University was highly favored by Dr. Douglas, and Queens University, from which latter he graduated. Altogether, the sums given by him to Canadian institutions would be probably up in the millions, but he was so retiring in his disposition that he seldom allowed his name to be used in connection with these matters. He also referred to the broadmindedness of Dr. Douglas in introducing the open door into metallurgy, by allowing every one to come to the plant and visit the mines with which he was connected, contrary to the usual policy of metallurgists.

W. R. Ingalls told of the well-merited business and financial success of Dr. Douglas, a remarkable feature of which was that he did not fully attain to these until nearly 50 years of age. Although he lived to the age of 81, his great accomplishments were achieved during the late years of his life. Although a captain of industry, his habits were simple and his mind was absorbed mainly in those studies most directly affecting the welfare of humanity.

A memorial service was also held in honor of the 15 members of the Institute known to have made the supreme sacrifice in the war. A service flag of the Institute showing 845 in service hung from the stage and as Secretary Stoughton read the records of those who had died in service, their pictures were thrown upon the screen.

Besides the professional sessions, the program included many interesting features, on the list of which was a banquet at Colorado Springs with the State Food Administrator as toastmaster. Among the speakers was Capt. Louis Benett, representative of André Tardieu, French High Commissioner to the United States, who won his audience by stating that the present need is not for transportation or food but "to put as many tons of steel as you have on the heads of your enemy."

At other times motion pictures were also shown, one being a Canadian film showing the adaptation to industry of soldiers crippled or disabled in the war, and another, a series of pictures showing mining and milling methods and welfare work by the Inspiration Consolidated Copper Company at Inspiration, Ariz.

Other Societies

At an enthusiastic meeting of the American Society of Marine Draftsmen, held in Philadelphia, June 29, Joseph A. Steinmetz, Mem.Am.Soc.M.E., S.A.E., Member National Research Council, Engineering Division, Member Submarine Defense Association, generously offered a cash prize of $50 to the member of the American Society of Marine Draftsmen who contributed the most original and practical paper on The Defense of Vessels Against Submarine Attack. In this connection it is interesting to note that at the December 11, 1917, meeting of the Philadelphia Section of this Society, Mr. Steinmetz presented a paper on Offensive Against the Submarine, with annotations to the suggestions to inventors made by the Naval Consulting Board of the United States regarding the submarine and kindred problems. This paper appeared in abstract in THE JOURNAL of March 1918.

At a "Win-the-War" convention of the New England Water Works Association, held at Boston, Mass., September 11, Mr. Charles T. Main, President Am.Soc.M.E., presented a paper on the fuel situation in New England, in which he said that water-works plants using fuel or purchased power might well form a Fuel and Power Committee similar to those established in manufacturing plants. Another speaker estimated that in a total of 155 cities canvassed a saving of one per cent of water through reduction of leakage or otherwise would mean an annual saving of 5200 tons of coal.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

For Articles on Subjects Relating to the War, see Aeronautics, Engineering Materials, Machine Tools, Munitions, Varia

Air Machinery (See also Lubrication)

TEST OF TIRE PUMPS. A test has been made at the testing laboratory of the Automobile Club of America in New York of the Cassco power tire pump, mainly for the purpose of determining the time required for inflating different sizes of tires to certain definite pressures and also the power required for operating the pump.

The pump has a single cylinder, the cylinder and crankcase being of cast iron in two parts with a fiber gasket placed between them. It has a 2.5-in. bore and a 15/16-in. stroke.

The article gives the data expressed in the form of curves. The figures for the horsepower determinations are not claimed to be correct, as the power consumed was very small in comparison with the size of the dynamometer. (*Automotive Industries*, vol. 39, no. 6, August 8, 1918, p. 243, 1 fig., *e*)

Engineering Materials (See also Hoisting and Conveying)

THE METALLOGRAPHY AND HEAT TREATMENT OF METALS USED IN AEROPLANE CONSTRUCTION, F. Grotts. The second installment of a very interesting article, a complete abstract of which will be given in an early issue. In the present issue special attention is called to the part dealing with the analysis of crankshaft material. Crankshafts made of chrome-nickel steel often contain hair lines or inclusions of manganese sulphide and silicate. They are objectionable due to the fact that they form surface cracks that will have a destroying effect on soft-metal bearings and also form slight lines of weakness. A number of such shafts were investigated with the following results.

Some shafts have stood up very well after a 100-hour run, while others show that cracks have begun to grow from the inclusions and still others have failed entirely, the failure being traced to the inclusions. As these inclusions can be avoided, and since they are unquestionably lines of weakness and do cause failures, why argue over their acceptance?

Hair lines are sometimes traced from quenching in cold water. Sometimes they are started by improper forging (forging strain). Heat treatment when not conducted properly will give a bad shaft. Variance of temperature in the furnace and crude quenching methods are the principal factors. Some pyrometers are found to be incorrect as much as 200 to 300 deg. fahr. Too much attention cannot be paid to the proper treatment of crankshafts. The gas pockets shown may be secondary pipes and the cracks connecting the pockets may be pipe cracks (expansion and contraction). A pipe generally can be removed by properly discarding the top section of the ingot, by bottom pouring, or by the use of molds having a greater top diameter than bottom. In the case of green steel there are local gas pockets.

Snowflakes occur in this steel because of poor mill practice. The manufacturer in trying to rush the heat sometimes pours while green. Furthermore, if a high-nickel bar of this steel be forged at too low a temperature there might be a condition such as this. The author prefers to think that the fault herein shown traces its origin to poor mill practice. (*Chemical and Metallurgical Engineering*, vol. 19, no. 4, August 15, 1918, pp. 191-197, illustrated, *eA*)

THE MANUFACTURE OF FERRO ALLOYS IN THE ELECTRIC FURNACES, Robt. M. Keeney. A very extensive paper not suitable for abstracting. It covers in considerable detail the methods of operation in several plants producing ferrochromium, ferromanganese, ferromolybdenum, ferrotungsten, ferrovanadium and ferrouranium. The most interesting part of the paper for mechanical engineers is that referring to ferrouranium, a material about which there is still a certain amount of uncertainty.

It is stated that ferrouranium was developed not because of any particular need for uranium in steel manufacture, but because of the large quantity of sodium uranate that was accumulating as a by-product of radium production. Considerable difficulties were encountered due to the tendency of uranium to form carbides, and also because of the strong affinity of uranium for oxygen, which makes uranium oxides quite stable.

A considerable amount of experimentation has shown that it is apparently impossible to produce a ferrouranium containing 30 per cent uranium with less than 3 per cent carbon. Therefore experiments were made on producing as high a uranium alloy as possible by using uranium metal. However, a new difficulty was encountered here, that of producing uranium metal. Among other things, these experiments showed the ease with which metallic uranium oxidizes.

A method to develop uranium metal was finally developed by using uranium oxide and petroleum coke. The uranium metal made in this way contained 93.0 per cent uranium, carbon 4.39, silica 1.43, iron 1.35, vanadium 1.31, phosphorus 0.051, sulphur 0.013.

Tests were also made on addition of uranium metal to steel in a tilting Siemens furnace lined with magnesite. It was found that uranium metal is not a satisfactory agent for the addition of uranium to steel for these reasons: First, it has such a high melting point that if it is added to the steel in the furnace just before pouring in the ladle all of the metal is not melted and only a comparatively small proportion enters the steel; in the second place, when it is left in the steel bath for a period long enough to melt it, it passes into the slag and oxidizes so easily that no uranium is recovered in the steel.

Experiments were also made on the production of uranium steel and by the addition of ferrouranium to molten steel. The results were not conclusive. (*Bulletin of the American Institute of Mining Engineers*, no. 140, August 1918, pp. 1321-1373, *eA*)

Foundry

Exceptional Gang Core Boxes, J. V. Hunter. A gang core box used to be one which produced a few identical cores at each operation. Recently a further advance has been made, and now instead of producing a single row or two of cores to lay out on the baking plate at one time, production has been increased to making a whole plateful of cores each time that the gang box is filled. This method makes the labor involved simply one of carrying to and moving from the ovens large numbers of plates of cores.

The article shows such core boxes and the manner of making them and describes in detail the operations.

It was a comparatively simple thing to develop the gang-type core box for simple cores, but the application of this method to the production of cylindrical and other shapes, such as are usually made in halves, proved to be a much more difficult proposition. To make a gang box for either half separately would be a simple matter, but to make them so that the edges would match exactly at all points when the plates were closed caused considerable trouble.

The writer describes in detail how this problem has been solved, with the result that now a few simple operations performed with great rapidity by an experienced workman produce at each cycle a full plate of cores, which by former methods would have been made up singly in halves, baked in two separate units, then laboriously pasted together and the edges dressed up. The article is of undoubted interest in furnishing considerable information on one of the recent developments in American foundry practice. (*American Machinist*, vol. 49, no. 9, August 29, 1918, pp. 377-380, 10 figs., *dA*)

The Fluidity of Molten Cast Iron, Matthew Riddell. The title chosen for this paper is claimed to be one which is meant to cover the expression of a view of the functions and operations of the cupola, which, in the author's opinion, has not been publicly discussed before.

The fluidity of cast iron is stated to depend on the amount of superheat or number of degrees of temperature over and above its freezing temperature that has been imparted to it in the cupola. The greater the superheat the greater will be the fluidity, and, other things being equal, the longer will it remain fluid to fill up the intricacies of the mold.

When the metal runs dull from the cupola various reasons are suggested, among them being lack of sufficient supply of coke. Up to a certain extent additions of coke will help, but repeated experience shows that after a certain limit of coke has been reached in the large, further additions appear to make the metal duller instead of more fluid. Another peculiarity of cupola operation is to which the writer calls attention is that better results are obtained in the way of hot metal when the bed coke is not well lighted above the tuyeres before the blast is put on and the first iron takes longer to come down than when opposite conditions prevail.

The writer bases his theory on the following:

First, that an iron which is very low in combined carbon, although high in total carbon, cannot be melted until a very high temperature is reached and consequently the liquid metal will be extremely hot. Further, in the course of melting the free graphite is rapidly dissolved and enters into solution of the iron with the result that the molten mass has a high percentage of combined carbon and, therefore, a low freezing point. Under such conditions an iron which will not melt until it has been heated to, say, 1400 deg. cent., does not freeze again until the temperature has fallen to about 1130 deg., so that such a metal may be said to have 270 deg. of life and will appear fluid.

The temperature which will be attained in the process of melting is determined by the amount of carbon in solution at the time the metal enters the melting zone and not that of the original iron charged into the cupola. Hence, in order to obtain the hottest melted metal it is essential to get the unmelted iron into the melting zone as quickly as possible. When the metal is held above the melting zone through excessive coke in the charges, the iron is afforded an opportunity to dissolve the graphite with the result that the material enters the zone with a lower melting temperature than it otherwise would have had. On the other hand, if the first charge is resting on coke which is not yet alight when the blast is turned on, its combined carbon is unchanged and the quick combustion of the coke by the blast raises the maximum temperature in the cupola before the absorption of graphite has been able to proceed very far.

In his conclusions the writer emphasizes the fact that the cupola is not suited to directly impart superheat or fluidity to any material which is being melted therein. He claims that while the freezing temperature of foundry iron may for all practical purposes be taken as constant, namely, at about 1130 deg. cent., the melting temperature varies and is regulated by the amount of carbon in combination or solution when the material enters the melting zone. (Paper before the British Foundrymen's Association meeting at Sheffield, June 1918, abstracted through *Foundry Trade Journal*, vol. 20, no. 199, July 1918, pp. 364-366, 1 fig., *g*)

Accuracy in Setting Cores, J. V. Hunter. In a great majority of cases cores in molds are supported entirely by the sand. Sometimes, however, they require greater accuracy in the setting than can be obtained by supporting the cores in sand.

Thus, in the present article is described the manufacture of cast-iron tanks used under about 30 lb. steam pressure on car-heating systems. Trouble was experienced from leakage about the chaplets required to hold the core in position. The chaplets were of the long-spike type, quite heavy and extending through the top of the core to a special blocking arrangement on top of the mold, and the metal would not burn into these chaplets.

To cope with this and other troubles it was decided to support the core directly from the walls of the flask by means of a pipe extending through the core, this pipe serving for the removal of gas. The article describes in detail how this was done.

A somewhat similar problem had to be solved by a concern manufacturing small steam engines used for driving winches

and cable hoists. The quantity of identical units was large, and the boring out of the piston head and getting the rod in place required a large amount of time. For this reason it was decided to cast the rod into the head, thereby not only saving time, but also insuring a head that would not work loose on the rod.

Further, to have the head in perfect balance without finishing all over, it was necessary to set the rod in such a manner that there should be no opportunity for it to shift.

A core had previously been used to inclose a portion of the casting which was provided with the hole *A*, Fig. 1, the exact

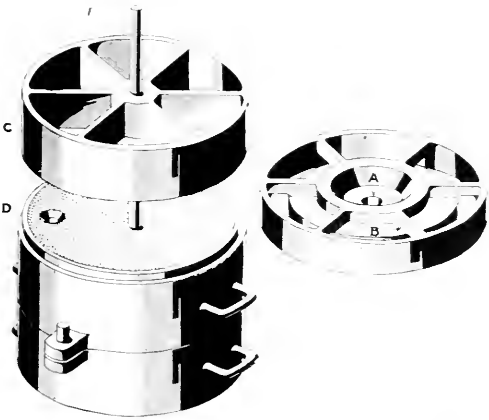

Fig. 1 Casting-in a Rod in Small Steam-Engine Piston

size of the rod, and the iron setting frame *B* made to guide the core into position in the mold.

The mold was made in a manner similar to that for the tank, being provided with a match board for the pattern that held the latter in a certain position in relation to a finished rim of the flask. The core is set by using the frame *B* to guide it into the same position relative to the finished edge of the flask as that occupied by the pattern.

The piston rod is inserted in the core, and the cope rammed about it and around the core which covers the pattern cavity below. During the ramming, and later, during the pouring of the casting, the piston rod is accurately held in a vertical position by the frame *C*, which is bored out on its lower rim to fit over the finished rim *D* on the upper edge of the cope flask. The center is bored to a close fit on the piston rod. The amount of preparation necessary to carry through this piston-head casting operation was inconsiderable and the results obtained were remarkably accurate. (*American Machinist*, vol. 49, no. 10, September 5, 1918, pp. 439-440, 3 figs., *dp*)

Fuel and Firing

Boiler Furnaces and Boiler Furnace Design, Dr. D. S. Jacobus, Mem.Am.Soc.M.E. A careful analysis of the factors affecting the efficiency of boiler furnaces, particularly with regard to those operated under steady load conditions.

The following fundamental elements in design were brought out: In the first place, enough draft must be provided to draw the products of combustion through the furnace and provide a draft suction under all conditions within the setting. Some suction should exist within all points of the setting irrespective of how hard the boiler must be driven. The next thing is to avoid a construction in which the brickwork is heated on both sides when under too great a stress (which particularly applies to the arch). Torchlike action of the flames on the walls should also be guarded against. This latter produces erosion and is apparently occurring more often with some classes of fuel than with others.

The above requirements, if satisfied, will give a furnace that will stand up. The next thing is to make it economical and this means one that will operate economically not on a short run, but under steady load conditions for long periods.

To make the furnace economical one must watch out first for excess air and then for carbon monoxide, and in this latter connection the author points out that the amount of carbon monoxide is frequently determined erroneously.

Under certain conditions it may be necessary to admit air above the fire. Hence the furnace should have such a volume and such a shape as to cause the combustible gases to mingle with the excess air.

In general, in a well-designed furnace there must be a way provided for unburned gases which come from one part of the fire to mingle with the excess air from another part of the fire.

Another feature in furnace economy is the burning out of the ash. Here care should be used since on one hand any loss of carbon in the ash counts against efficiency, but, on the other hand, one must guard against the endeavor to burn out the ash too clean at the expense of having too much excess air.

The questions of powdered-coal burning and oil fuel were also briefly touched upon by the author. (Paper before the American Boiler Manufacturers' Association, June 17, 1918, abstracted through *Power*, vol. 48, no. 9, August 27, 1918, pp. 318-320, *gp*)

Air Screens for Ovens and Furnaces, F. Wellman. Workers are greatly inconvenienced by the heat radiated from ovens and furnaces, which results in the necessity of changing the working shifts frequently and induces the workmen to refrain from examining the glowing material more than is absolutely necessary. The ill effects are somewhat mitigated by the use of hollow furnace doors cooled with cold water, but this means is only of any use when the furnaces are closed, and does not afford any protection when the doors are open for inserting or removing parts. Another method that gives partial relief consists in drawing off the hot air in front of the furnace opening by centrifugal exhausters. This method is open to the drawback that when a workman approaches the oven closely the transition of temperature is all the more sudden, and on this account more dangerous to his health. The best method to use consists in installing immediately behind the furnace door, and between the door and the furnace, a narrow slit through which cold air is blown upwards, so as to interpose a screen of air between the furnace and the door. This arrangement is found to give very good protection, and has the further advantage that flames are prevented from being forced out of the doors when they are opened, so that the workmen may operate without the use of very long tongs. The cool air has the further good effect of generally ventilating the shop in which the furnaces are placed.

Drawings and photographs of this arrangement are given, and it is explained that it is of importance that the air should emerge from all parts of the slit with the same velocity. An air-screening arrangement, manufactured by Wener Geub, Cologne, for a large steel foundry is described in some detail. The slit is only 6 mm. wide, and the air is forced out at a great velocity. Measurements showed that the velocity of the air was about 15 m. a second at 500 mm. distance from the open-

ings of the slit, and 7.9 m. a second at 1000 mm. distance. Further measurements showed that the velocity all along the slit was nearly constant. The air is driven by a high-pressure ventilator drawing from the open air. This ventilator is capable of drawing 64 cu. m. of air per minute, and is driven by a 12-hp. motor which delivers the air at a pressure of 465 mm. (water column). Further installations of a similar nature are described, and it is concluded that this type of protection should be extensively used. (*Zeitschrift des Vereines deutscher Ingenieure,* abstracted in *Page's Engineering Weekly,* vol. 33, no. 727, August 16, 1918, p. 79, *d*)

Tars Distilled from Bituminous Coal in Hand-Fired Furnaces, S. H. Katz. A paper recording results of tests made as a part of the comprehensive investigation of combustion in furnaces that is being conducted by the Bureau of Mines. It deals especially with the liquid or tar part, at ordinary temperatures, of the volatile matter evolved in a coal fire.

Three samples of such tar were examined and the results show that in the hottest fires the volatile matter evolved by the coal is the same as the so-called "primary volatile products of coal." This matter, after it is produced, yields oxides of carbon and water vapor by burning, and by cracking forms end products, i.e., carbon or soot and fixed gases. The two processes should be considered as acting at the same time and coördinately. The paper describes in detail the equipment used and the method of carrying out the tests. The results are presented in the form of tables.

It appears that the greatest proportion of tar vapors exists at the surface of the burning coal, while in the plane 1 ft. above the bed practically no tar remains, no matter what the excess of air mixed with the combustible gases above the bed.

On the basis of experimental evidence the investigator came to the conclusion that tars can exist in the fires of a hot furnace burning bituminous coal for a period that is less than 0.1 sec. The following conclusions are also of interest:

When bituminous coal in quantities to last for a period of hours is added to a slowly burning fire, tar may be found in the gases within the fuel bed through a considerable part of the time the coal is burning. When coal is added to fires in uniform quantities and at short, regular intervals, the greatest quantity of tar in the gases is at the surface of the bed.

Naphthalene and anthracene, which, at intermediate temperatures, are characteristic of the thermal decomposition of the primary volatile matter of coal, were absent from the tars collected.

It is probable that, at the high temperatures of flames, the tars that escape burning are decomposed directly to soot and fixed gases; that is, without formation of hydrocarbons such as naphthalene and anthracene, which are produced as intermediates, at least in part, at lower temperatures.

Decomposition of all the unburned tars in hot fires to soot and fixed gases occurs in less than 0.1 sec. (*U. S. Bureau of Mines Technical Paper* 195, March 1918, 17 pp. 3 figs., *e A*)

Furnaces

Graf Gas-Consuming Furnace, John Nelson. The aim in the design of this furnace was to secure the combustion of the gases which ordinarily are wasted in the operation of power boilers and pass off in the form of smoke. It has been in practical operation on a battery of Stewart boilers developing upward of 1700 hp. The plant records are said to indicate reduced fuel consumption of about 25 per cent, using bituminous coal.

The operation of the furnace is based on the introduction at the top of the bridge wall of the furnace of preheated air impelled at high velocity by a steam jet. This results in a complete intermixture of air and flue gases at a point of highest temperature, the result being a series of reactions in which escaping carbon monoxide and free carbon, together with the hydrocarbons are converted into carbon dioxide.

The ordinary bridge-wall form is discarded, and instead of a straight horizontal top, the wall is curved as an inverted arch, the arc corresponding to that of the boiler shell. It is claimed that a more uniform flow of gases from the firebox along the circumference is obtained. The air is introduced into the furnace through a 4-in. pipe which is brought down

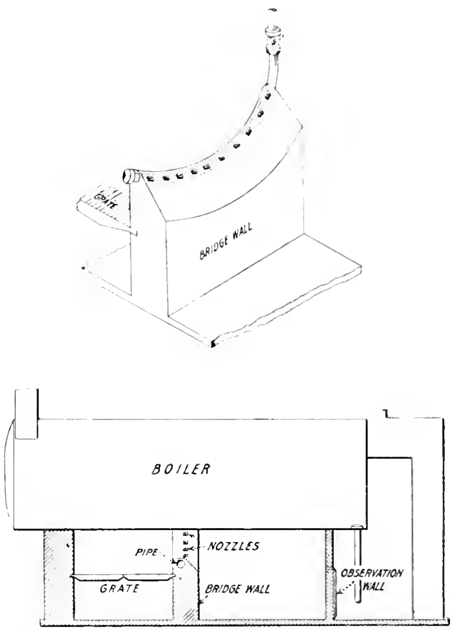

Fig. 2 Some Details of the Graf Furnace

through the masonry of the side wall and is curved to conform with the arch of the bridge wall in which it is imbedded. The actual entrance of the air into the chamber is through a series of nozzles (Fig. 2). As shown in the figure, the lower interior wall of the nozzle is given an even, gentle curve, which serves to facilitate and guide the flow of air. The nozzles are so spaced that their jets combine at a point about 6 in. above the bridge wall to form a solid stream of air covering the complete width of the furnace. The nozzles are set at an angle of 70 deg. in the direction in which the gases flow. The air is delivered by a steam jet. The steam is admitted through a nozzle $\frac{1}{16}$ in. in diameter. The vacuum is created by the steam sucking in an amount of air which is proportional to the volume of steam used. The steam serves a double purpose of preheating the air and of giving a velocity sufficient to produce a complete intermixture with the flue gases.

Tests made at the Worcester Polytechnic Institute demonstrated a complete absence of carbon monoxide in the flues, as well as a minimum of free carbon. The observation doors reveal a condition of apparently full incandescence in the

combustion chamber, even immediately after stoking. (*The Iron Age*, vol. 102, no. 6, August 8, 1918, p. 339, 1 fig., *d*)

Hoisting and Conveying

A Safe-Load Chart for Rope Slings, F. W. Salmon, Mem.Am.Soc.M.E. A chart intended to meet the requirements of practical men. A card, Fig. 3, about 3.5 by 6 in., is divided around the edge as a protractor, every 10 deg. being marked with a plain black triangle. In the center space appears a chart of the safe loads based upon the particular kinds and sizes of slings that are used in the shop. Upon the back of the card may be printed directions for its use.

When an unusual load is to be lifted, the foreman can hold the card in the manner shown in Fig. 4, and when the sling just becomes taut he can estimate the angle to about the nearest degree. Having the total weight to be lifted, he can instantly determine whether or not the sling is safe to handle the load. (*American Machinist*, vol. 49, no. 6, August 8, 1918, p. 242, 2 figs., *p*)

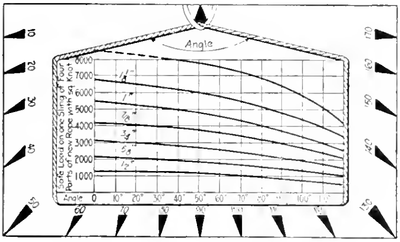

Fig. 3 Load Chart for Rope Slings

Bridge Motors for Overhead Traveling Cranes, R. H. McLain. Discussion of the factors affecting the selection of sizes of motor and gear ratio for bridge motion of overhead traveling cranes.

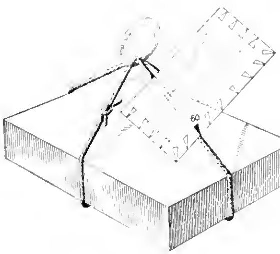

Fig. 4 Manner of Using the Chart in Fig. 3

The author analyzes the work done by the bridge motor and states that four things which tend to limit the rate of its acceleration. They are as follows:

Automatic magnetic control can absolutely limit it;
Slipping of wheels can partially limit it;
Swinging of load can limit it in some cases, and finally
It may be limited through considerations for the comfort of the operator.

An average acceleration of something like 1 to 1½ ft. per sec. per sec. will be fast enough for cranes which travel at less than 500 ft. per min. or make infrequent starts. Cranes which make regular frequent trips of 50 to 60 ft. every minute or so may need an average acceleration of 2 to 2½ ft. per sec. per sec. and special cranes handling heavy swinging loads may need still higher peak accelerations.

The motor is always out of danger when it is powerful enough to slip the wheels under full load without exceeding its working limits, and the practical way of protecting the motor is to have the crane do its work with only a quarter of the wheels driven, where it is possible to do so.

The swinging of the load will, in some cases, have a great deal to do with the rate of acceleration, and, for example, when the load is hung from the crane by a flexible rope, the motor is relieved somewhat, as it does not have to start the load as soon as the crane starts.

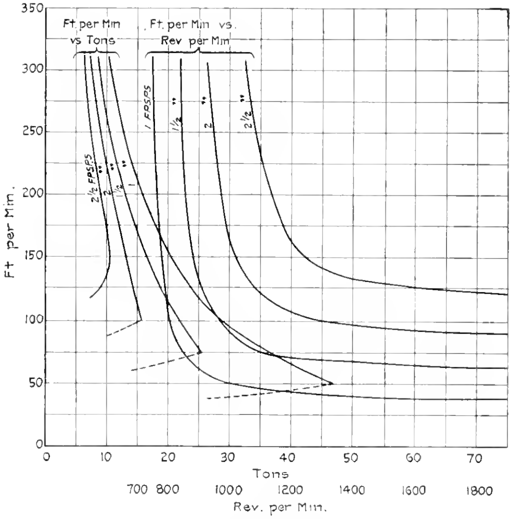

Fig. 5 Acceleration Chart for Overhead Traveling Crane Bridge Motors

The discomfort of the operator becomes an important factor where manual control is used, rough material is being handled and half of the wheels are driven. In order to get data on the subject, the author asked several manufacturers to send him test data on their cranes. These data show a variation in the peak rates of acceleration in feet per second per second from 0.54 to 3.09 for empty cranes and 0.348 to 1.85 for loaded cranes, the weights of the complete cranes in pounds being, respectively, 90,000 and 320,000.

The table covers the range of cranes with rated loads from 10 tons to 100 tons, and shows quite wide variation within the limits indicated above of the peak rates of acceleration. The author gives a formula for calculating the rate of acceleration with or without load used in compiling the table referred to above.

It is claimed that the rate of acceleration is absolutely as important as the final speed of the crane in determining the sizes of motor for a crane. In order to show what a given motor may do under various conditions of load, speed and rate of acceleration without exceeding its working limit, the author prepared Fig. 5. While calculated on several assumptions which may not be altogether correct, the curve gives a basis

for comparing conditions. These assumptions are that rolling friction of crane is 50 lb. per ton, and that there are no gear losses between the motor and the track. The maximum peak torque allowable at the motor shaft is taken at 78 lb-ft. The total flywheel effect of motor, armature, brake, wheel and gears is taken as 8.4 lb. at 1 ft. radius on armature shaft.

The way to use Fig. 5 is as follows: Suppose a 12.5 ton loaded crane is being considered and a rate of acceleration of 2 ft. per sec. per sec. is desired. Then read up from 12.5 tons to the curve marked "2 ft. per sec. per sec." The intersection is at 170 f.p.m. Then read across from 170 f.p.m. to f.p.m. vs. r.p.m. curve marked "2 ft. per sec. per sec." The intersection is at 995 r.p.m. This indicates that the motor should be geared so that 995 r.p.m. corresponds to 170 f.p.m., and that when so geared it can start 12.5 tons at 2 ft. per second per second peak acceleration without exceeding 78 lb-ft. torque on the motor shaft.

The writer recommends that if automatic magnetic control is going to be used on the crane, an acceleration should be adopted of 2 ft. per sec. per sec. for all cranes except those which have swinging loads or which make very short, rapid trips of something like 50 or 60 ft. per min. when a peak acceleration of 3 ft. per sec. per sec. should be used. If, however, only a quarter of the wheels are driven, the peak acceleration may, in all cases, remain not higher than 2 ft. per sec. per sec.

With manual control a peak acceleration of 1 to 3 ft. per sec. per sec. should be used, depending on the nature of the work. For power-house and stand-by cranes, 1 ft. per sec. per sec. is ample; for hot-metal ladle cranes 3 ft. per sec. per sec.; and for busy loading cranes 2 to 3 ft. per sec. per sec. (Paper before the Twelfth Annual Convention of the Association of Iron and Steel Electrical Engineers, Baltimore, September 1918, abstracted from an advance publication, 9 pp., 2 figs., *pg*)

Hydraulic Engineering

Hydraulic Accumulator Protective Valve. Description of a new type of valve designed to protect large accumulator systems.

The valve is installed directly at the pipe outlet of the accumulator with a pilot-line connection to some distant point of the piping system. The pressure of the liquid from the pump lifts the main check and charges the accumulator. At the same time the plunger in the cylinder is raised, thus holding the main check off its seat irrespective of whether the accumulator is being charged or discharged, as long as the pressure of the pilot line is maintained. If a break should occur in the piping system, the pressure is immediately lowered, and this loss of pressure in the pilot line and small cylinder is overcome by a spring permitting the plunger to drop.

Hence, as long as the pressure is maintained in the system the liquid flows freely, but if the pressure should be lowered for any reason the main check valve is seated, which prevents falling of the accumulator. (*The Iron Age*, vol. 102, no. 7, August 15, 1918, p. 389, 1 fig., *d*)

Internal-Combustion Engineering

The Diesel Motor Injection Valve, W. Stremme. (*Zeits. Vereines Deutsch. Ing.* 62, pp. 111-115, March 9, 1918.) The influence of the injection valve on the injection performance is considered, and it is shown that the nozzle opening is the basis of standardization. Standardization is quite feasible and is essential to the bulk production of Diesel motors. Charts are given showing standardized and unstandardized values of nozzle and needle diameters, etc., for Diesel engines ranging from 25 to 200 hp. per cylinder. One important advantage of standardization would be the easier obtaining of perfect combustion without repeated trials and adjustments on individual engines. (Taken from *Science Abstracts,* Section B—Electrical Engineering, vol. 21, pt. 7, no. 247, July 31, 1918, p. 250, *g*)

Independently Driven Circulating Pumps for Jacket Water. In the case of oil engines, particularly those of the Diesel type, the pressures in the cylinders are very great, necessitating the use of heavy cylinders and pistons. There is, therefore, a large amount of metal present and a considerable amount of heat stored therein.

When the engine is shut down after a period of full load and the water circulation simultaneously ceases, enough heat is still stored up in the metal to evaporate the hot water in the jacket and leave an excess. This excess is conducted through the walls into connected parts that were not designed to withstand temperature stresses and as a consequence they are strained or cracked.

The suggestion is made that an independently driven pump should be used instead of a direct-connected pump, so that the pump may be kept running after the engine has stopped until all the heat is removed and the metal is cooled to a normal temperature. (*Power,* vol. 48, no. 7, August 13, 1918, p. 238, *p*)

Gile Sub-Piston Engine. Description of a two-stroke engine having, in addition to its regular working piston, a sub-piston in each cylinder, operated from a special crank on the crankshaft.

During the power stroke the main and sub-piston both travel in the same direction and at substantially the same rate of speed. This continues until they have reached a point where the main crank is within 45 deg. of the bottom dead center, at which point the exhaust valve begins to open. As soon as the exhaust valve opens the sub-piston is gradually stopped by a rocker-arm movement and is then started on its return stroke, during which it scavenges the cylinder of the burned gases and at the same time draws in a fresh charge of gas from the carburetor through the intake ports in the cylinder walls near the lower end of the stroke.

In the cylinder walls at the upper end there is a series of flutes which afford a passage for the gas in the space between the main piston and the sub-piston. It is claimed that the fuel in passing through these flutes is so thoroughly broken up that the engine can burn kerosene as readily as gasoline, no preheating of the fuel or air being required. (*Automotive Industries,* vol. 39, no. 6, August 8, 1918, pp. 229 and 238, 2 figs., *d*)

Lubrication

Lubrication of Air-Compressor Cylinders, W. H. Callan, Mem.Am.Soc.M.E. A résumé of experience with air-compressor cylinder lubrication in which it is claimed that the temperature of the inside of the cylinder wall of a water-jacketed cylinder is not more than 30 deg. fahr. higher than the temperature of the jacket water as long as the water does not boil.

In view of this condition, the writer claims that a light mineral oil should be used rather than oils of heavy grade and high flashpoint; further, that a pure mineral oil should be used, preferably one having a gravity of from 31 to 33 Baumé, a

flashpoint of 375 to 390 deg. fahr. and a viscosity of 140 to 150 Saybolt at 100 deg. fahr. (*Power*, vol. 48, no. 7, August 13, 1918, pp. 229-230, *g*)

Machine Shop

Emulsion Lubrication of Cutting Tools, J. A. De Cew. Discussion of the lubrication of cutting tools with special reference to their lubrication by materials in a state of emulsion.

If oil is mixed with a substance which is soluble in a large amount of water, and subjected to mechanical action, the oil is broken up into fine particles which float in water and thus produce what is known as an emulsion.

As the emulsifying agent is usually more expensive than oil, only enough of it is used to cause the emulsion to form. It is believed that as the oil particles in suspension came in contact with the hot tool surfaces, some of them are interposed between the parts in contact and thereby produce lubricating action.

The coarser oil particles are said to be prevented by their size from penetrating between the surfaces as far as the aqueous medium, but the finer particles which are microscopic in size follow the solvent and perform lubricating service.

If the compound is slowly stirred into water very white emulsions are likely to be produced, from which a portion of the oil will gradually separate if allowed to stand for a time, but if the compound is diluted in water by means of pressure, using special apparatus and proper temperatures so that instantaneous solution can take place, then the emulsifying agent may be diluted with water without breaking up its combination with the oil, and a diluted solution is obtained which resembles the original compound in character.

When such a solution of oil dries on a metallic surface, it leaves a film which acts as a protective coating against rust. (*American Machinist*, vol. 49, no. 10, September 5, 1918, pp. 433-434, *p*)

Using a Punch Press in Lieu of Bending Rolls, J. V. Hunter. Brief description of the way in which awkward and annoying jobs involving the bending and forming of sheet metal may be rendered simple and easy by means of a few cheaply made dies of hard wood used in the ordinary form of punch press to be found in any structural shop. The article is of considerable interest in that it calls attention to the possibilities of the use of wooden dies. (*American Machinist*, vol. 49, no. 6, August 8, 1918, pp. 243-245, 6 figs., *g*)

Electric Furnace for Heat-Treating of Small Aeroplane Parts, Dwight D. Miller. The article refers to the handling of nickel-steel parts and presents the subject from the point of view favorable to the electric furnace. The method of carrying on the heat-treating operations with such furnaces is described in detail. (*American Machinist*, vol. 49, no. 9, August 29, 1918, pp. 373-376, 2 figs., *p*)

Gas-Engine Work on the Pacific Coast, Frank A. Stanley, Mem.Am.Soc.M.E. Description of machine operations used in the shops of the Atlas Imperial Engine Company, of Oakland, Cal., in building stationary, portable, marine, hoisting, etc., engines.

The company builds units of one, two, three and four cylinders, ranging in capacity up to several hundred horsepower, and has, therefore, to arrange for performing a number of operations.

Fig. 6 shows the arrangement of the crankshaft bearings and base compartments, the bearings through the automatic ring oilers receiving the lubricant from a chamber below the shaft. The main bearings are of unusually great length, about ten times the diameter of the shaft.

The lower case for the crankcase proper is formed by a finished surface along the top of the base casting. The crankcase consists of an integral rectangular frame for enclosing all the

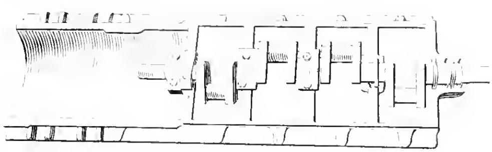

Fig. 6 Arrangement of Crankshaft Bearings and Base Compartments

working parts of the engine with the exception of the pistons and valves. The top of the crankcase is adapted to receive the cylinders, and each side of the case is fitted with doors to give easy access to the interior.

The cylinders are cast with heads as an integral part.

An interesting detail is shown in Fig. 7, namely, the reversing gear for use with marine engines. In this gear there are six pinions spaced about the central gear, all made from steel forgings and provided with bronze bushings. The entire set of gears is enclosed in an oiltight casing and runs in oil all the time. This gear arrangement is of interest, as it gives the propeller the same rate of speed astern as when running ahead.

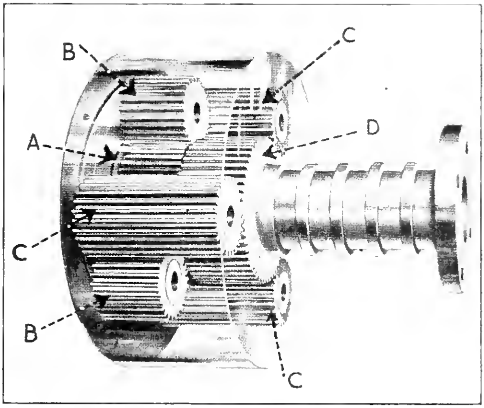

Fig. 7 Reversing Gear for the Atlas Imperial Engine Company Marine Engine

The go-ahead drive is by means of a friction clutch of the multiple-disk type, which admits of adjustment by loosening a single bolt and screwing around a clamp collar. The gear case is a plain cylindrical affair, which when the reverse lever is operated is prevented from rotating by a pair of clamp shoes, or brakes, which are actuated by a powerful screw-and-toggle motion; at the same time the friction is released.

The reverse drive is then through the gears and pinions as follows: The power from the engine is transmitted through the shaft to the spur gear *A*, which, when the case is prevented from turning by the clamps before mentioned, drives three short pinions *B* (two of which may be seen in the cut), and these drive the long pinions *C* which mesh with the gear *D* upon the propeller shaft. The reverse direction of rotation

therefore occurs between pinions B and C. (*American Machinist*, vol. 49, no. 8, August 22, 1918, pp. 343-347, 16 figs., *d*)

Reclaiming Oil from Metal Turnings, C. L. Smith. Description of a system for collecting steel turnings, recovering the cutting oil that usually clings to them, and loading them on cars, as used in the plant of the Cincinnati Milling Machine Company.

Receiving trucks are provided for conveying the turnings to the oil and scrap building, located about 100 ft. distant from the main plant. The design of the trucks is such as to eliminate the handling of the turnings as much as possible, and actually only two of these trucks operated by one man are needed for the entire plant.

The trucks are lined with sheet metal and the sheet covering the sloping bottom is perforated at the lower end to allow the oil drained from the turnings to pass into the tank located below. A 4-in. baffle plate is provided at the front to divert the oil into the receiving tank underneath, and at the top of the perforated section an oil splash guard is placed for the same purpose. Means are provided for easily draining and cleaning the oil tank and unloading the chips into the oil separator. The top of the separator is level with the floor which is preferable to one having the top located above the floor level.

For collecting the chips a specially shaped galvanized steel pan is used. This pan is placed on a small shop truck directly beneath the sliding door in the oil pan of the screw machines and the chips can be raked into it without spilling oil on the floor, which again is claimed to be preferable to the usual method of removing the turnings from the machine oil pan with a fork and putting them in a wheelbarrow.

After being filled the collecting pans on the shop trucks are carried to the rear of the shop where the receiving truck is stationed.

By the receiving truck and the elevators the turnings are delivered to a Tolhurst oil separator.

The dry chips are ultimately dumped into specially arranged concrete switch bins, therefrom to be loaded on cars. These bins have sloping bottoms and sheet-metal doors that are the full height of the bins. The bins are about 25 ft. apart so that a standard 40-ft. car can be loaded from both ends at the same time.

Records of the company show that the oil reclaimed from the turnings represent a really worth-while saving. In April 1918 3092 gal. were recovered, in May 2400 gal. and in June 1402 gal., the general average being about 100 gal. per working day. (*The Iron Age*, vol. 102, no. 10, September 5, 1918, pp. 558-559, 2 figs., *d*)

Sand-Blasting Machine, M. E. Hoag. In an article under the title Manufacturing the Comptometer, the writer, among other things, describes machines used for sand-blasting the comptometer parts.

One of such machines is shown in Fig. 8, built and designed for this special purpose. The body of the machine A carries a shaft and set of pulleys at each end, over which pass endless rubber belts for carrying the work under the blast nozzles. Under the machine is a hopper through which the spent sand runs by gravity to a switch bin, from which it is carried by elevators to a supply bin overhead. Sliding doors at B permit work to be held under the blast by hand and glass windows at C allow the workmen to watch the progress of the work without risk to eyes and lungs.

The sand runs from the overhead supply bin to the nozzles through the spout D to the gates E, which have screw adjustments and distribute the sand in a long, flat stream under the air nozzles F, and the opening in the machine body at G is closed by a canvas curtain and permits work being placed on the endless belts. The exhaust pipes H carry off the spent air and fine dust, leaving the returned sand always clean and ready for use. These machines use from 12 to 14 oz. air pressure. (*American Machinist*, vol. 49, no. 9, August 29, 1918, p. 391, 1 fig., *d*)

Machine Tools

Flush-Pin Versus Limit Gages, Albert H. Dowd. Description of several types of flush-pin gages, both for work and inspection, and a general discussion of the application of such gages.

Limit gages are not always reliable when the product is such that it must be kept within very close limits of accuracy. This is due to the fact that the ordinary go and no-go gages do not determine the fluctuations in the work sizes to any appreciable degree. The writer gives an example where with a

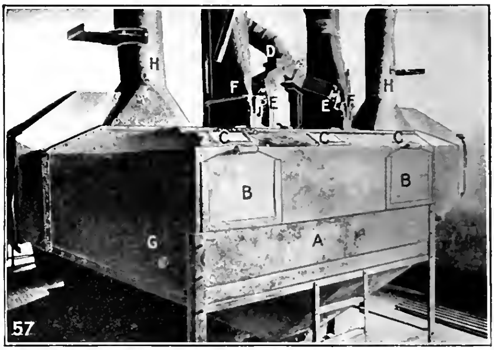

Fig. 8 Sand-Blasting Machine

go gage of 1.998 and no-go 2.001, a hole machined so that it actually measured 2.0005 would still pass inspection. Yet while the work would be verging close to the danger line, the operator would not be aware of it, except by the feel of the gage as he entered it in the hole. The very next piece of work might not pass the gage due to the wear of the tools, and if the operator were inclined to be careless, three or four pieces might need reboring before the error became apparent.

In boring and turning, plug and snap limit gages are used universally, but for gaging depth, shoulder distance and work of this kind, the writer believes that another type of gage should be considered, namely, one which will act as a limit gage and at the same time show the machine operator how closely he is approaching the danger line.

The flush-pin gage is of this type. It is used to considerable extent on gun work for close tolerances and can be made up at a reasonable price. In its simplest form it can be used for tolerances of about 0.005 in. or greater, and with additional refinements it can be made to indicate a fluctuation of 0.005 in. or even less.

The application of the flush-pin principle in gaging a piece of work during machining is shown in Fig. 9. In this case the work A must be machined so that depth B will be within a tolerance of 0.25 mm. This gage is on the same principle

as flush-pin gages generally, but as the work is recessed, provision is made in the shoulder G to roughly center the tool when placing it in the work. This facilitates the handling and roughly locates the flush pin against the face of the casting C. The registration of this gage is by means of the pin E,

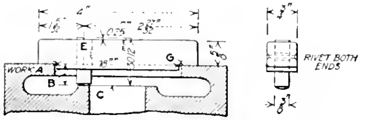

Fig. 9 Method of Using a Flush-Pin Gage

which is shouldered, as shown, to indicate the variations in the facing of the boss C.

The flush-pin principle can be applied to work requiring especially close tolerances by the addition of an indicator multiplying lever in connection with a suitably graduated scale. (*American Machinist*, vol. 49, no. 7, August 15, 1918, pp. 283-284, 5 figs., *dp*)

Metal-Concrete Planing Machine. In the June 1918 issue of The Journal (page 505) an abstract from the *American Machinist* was given describing a large planing machine with a concrete bed.

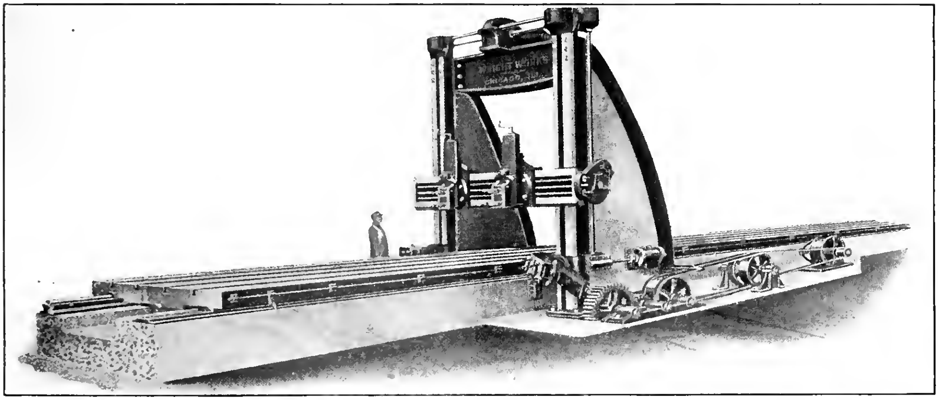

Fig. 10 Metal-Concrete Planing Machine

The present article briefly describes a similar machine developed by David A. Wright, of Chicago, and states that the machines are built in sizes ranging from 6 to 20 ft. with any length of bed. The platen of the machine is made of structural-steel sections, with inserted cast-iron T-slots (Fig. 10) in the upper surface and is filled with reinforced concrete. After the concrete filling has set and the platen is put in position on the machine, the upper surface is planed off. The ways on which the platen travels consist of a flat cast-iron one for the front and a piece of steel shafting for the rear one, both supported by concrete foundations. The frame of each side housing consists of three castings for the front, back and base, respectively. After these have been finished and assembled, concrete is poured in to provide rigidity. The feed is of the pneumatic type. (*The Iron Age*, vol. 102, no. 8, August 22, 1918, p. 449, 1 fig., *d*)

Sheet Corrugating and Curving Machines. Description of specially constructed machines for corrugating steel shelters for the United States Army.

These shelters are made of No. 11 gage sheet steel and are corrugated 4 in. deep by $12\frac{3}{4}$ in. center to center. The top and bottom of the corrugations are $5\frac{3}{4}$ in. wide each and the sides are on a 15 per cent angle. After being corrugated the sheets are curved to a 5-ft. radius on a machine, also specially designed for this purpose and described and illustrated in the original article.

The corrugating machine has semi-steel, hexagon-shaped, hollow-cored rolls, with cross-ribs running their entire length. The rolls are drilled and tapped for interchangeable dies, which are also of semi-steel, and the corrugations are machined out of the solid. The machine is 10 ft. high and weighs when assembled 85,000 lb.

The curving roll forms the sheets after they have passed through the corrugating machine. It occupies a oor space of $6\frac{1}{2}$ by 12 ft. and weighs 10,000 lb. (*The Iron Age*, vol. 102, no. 9, August 29, 1918, p. 501, 2 figs., *d*)

Measuring and Testing

A Comparison of Various Manometers, L. Holborn (*Ann. d. Physik*, 54.7., pp. 503-510, April 9, 1918. From the Physikal.-Techn. Reichsanstalt). For pressures higher than those suitable for the mercury manometer, there are several instruments on the market. These, in some instances, register pressures as high as 1000 kg./cm.². One form mentioned in detail is a differential manometer. The pressure is communicated by resin oil to the inside of a strong cylinder. Here it acts on a plunger, whose ends project from the cylinder, but whose center, in the cylinder, is slightly tapered.

The author points out the corrections necessary for change in dimensions of the metal due to the pressures. Two manometers compared over a range 100 kg./cm.² to 1000 kg./cm.² differed by 0.03 per cent at low pressures, but by only 0.01 per cent above 300 kg./cm.². Another manometer, less satisfactory, showed differences from each of the above of about 0.18 per cent. (Taken from *Science Abstracts*, Section A—Physics, vol. 21, pt. 7, no. 247, July 31, 1918, p. 281, *c*)

METHOD FOR TAKING MOVING PHOTOMICROGRAPHS. At the last annual meeting of the American Society of Testing Materials at Atlantic City (June 1918), considerable interest was aroused by the exhibition of moving photomicrographs by Prof. Herbert F. Moore of the University of Illinois, Urbana, Ill.

The moving photomicrographs shown represented the first successful attempt for recording the gradual changes in the structure of a metal when subjected to repeated bending stresses. The great possibilities of this method are, of course, obvious.

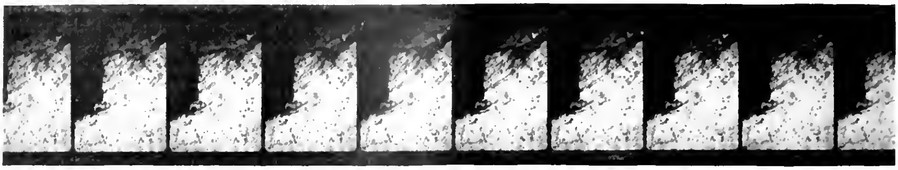

FIG. 11 STRIP OF PRINTS FROM FILM SHOWING DEVELOPMENT OF SMALL CRACKS OR SLIP LINES

The present article contains illustrations of the machine which was used to bring a wrought-iron test piece under repeated stress, as well as the apparatus used for taking the moving photomicrographs.

In Fig. 11 is shown a section of the original film early in the experiment. This is a strip of prints showing development of small cracks or slip lines with magnifications of about twenty times. These photographs were taken at the rate of sixteen per second, the exposure used being one-fiftieth of a second.

The original article also contains seven still photomicrographs showing the development of slip lines in a specimen of iron from the unstressed state to the finally developed crack. Fig. 12 is likewise of interest in reproducing a strip of prints from a film showing the various phases in the development of a large crack.

FIG. 12 STRIP OF PRINTS FROM FILM SHOWING DEVELOPMENT OF LARGE CRACKS

So far the moving-photomicrograph method has been applied only to wrought iron, because of the large crystals and distinct markings, and also because of its easy deformation under stress, but it is expected that ere long this method will be applied to steel and non-ferrous metals and alloys. It has been stated that this new device may determine just how steels begin to deteriorate under stress. In this way it may lead to new methods of heat treatment prolonging the life of certain steels and rendering them less liable to fatigue. In any event, it will give a much clearer insight than we have had hitherto into the actual growth of strain phenomena and ways they affect metal of various physical and chemical structures. (*The Iron Age*, vol. 102, no. 6, August 8, 1918, pp. 323-325, 10 figs., *d*)

Mechanics

CONCRETE BEAMS WITH FIXED ENDS. In many cases building ordinances make no provision for fixed ends of concrete beams. The design requirement for a single-span concrete beam supported on concrete columns at each end provides that the beam shall be designed for a moment of $WL/8$ at the center, which is approximately only for brick bearing walls, but is not true where the beam is supported by concrete columns more or less fixed to the beam, as little or no provision is made to allow for the bending to which the column must be subjected as a result of the rigid connection with the beam. This method of design provides a beam about 50 per cent too strong and may prove to be excessively weak in long-span construction columns. The present article gives the discussion of a fixed beam designed in reinforced concrete as applied in the construction of a factory building in Illinois.

The distribution of bending moments through the columns and beams was obtained by the method of slopes and deflections. In this method of analysis the bending moment is found in the beam at the intersection of the center lines of the column and mid-depth of the beam and in the column just above and below this intersection.

Fig. 13 shows the design used for one of the frames. In designing the columns for direct load and bending care must be taken in considering the column section just above the floor, as this is the critical point. This is due to the fact that this location is as high as anywhere in the columns, and, in addition, only the bare column section, without any bracket, is available to take up the stress.

The original article gives a complete calculation of the various moments. (*Engineering News-Record*, vol. 81, no. 8, August 22, 1918, pp. 359-361, 5 figs., *pA*)

Munitions

THE 75-MM. FIELD GUN, MODEL 1916, M. III. Special correspondence to the *American Machinist*, describing the latest

of the four types of 75-mm. field guns built by the United States Government. The article gives the length, weight and other data, and describes and illustrates the component parts of the breech-closing and firing mechanism.

The gun weighs 749 lb., has a total length of 90.9 in., and a right-hand twist constant from origin to muzzle. It can use either shrapnel or shell, the weight of the shrapnel being 15.96 lb. and the weight of the shell 12.36 lb.

A service pressure of 33,000 lb. per sq. in. is used. The mechanism is of the drop-block type and is semi-automatic, the block closing automatically when a round of ammunition is inserted.

A complete and interesting description is given of all features not involving elements of military secrecy. (*American Machinist*, vol. 49, no. 8, August 22, 1918, pp. 323-328, 4 figs. and table of nomenclature of the breech mechanism, *dA*)

Power Generation

Development of Power from the Standpoint of the Boiler Room, C. F. Hirshfeld, Mem.Am.Soc.M.E.. J. E. Aldred lecture on Engineering Practice at Johns Hopkins University.

The writer states that although only a small percentage of the latent heat contained in fuel is converted into electric energy there is comparatively little improvement to be hoped for in power plant economy, but there is a large and profitable field for betterment in the operating conditions of the *average* power plant. He emphasizes that in a boiler plant it is not the highest thermal efficiency but the highest possible commercial efficiency that is aimed at. He presents from this point of view an interesting study of the overall efficiency of a boiler showing how step by step the entire installation of a power plant is usually a compromise between various requirements. (Abstracted through *Power*, vol. 48, no. 8, August 20, 1918, pp. 284-286, 2 figs., *g*)

Power Plant

Boiler Equipment of the Auzberg Power Station, P. Koch. (*Zeits. f. Dampfkessel. u. Maschinenbetrieb*, No. 43, 1917. *Elektrot. u. Maschinenbau*, 36. p. 158, March 31, 1918. Abstract.) It was made a condition that the grates should burn Bohemian brown coal economically, and it was found by trial that the Piedboeuf chain grate was most suitable for this fuel. Four Burkhardt vertical-tube boilers are used, each of 400 m.^{2} heating surface and designed for 15 atmos. working pressure with superheater and wrought-iron economizer. Induced draft is provided, and the total grate surface of each boiler is 17.2 m.^{2} Flue ashes are caught in special spirals and removed below the boiler-house floor. The wrought-iron chimney is 29.5 m. high and 1500 mm. internal diameter. Butterfly plates below the grate cut off the air supply from part of the grate area at times of light load. The accompanying table gives the principal results of three steam trials:

Test No.	I	II	III
Kg. fuel per m.^{2} of grate surface	149.7	199	222
Kg-cal. per hr. per m.^{2} grate	565,000	706,000	800,000
Draft in combustion chamber, mm. of water	2.5	2.7	5.2
Draft behind economizer, mm. of water	5.2	5.7	10.6
Percentage of Heat:	%	%	%
Utilized in boiler.	62.9	59.6	59.8
Utilized in superheater.. ..	5.3	6.1	7.5
Utilized in economizer..	11.8	10.5	11.9
Lost in flue gases....	13.2	12.4	15.0
Lost in ash (unconsumed), radiation, and conduction..	6.8	11.4	5.8

A noticeable point is the low draft required. The loss of draft amounts to 2.7, 3, and 5.4 mm. water column at heating-surface loads of 28.3, 33.3, and 38.1 kg. per m.^{2} respectively. During these tests the guaranteed maximum power was obtained without artificial draft. (Taken from *Science Abstracts*, Section B—*Electrical Engineering*, vol. 21, pt. 7, no. 247, July 31, 1918, p. 249, *d*)

Refrigeration

The Practical Side of the Low-Temperature Compression System, H. Sloan. Description of three different installations put into operation during 1917. All are operated in connection with brine-cooling systems. In addition to the description of the installation itself are given data of tests and some of the temperature readings especially analyzed.

The average suction pressure for the low-pressure cylinder was 0.935 lb. while the average temperature was — 11.85 deg. fahr.

This temperature agreed very closely with the outgoing brine temperature and did not follow temperature changes due to differences in the suction pressure, which means that the degree of superheat depends upon the temperature of the brine circulated.

The discharge temperature for the low-pressure cylinder averaged 123.3 deg. fahr. The gas entering the intermediate pressure drum (a long header into which the gas from the low-pressure ammonia cylinders is discharged and where it is cooled to the saturation point of the pressure corresponding to the intermediate pressure) was cooled to the average temperature of 15.19 deg. fahr., at which temperature it entered the high-pressure cylinder. The average pressure on the intermediate drum was 28.4 lb. and the temperature of saturated gas cor-

responding to this pressure is 15.5 deg. fahr., which indicates that the gas entered the high-pressure cylinder in a saturated condition and is important as an indication of the efficiency of the method employed for removing the superheat due to compression in the low-pressure cylinder.

If the low-temperature compression system secures the desired results, it will have the advantages of smaller dimensions in the cylinders on account of higher volumetric efficiency, and a reduction in ammonia losses due to combustion and cooling of the liquid ammonia at low-suction pressure with the intermediate pressure. (*A. S. R. E. Journal*, vol. 4, no. 6, May 1918, pp. 549-556, and discussion, pp. 556-560, 4 figs., *dt*)

Rolling Mills

THE SLICK WHEEL MILL. Description of a new process of making car wheels in which they are formed directly from large rolled bars by a rolling-forging process as now applied at the Cambria Steel Works.

The process begins with a cylindrical bar from 18 to 20 in. in diameter, rolled from a standard-size ingot. This bar is introduced into the rotary shear which cuts off short cylindrical blanks of the necessary size. The blanks are then transported to a heating furnace and heated gradually as necessary for the high-carbon steel used in making the wheels. From the furnace they go to a piercing machine which projects a short steel punch way into the center of the blank, making a cylindrical opening in the center thereof, and as this blank is introduced into the wheel mill a loose pin or mandrel which is previously placed in position is projected into the opening. As the wheel is pressed and rolled in the wheel mill this mandrel holds the blank centrally in position and at the same time forms a major portion of the length of the bore of the wheel or blank. The mandrel remains in the wheel or blank as it is rolled and is withdrawn from the mill.

The mill itself includes a pair of dies so arranged that the axis of one of the dies is at an angle to that of the other die. A hydraulic plunger of enormous size projects one die towards its companion die and an electric motor which can develop from 1000 to 2000 hp. is provided for rotating one of the annularly disposed dies, which by friction also rotates the companion die and the blank which is clamped between them and pressed by hydraulic pressure. The blank is shortened and assumes the reverse form of the dies as the pressure and rotation continue.

The time required to roll the blank into a wheel or other annular shape varies from 20 sec. for the smaller sizes with least work to about one minute for the large sizes with more work. A thrust of 3,000,000 lb. or more is taken up by large thrust bearings which are believed to be the largest in the world. These thrust bearings are shown in Fig. 15.

The rotary shear, Fig. 14, employs a pair of large disks arranged with their axes parallel, each disk composed of two pieces mounted on a large shaft and holding clamped between them by means of suitable bolts the shear blades proper. The round bar to be cut is carried on a longitudinal roller of large diameter which supports throughout its length and is adjustable to hold blank bars of different diameters in proper relative position to the shear knives. After one end (forming a blank) has been cut from the bar by the shear rotary knives, the bar is pushed lengthwise of the supporting roller between the side guides by means of a rotary pusher.

The shearing mechanism proper consists of two pairs of rotatable disks to which the eccentric shear knives are clamped.

In order to give a general idea of the large size of this machine, the following dimensions may be noted: The length of the shear proper is about 36 ft.; the length of the feed apparatus is about 60 ft.; and the length of the engine shaft or width of the engine is about 17 ft.; so that the whole apparatus is about 113 ft. long. The width of the shearing is about 18 ft. overall; the height is 13 ft. 8 in. above foundation and its weight approximately 850,000 lb.

The original article is illustrated by numerous line drawings and halftones showing the various details of the machinery

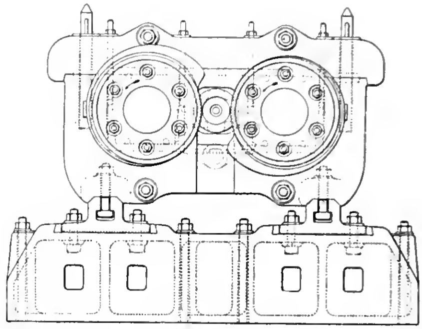

FIG. 14 SLICK ROTARY SHEAR

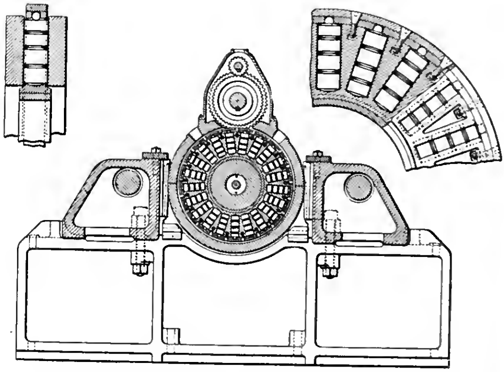

FIG. 15 ANNULAR THRUST BEARINGS USED IN THE SLICK WHEEL MILL

of the wheel mill and of its installation. (*The Iron Age*, vol. 102, no. 9, August 29, 1918, pp. 491-498. 17 figs., *dA*)

Steam Engineering

WRECK OF A 25,000-KW. TURBINE IN NEW WEST END STATION, CINCINNATI, OHIO. The accident to one of the two 25,000-kw. single-cylinder impulse turbines in Cincinnati occurred on September 4, 1918.

The turbine had been installed about two months previous and had satisfactorily passed the trial load tests. On the morning of September 3, i. e., the day before the accident, the machine was started at 8 o'clock and carried 12,000 kw. all day. At a little before 9.00 a.m. on the day of the accident the erecting crew had about 20,000 kw. on the turbine, which, at first, carried the load well. Then there was a loud bang inside the casing, followed by others accompanied by violent

vibration which shook the station. The throttle was immediately tripped, but the noise and vibration continued, much modified, until the machine slowed down to about 700 r.p.m.

From an inspection it appears that the seventeenth diaphragm was distorted at top and bottom. There are approximately 350 buckets in this diaphragm and all but eleven are burned or crushed.

The blades on this wheel are 28 in. long and made of steel; they have a shrouding over their tips, but use no rosary fastening. It is peculiar that about every tenth blade broke off immediately above where it was fastened on to the wheel, making a clean and sharp break. The blades which remained in the wheel were burned away at their top edges, the projections on the tips of the blades merely showing the effect of having the shrouding pulled away from them.

It is believed that the distortion of the diaphragm was the primary cause of the trouble, this being confirmed by the fact that the projections on the sixteenth diaphragm top and bottom show signs of rubbing on both halves.

It is interesting to note that the turbine was in operation five days after the accident, and, as a matter of fact, could have been put back in service even sooner, had it not been deliberately kept open for the inspection of the engineers of the builders. (*Power,* vol. 48, no. 12, September 17, 1918, pp. 425-426, 3 figs, *d*)

Wreck of the 35,000-Kw. Turbine in Northwest Station, Chicago. On Wednesday, August 1, the 35,000-kw. turbine in the Northwest Station of the Commonwealth Edison Company of Chicago was completely wrecked.

The present article gives the first published seemingly authentic information as to this accident and its probable cause.

The machine carried no load at the time of the accident, but had been in service all day. It was taken off the line shortly after midnight July 31, and the crew arranged to give the machine its regular monthly overspeed run to test the automatic-stop governor, and it was when this test was given that the accident occurred.

The article in *Power* correctly points out that if the stage had been set for observation of the machine, it could not have been better set. The accident actually happened during the test, under conditions ideal for observation of the machine and the taking and recording of the necessary measurements.

According to a statement of the switchboard operator, the speed at which the turbine began to be demolished was that which gave but 26½ cycles (the generator is of 25 cycles), which would mean a speed of 1590 r.p.m., or 6 per cent above the normal speed of 1500 r.p.m.

The steam pressure was 240 lb. and the throttle was wide open for the overspeed test, with the watch engineer standing at the throttle. Then came the thump, severe vibration and a crash as the low-pressure casing burst and pieces of metal flew about the room.

As regards the damage to the turbine the following facts, among others, are recorded as significant: The cast-iron low-pressure casing is blown away from the 18th wheel on. The diaphragms in the last low-pressure stages are broken up and the semi-steel cone supporting these diaphragms is demolished.

The next to the last (19th) low-pressure wheel has a large piece broken out, while the top of the periphery of the last or 20th low-pressure wheel is bent so that it presents a wavy line. The bedplate beneath the outboard-bearing pedestal is cracked.

The conclusion to which the writer comes is that it was the 19th wheel at the low-pressure end that was the first to let go. On the other hand, he does not believe it was the blades on the last two wheels that were torn off by centrifugal force alone.

In this connection, attention is called to an editorial in the same issue of *Power*, on page 355, devoted to the Chicago accident here described and a similar accident in Boston last February.

It is stated that experts who checked the design of the wrecked turbines gave it a factor of safety of four, so far as centrifugal stresses were concerned, but referred to the possibility of stresses being set up by unequal expansion through sudden changes of temperature.

It is significant that both of these accidents occurred immediately after changes in operating conditions, which involved a considerable temperature change in the low-pressure end—the first due to sudden imposition of an excessive load; the second to the taking off of the load. (*Power*, vol. 48, no. 10, September 3, 1918, pp. 345-348, 4 figs., *d*)

A New Theory of the Steam Turbine, Harold Medway Martin. This is a continuation of an abstract of a serial, the first installment of which appeared in The Journal, September 1918, p. 784.

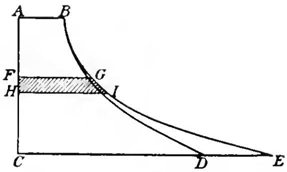

Fig. 16 Ideal Indicator Diagram for Steam Turbine

In the present installment the writer calls attention to the well-known fact that in steam-turbine practice the gain made by the use of superheated instead of saturated steam is substantially more than is thermodynamically due. This was shown quite conclusively by Baumann in a paper read before the Institution of Electrical Engineers (British) in 1912. Last year an extended set of correction tables drawn up by C. H. Naylor were issued under the auspices of the British Electrical and Allied Manufacturers' Association. From these figures, combined with the heat-drop tables issued by the same association, the present author secured the following figures of relative consumptions under certain standard conditions:

TABLE 1

Superheat, deg fahr....	0	50	100	150	200	250	300
Relative consumption.. ..	1.160	1.101	1.046	1.000	0.9592	0.9235	0.8909

From these figures and other data it would seem that the saving due to a superheat of 150 deg. fahr. is reckoned at 16 per cent instead of at 15 per cent as in Baumann's paper in 1912. This may be due to the improvement effected during recent years in average turbine efficiency, since, as the writer claims, with any given type of turbine the relative gain from using superheat should increase somewhat with the efficiency of the turbine. This is the reverse of the opinion generally held.

From this the writer proceeds to the consideration of the discrepancies between the gains and losses. To do this he takes for purposes of comparison the condition of the steam, not as supplied to the stop valve but after passing through the

governor valve. In addition, the discrepancies are made larger by the fact that the ratio of blade speed to steam speed is, on the average, less the greater the amount of available heat. Furthermore, the heat which becomes available in a steam turbine differs from the adiabatic heat drop and is, in general, considerably larger. The ratio of the two, known as the reheat factor, forms the subject of an important discussion by the writer, who claims that it is substantially greater for superheated than for saturated steam when the latter is assumed to be in thermal equilibrium throughout the whole of its expansion.

Suppose a turbine to consist of an infinite number of stages. At each stage a certain portion of the total energy of the steam is converted into kinetic energy, of which a part is expended in doing useful work on the shaft, and the remainder, which is wasted in friction, is restored to the expanding steam in the form of heat; the consequence is that at each stage the pressure corresponding to a given volume of the steam is somewhat greater than it would be did the turbine work friction-free. Whether steam be used to actuate a turbine or a reciprocating engine the amount of work done down to any stage of the expansion can be represented by an ideal indicator diagram such as is shown in Fig. 16. In this the expansion line BD is that corresponding to frictionless working or to unit efficiency, while BE represents the expansion line for a turbine working with an hydraulic efficiency η. The total area of the diagram is in this case larger than before, because the energy wasted in friction, being returned to the steam as heat, makes the volume at every point of the stroke more than if unit efficiency were attained. On this larger diagram, however, only the fraction η is recovered as useful work on the shaft, whereas in the ideal case of unit efficiency the useful work done is represented by the whole of the area $ABDC$. In all cases $\eta \times ABEC$ is less than $ABDC$.

The efficiency ratio ε of the turbine is equal to the actual work done divided by that theoretically due from a perfect turbine, or

$$\varepsilon = \eta\frac{ABEC}{ABDC}$$

and the reheat factor R is defined by the relation

$$R = \frac{ABEC}{ABDC}$$

so that $\varepsilon = \eta R$, where η is known as the hydraulic efficiency of the turbine.

The actual thermodynamic head under which any turbine works is therefore not represented by the adiabatic heat drop u, but by a larger quantity U, where $U = Ru$.

From this the writer proceeds to show how to determine the value of the reheat factor corresponding to different values of the hydraulic efficiency of the turbine and comes to the expression

$$R = \frac{1}{\eta} \cdot \frac{1-\left(\frac{1}{x}\right)^{\eta[1-(1/\gamma)]}}{1-\left(\frac{1}{x}\right)^{[1-(1/\gamma)]}}$$

where η is the hydraulic efficiency of the turbine and x the ratio of the initial to the final pressure. From this he derives the values of the reheat factor for superheated steam throughout the whole range of its expansion for the various hydraulic efficiencies given in Table 2.

In other words, the efficiency ratio of a turbine is defined as the product of its hydraulic efficiency and the reheat factor.

In view of its use elsewhere in this discussion attention is called to the following expression for λ:

$$\lambda = \frac{1+\frac{1}{\gamma-1}}{\frac{1}{\gamma-1}+k}$$

where γ is the index when the expansion is adiabatic.

Among other things the writer calls attention to the paradox following from the above expression for the reheat factor R. If the expansion be carried far enough, the efficiency ratio is independent of the hydraulic efficiency which can be shown by making $x = \infty$. Since then the efficiency ratio is equal to $R\eta$, its value is always unity if the expansion be carried to zero pressure. The following physical explanation is given: To reduce the final pressure to zero we must go down to the absolute zero of temperature. In deducing the value of R it was assumed that all the heat energy not expended in doing useful work was restored to the fluid in the form of heat. At the absolute zero of temperature the working fluid retains no heat energy and the latter has accordingly all been turned into useful work and the efficiency ratio is unity, however great the frictional losses may have been at each stage of the turbine.

The writer points out that the error in reheat factors for wet or saturated steam is considerable, because for the adiabatic expansion of such steam in thermal equilibrium the expression of the form pV^n = constant (where $n = \gamma$), is only moderately

TABLE 2 REHEAT FACTOR FOR STEAM SUPERHEATED THROUGHOUT THE WHOLE RANGE OF ITS EXPANSION

Values of $x = \frac{p_0}{p_1}$	Hydraulic Efficiency η			
	0.5	0.6	0.7	0.8
1	1.0000	1.0000	1.0000	1.0000

20	1	1.0496	1.0394	1.0294	1.0191	1.0088
25	1	1.0537	1.0427	1.0318	1.0210	1.0104
50	1	1 0669	1.0531	1.0394	1.0261	1.0129
100	1	1.0809	1.0640	1.0475	1 0313	1.0155
200	1	1.0956	1.0755	1.0559	1.0368	1.0162

accurate. In such a case the reheat factor may be determined in another way, published in *Engineering* several years ago. The writer repeats the argument presented there and gives a table showing the value of reheat factor for steam unusually dry and expanding in thermal equilibrium throughout, that is to say, with no undercooling, a condition which is, however, not realized either in a steam turbine or in a reciprocating engine. These values are given in Table 3.

The writer makes the following comparison of Tables 2 and 3. Suppose a steam turbine designed to give an hydraulic efficiency of 0.7 for the range of expansion of from 200 lb. absolute down to 1 lb. absolute. Then if the steam supply is saturated and the expansion takes place in thermal equilibrium throughout, its thermodynamic efficiency ratio will, from Table 3, be $0.7 \times 1.0559 = 0.739$ nearly. If, on the other hand, the turbine is designed to give the same hydraulic efficiency with steam supplied at 200 lb., and superheated to such an extent that the superheat is not lost when the exhaust port is reached, the efficiency ratio will be $0.7 \times 1.1643 = 0.815$ nearly. Hence, with the same hydraulic efficiency the thermodynamic efficiency ratio will be fully 10 per cent more with superheated than with saturated steam expanding in thermal equilibrium.

It will be obvious, therefore, that the adiabatic heat drop forms a somewhat fallacious foundation for estimating the saving to be effected by superheating the steam. (*Engineering*, vol. 106, no. 2742, July 19, 1918, pp. 53-55, 3 figs. The article is to be continued, *tA*)

The 45,000-Kw. Compound Turbine at Providence, R. I., J. P. Rigsby. Description of a turbo-generator unit recently put in operation at a local power plant in Providence, R. I. It is of the Westinghouse cross-compound, double-unit type, the high- and low-pressure sides each driving a generator of 22,500 kw. capacity. These generators are mounted on separate bedplates supported on foundations parallel to each other.

The energy given up by the steam at full load is equally divided between the high- and the low-pressure turbines, though at lower loads a greater proportion is carried by the high-pressure element. The steam pressure at the throttle is set at 200 lb. with 100 deg. fahr. superheat and a vacuum of 29 in. in the exhaust. At the high-pressure element the speed is 1800 r.p.m. and at the low-pressure element 1200 r.p.m.

Several features of construction of the turbine are of particular interest. Thus, the high-pressure spindle consists of a hollow steel drum about 3 ft. in diameter carrying most of the blading. There are two blade rings of larger diameter at the one end and corresponding dummy rings or balance pistons on the other. The spindle ends are pressed into the drum and are secured with T-headed shrink links, which are themselves held in place by the blade and dummy rings.

The low-pressure spindle consists of a central hollow drum rigidly secured to the spindle ends with two disks mounted upon each of these ends. These disks carry the low-pressure blades, the maximum mean velocity of which is so low that ordinary good cast steel can be used in the blade rings.

The condenser equipment is claimed to be the largest in the world. The condenser unit is composed of two separate and distinct low-level jet condensers, which can be operated together or separately, if necessary. The same water level is maintained in each condenser by the use of a water-equalizing connection between the two pump bodies. This water-equalizing connection is so constructed that no surges occur between the condensers. For this purpose a connection is made in the form of a tee, the bottom of which forms a reservoir, and a baffle running almost to the bottom prevents surging; also an air-equalizing connection is provided to maintain the same vacuum in each condenser. (*Power*, vol. 48, no. 9, August 27, 1918, pp. 292-298, 9 figs., *dA*)

Varia

Einstein's Gravitation Theory, I, II, III and IV, H. A. Lorentz (*K. Akad. Amsterdam*, Prov. 19, pp. 1341-1369, and 20, pp. 2-34, 1917). The author considers that through the Einstein equations the general theory of relativity may now be regarded as having assumed a definite form. He attempts, in the present communication, to prepare the way for its future development and application to special problems: (1) by presenting the fundamental ideas in as simple a form as possible, (2) by showing how Einstein's differential equations for the gravitation field can be derived from Hamilton's principle, and, in connection therewith, dealing with the energy, stresses, momenta, and energy currents in that field. By means of a four-dimensional geometric representation it is shown that any system consisting of material points and an electromagnetic field is expressible in terms of a single quantity H occurring in the variation theorem, and which is called the *principal* function. It consists of three parts, referring respectively to the material system, the electromagnetic field and the gravitation field, the material points being assumed to have no connection other than that resulting from their gravitational attraction. Space and time are combined in the four-dimensional extension R_4, a point P in which indicates a definite place at a definite instant. The curve traced out by P when the time coördinate only varies is called, after Minkowski, a *world line*, so that an intersection of two world lines represents the coincidence, at a certain moment, of the two objects to which they belong. It should be noted that a propagated light wave will have its world line. And Einstein observes that our observations can determine only these coincidences, so that if astronomical data could be extended arbitrarily and without limit, a gravitation field, e.g., that of the sun, with its material points and light waves, would be completely defined by a field figure consisting of the world lines in R_4, drawn so that each observed coincidence is represented by an intersection of two lines, and so that the points of intersection succeed each other in the right order. It should therefore be possible to express the fundamental laws of physical phenomena by geometric considerations referring to the field figure in such manner that this mode of expression shall be the same for all possible field figures. The introduction of coördinates is of secondary importance in a geometrical treatment of this kind, and employed by the author only to obtain the equation representing the connection between the electric and magnetic forces, on the one hand, and the charge and convection current, on the other; and to establish the general equations, which are required for the solution of special problems. Since coördinates play no essential part in the general discussion of principles, the latter must necessarily be independent of the actual coördinates chosen, so that the general covariancy of the equations postulated by Einstein is assured beforehand. (Taken from *Science Abstracts*, Section A—Physics, vol. 21, pt. 7, no. 247, July 31, 1918, pp. 282-283, *g*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THREE MILLION men at the front by July 1, 1919, is more easily attainable than the industrial readjustment by that time to maintain three million men. The most important task before the country is that of industrial readjustment, the work peculiarly that of the engineer.

On the occasion of a recent visit to Washington with regard to the essential curtailment of the paper used in the Society's publications, the Secretary had an opportunity to take up with Mr. C. A. Otis, Chairman of the Resources and Conversion Division of the War Industries Board, the work of the Society's Committee on War Industries Readjustment, and was pleased to learn that this was eminently satisfactory. In fact, Mr. Otis warmly complimented the Society for its enterprise. The task is stupendous, however. It is more than the Administration in Washington, no matter how powerful or well organized, can complete alone. It must be done by individuals throughout the United States. Hence this appeal through our members and to all they can influence, to undertake only such activities as have a direct effect on winning the war.

Through our Local Sections, corresponding to the Regional Committees of the War Industries Board, any member may secure information, either as to what are the prospective requirements of our Government on the one hand, or to place before the proper authorities the information respecting the abilities of any plant to undertake work. In other words, our Society, through its several committees, is able to act as one of the clearing houses of the Government in this essential work of readjustment.

Another essential work of the people of the United States is that of invention, and here again the Society is prepared to act as a clearing house to ascertain on the one hand the problems to be solved and on the other hand to offer the special abilities of individuals who are prepared to give all or a portion of their time either at places designated by the Government or at their offices or homes.

In connection with these very essential activities of the Society, you will note in the program of the coming Conference at Indianapolis that we are to have the subject of research treated authoritatively by the head of the Mechanical Engineering Division of the National Research Council, Prof. W. J. Lester. Professor Lester is a very forceful and fluent speaker.

The above are the immediately obvious requirements of the hour which every member will naturally wish to undertake. The more far-reaching and fundamental activities of the Society, however, are those of setting and maintaining the ideals of the engineering profession. In connection with the Indianapolis Conference on October 25-26, an opportunity is to be afforded representatives from each of the Sections in the United States to bring together the point of view of the membership on the great questions of engineering ideals; and we are to have a "self-examination," as some friend has called it. It is hoped that in the following month the Local Sections all over the United States will further discuss this matter by calling on their respective representatives to report the results of the Indianapolis Conference. Then at the Annual Meeting in December there will be a still more representative gathering of engineers from all over the United States for a further discussion and statement of the objects and aims of a professional engineering society. All those members who cannot attend the Indianapolis meeting are urged to write their views, and failing also to attend and speak at the Annual Meeting in New York, they should write to the Secretary.

During the war, views of the world and the members of the engineering profession have undergone a change and it behooves the Society, as expressing the thoughts and ideals of the profession, to lead in that expression.

CALVIN W. RICE,
Secretary.

The Coming Annual Meeting

Plans for the Annual Meeting, to be held December 3-6, have so far developed that tentative announcement of several of the sessions can now be made. The practice in previous years of having a leading subject for the meeting of broad, general interest, will be adhered to, with a discussion throughout the day on Wednesday, December 4, of the general topic on Human Engineering, particularly in reference to questions of administration which have arisen in the war industries. The titles of the papers now in preparation for this session are as follows: Organization; Standardization and Administration of Wages; Non-Financial Incentives; Incentive of Control in Industry; Employment of Labor; Dilution of Labor; Intensive Training; Human Relations in Industry.

There will be at least two sessions for general papers of technical interest for which an ample variety of strong contributions have been received.

One session will be under the auspices of the Gas Power Sub-Committee with papers on oil engines and cooling losses in combustion engines. Another session will be in charge of the Sub-Committee on Textiles, with papers on industrial power problems and aeroplane fabrics. A session arranged by the Sub-Committee on Machine Shop Practice will be devoted to the subject of gages, methods of manufacture and testing. The apparatus in the Department of the Bureau of Standards, located in the Engineering Societies Building, New York, will be added to with a view to placing the equipment on exhibition during the meeting.

Another session will be a joint session with the American Society of Refrigerating Engineers, which holds its annual convention simultaneously with that of our own Society. Papers will be contributed by both societies.

Everything points to a most successful meeting, equal if not exceeding those of the last two years which have been the largest in the history of the Society. On Wednesday and Thursday evening of the meeting there are to be addresses or moving pictures relating to the war, and the trend of many of the papers at the special sessions will be in the direction of the work which the members of the Society and other engineers are accomplishing in the one all-absorbing undertaking of the present time. It is expected that complete details will be given in THE JOURNAL for November, together with abstracts of the papers.

Women's Auxiliary of the A. S. M. E.

The organization meeting of the Women's Auxiliary of the A.S.M.E. was held at Society headquarters on September 20, at the call of Mrs. Charles E. Davis, whom President Main had appointed as representing this Society at the invitation of the Council of Organizations for War Service. The families of all local members were invited, and formed an enthusiastic gathering. The meeting was addressed by Miss Esther Lape, Secretary to the Section on Aliens of the Council of Organizations for War Service, who told the ladies of the work to be done in the War Information Centers of the city.

It was voted to organize under the following officers: Mrs. Charles E. Davis, Chairman; Mrs. E. J. Prindle, Vice Chairman, and Mrs. Jesse M. Smith, Secretary.

The Committee plans to circularize the ladies shortly for volunteer service along these lines.

Commission to Standardize Screw Threads

The Act recently passed by Congress for the appointment of the Commission to Standardize Screw Threads is now a law and is being carried out, and it is expected that within a few days Secretary Redfield will have officially announced the names of the members of the Commission.

An informal organization meeting was held recently in Washington in which extensive preparations were made for carrying out this important standardization work. Manufacturers of every kind of screw thread, no matter for what purpose, whether they be screws for use on battleships, in rolling mills, machine tools, looms or surgical instruments, typewriters, etc., will be requested to furnish the Commission, whose headquarters will be at the Bureau of Standards, Washington, with complete information as to the type of thread they are using. It is particularly desired that they list each size manufactured, stating the pitches, system and form of thread, the tolerances, nomenclature, the gages in use and the methods of testing and gaging.

This information will be carefully collated by the Secretary to the Commission, and all manufacturers and others interested will be invited to appear before the Commission in order that their particular form of product may have proper consideration.

The Commission is arranging a series of meetings in Washington, D. C., and in other parts of the country, at which all manufacturers will have an opportunity for a hearing.

A questionnaire is to be sent out at once, and manufacturers who for any reason fail to receive a copy should apply immediately, addressing the Secretary of the Screw Thread Commission, Bureau of Standards, Washington, D. C

New Volume of Transactions

Volume 39 of Transactions is now being issued to the membership. It contains an account of the activities of the Society for 1917, the year in which the United States entered the great war. The volume includes the papers and addresses given at the Spring and Annual Meetings and a selection of papers presented at meetings of the Local Sections. Inevitably many of these relate to problems with which engineers are concerned in the prosecution of the war and to which, with patriotic devotion, they are giving their undivided thought and attention.

At the beginning of the war this Society, in common with many others, tendered its services to the President of the United States. The offer was promptly accepted to the great satisfaction of the membership, and as the needs of the Government have grown the Society has responded to the many requests which have come to it.

Individually, also, the members have heeded the call and are serving in almost every department of the Government, abroad at the front, at the Nation's Capital, in arsenals, navy yards, shipyards, aviation fields, etc., and in the industries of the country engaged in munitions manufacture. The earnest and helpful spirit resulting from these many points of contact is reflected in the pages of this volume.

Eighth Volume of Condensed Catalogues

The eighth annual volume of the A. S. M. E. Condensed Catalogues is now coming from the press and it is with much pleasure that the Society records a further considerable gain in size and comprehensiveness of this useful volume.

Four hundred and fifteen firms, including a majority of the leading manufacturers in their respective lines, are represented by publication of catalogue data. The General Mechanical Equipment Directory, in which all eligible manufacturers are entitled to listing of their products free of charge within reasonable limits and irrespective of the use of space, has also been extended and improved and it is believed that this reference feature will prove of even greater value than heretofore. The Engineering Data Section contains, in addition to the usual material, a complete list of Transactions papers beginning with the first volume issued in 1880.

U. S. Navy Needs Steam Engineers

The urgent demand for engineers to man the supply and cargo ships of the U. S. Navy has forced the Navy Department to redouble its efforts for obtaining men adapted for this service. It is fully realized that there are many men at the present time who are anxious to join the service, but do not know where they fit in. The U. S. Navy Steam Engineering School at Hoboken, N. J., is giving a five-months' course in steam engineering to those men who are able to qualify. It has been found that those men who have either a mechanical or electrical engineering degree or have pursued these courses, and have not graduated, but have had sufficient practical training, constitute excellent material. Many men who are not technical graduates, but have had practical experience covering a number of years have also qualified.

Through arrangement with the War Department the Navy will be permitted to induct, individually, through its local board, a given quota of men, who have special qualifications. Application for this school should be sent to Ensign C. L. McIntyre, 225 West 42nd St., New York City.

Committee on Aims and Development

The Council, at its meeting on September 20, authorized a Committee on Aims and Organization to discuss and formulate aims of the Society in the light of modern development and present-day thought, and to assist toward finding a method of coöperation with the rest of the engineering profession suitable to carry out these aims. The Committee is being appointed by the President, and consists of one delegate from each of the Local Sections, and a number of members-at-large selected by the President. It is planned to hold a general meeting of the Committee in Indianapolis, October 24-26, coincidentally with the meeting of the Council and of the Mid-Western Sections in that city, and the President will appoint an Executive Committee from the general committee to lay out the program of work.

CHAIRMEN OF STANDING COMMITTEES OF ADMINISTRATION NOW MEMBERS OF THE COUNCIL

In accordance with the amendment to C 15 of the Constitution, which became effective at the last Spring Meeting, the Standing Committees of Administration now consist of the following: Finance, Meetings and Program, Publications and Papers, Membership, Local Sections and Constitution and By-Laws. The appointment, organization, duties and terms of service of these committees are to be designated by the By-Laws.

An important feature of the amendment is that the chairman of each of the Standing Committees of Administration shall have a seat in the Council of the Society, although they have no vote. At the Council meeting held last month, these chairmen were, for the first time, privileged to take part in the proceedings in their new capacity as committee representatives.

This is an important step in the Society's development. It assures that those who are directing its fundamental activities will meet together once a month with the other members of the Council and there present for consideration the important interests which they represent. It will undoubtedly facilitate the prompt transaction of business and enhance the coördination of effort which is so essential in a large organization.

In view of the initiation of this forward step at the present time, we are pleased to publish in this number of The Journal the portraits of the several chairmen. Four of these chairmen become new members of the Council, one of these, however, Mr. Jesse M. Smith, Past-President of the Society, having previously had long service as a Council member. The other two committee chairmen, Mr. R. M. Dixon of the Finance Committee, and Mr. D. Robert Yarnall of the Sections Committee, were already Council members.

Coöperation Between the A.S.M.E. and the War Industries Board

One of the important recent activities of the Society has been the work of its War Industries Readjustment Committee and its Regional Representatives in aiding manufacturers throughout the country in the adaptation of their plants to the production of war material, as outlined in The Journal for August 1918, page 695.

This matter originally came up at a meeting of the New York Local Section on non-essential industries held last February, after which a committee was appointed to investigate and report. This led to the appointment of a permanent committee in June, consisting of G. K. Parsons, *Chairman*, Erik V. Oberg and Fred A. Scheffler.

Later, this work was taken up on a broad scale by the War Industries Board of the U. S. Government, through its Resources and Conversion Section, of which Mr. Charles A. Otis is chief. A War Resources Committee and a Regional Advisor were appointed by the Government in each of 20 sections, or regions, of the United States for the purpose of organizing the various lines of trade in the different regions.

As soon as this plan was announced, our President, Mr. Charles T. Main, immediately appointed a Regional Representative of the Society in each of these 20 regions to coöperate with the War Resources Committees and the Regional Advisors of the Government.

In this connection it will be of interest to describe what has been done by our War Industries Readjustment Committee, the chairman of which, Mr. G. K. Parsons, is Regional Representative in Region No. 3 (New York), in coöperation with the local Regional Advisor of the Government in this region, Mr. William F. Morgan. This committee of the Society has been called upon to make a number of industrial surveys for Mr. Morgan for a number of different purposes, such as:

1 To determine the wisdom of the Government's letting contracts for certain munitions to particular manufacturers.

2 To determine whether the essentiality of the products of a certain corporation, together with its probable future requirements, were sufficient reason to warrant permitting it to increase its capital stock.

3 To determine the fitness of certain plants for the manufacture of products which had never been manufactured there before, and the ability of the prospective management to establish the essential industry in question.

4 A study of various industries to determine what sort of essential work they can best be adapted to.

The foregoing illustrates, not only to our regional representatives, but to others, how our members can best render assistance in this work. A plant which can take on war work, as well as those plants which are overburdened with war work and would like the assistance of some other plant on part of its work, should notify either the Regional Advisor of the Government, or the Regional Representative of the Society, whose headquarters are nearest at hand.

When a manufacturer notifies the Regional Advisor of the War Industries Board that he is in a position to accept orders for war work he should be prepared to state specifically just what class of articles he can manufacture and the rate of production. Also in certain instances it will be advisable for the manufacturer to state the number and class of help employed, the number, size and type of machines which the plant contains.

Following is a list of the Regional Advisors of the War Industries Board and of our Regional Representatives:

Regional Representatives

War Industries Readjustment Committee

Boston, A. C. Ashton, 33 Columbus Ave., Somerville, Mass.
Bridgeport, Harry E. Harris, Post Office Box 852.
New York City, G. K. Parsons, 29 Pine St.
Philadelphia, C. N. Lauer, Day & Zimmermann.
Pittsburgh, J. M. Graves, 435 Sixth Ave.
Rochester, Ivar Lundgaard, 208 Culver Rd.
Cleveland, F. H. Vose, 3203 Whitehorne Rd., Euclid Heights.
Detroit, E. J. Burdick, 511 Seminole Ave.
Chicago, A. D. Bailey, 21 Elmwood Ave., LaGrange, Ill.
Cincinnati, Fred A. Geier, 2301 Grandview Ave., E. W. H.
Baltimore, Wm. W. Varney, 710 North Carey St.
Atlanta, Robert Gregg, 960 Ponce de Leon.
Birmingham, W. P. Caine, Tenn. Coal, Iron & R. R. Co., Ensley, Ala.
Kansas City, J. L. Harrington, Rockhill Manor.
St. Louis, R. L. Radcliffe, 701 Laclede Gas Bldg.
Milwaukee, W. M. White, 747 Summit Ave.
San Francisco, B. F. Raber, 2027 Delaware St., Berkeley, Cal.
Dallas, A. C. Scott, Scott Engineering Co.
Seattle, R. M. Dyer, Puget Sound Bridge & Dredging Co.
St. Paul, Oliver Crosby, 63 S. Robert St.

Regional Advisors

War Industries Board

Boston, Stuart W. Webb, Chamber of Commerce.
Bridgeport, B. D. Pierce, Jr., 1st Bridgeport Nat'l. Bank Bldg.
New York, Wm. F. Morgan, Merchants Assn. of New York.
Philadelphia, Ernest T. Trigg, 1228 Widener Bldg.
Pittsburgh, Geo. S. Oliver, Chamber of Commerce.
Rochester, E. A. Fletcher, Chamber of Commerce.
Cleveland, W. B. McAllister, Chamber of Commerce.
Detroit, Allan A. Templeton, Detroit Board of Commerce.
Chicago, D. E. Felt, 29 S. LaSalle St.
Cincinnati, Edwin C. Gibbs, 31 E. 4th St.
Baltimore, S. F. Shavannes, Merchants & Mfrs. Assn.
Atlanta, Edw. H. Inman, Chamber of Commerce.
Birmingham, T. H. Aldrich, 322 Brown-Marx Bldg.
Kansas City, Franklin D. Crabbs, 10th & Central Sts.
St. Louis, Jackson Johnson, 510 Locust St.
St. Paul, D. R. Cotton, 1414 Pioneer Bldg.
Milwaukee, August H. Vogel, 4th Floor, City Hall.
Dallas, Louis Lipsitz, 407-9 Southland Life Bldg.
San Francisco, Frederick J. Koster, Chamber of Commerce.
Seattle, Herbert Witherspoon, Chamber of Commerce.

Resolutions by Committee on Public Relations

The following resolutions of the Public Relations Committee of the Society, Dr. F. H. Newell, *Chairman*, constitute a progress report of the committee and offer a constructive statement regarding the status of the engineer in public affairs—his obligations to the public and his opportunity for leadership:

1 The object of this Committee is to give special attention to those matters not specifically covered by the work of other Committees and which have to do with the larger relations of the Society and of its members to the public.

2 Because these relations have not been kept continuously prominent nor widely emphasized, there has been more or less misapprehension on the part of the public as to the work of the Society and of its members, especially in larger affairs of general concern. It is obviously the duty of this Committee to do what it can to improve this understanding.

3 In the rapid evolution of affairs, the engineer as a man and citizen, in order to hold his proper position relative to other professions and callings and to do his part, must be continually alert in keeping the public aware of the fact that the great work of war and of peace is that of the engineer and that in this he should be a leader. In order to fully employ his ability he must enjoy a proper appreciation and be free from the limitations which may be imposed by others who do not possess a wide view of engineering achievements and possibilities.

4 While it is realized that there must be radical changes in the education of the engineer to enable him in the future to fill the requirements of larger leadership, yet at the present time much can be accomplished by the present organizations devoting time and energy to progress in other than purely technical lines. The engineering society to meet present conditions should seek advance in those matters which aid the engineer in being more effective, outside as well as inside his purely technical occupations.

5 In seeking such advance it is practical to learn from other associations of educated men holding similar high ideals and which

have worked out practical methods for achieving result such for example as the Architects, the Commercial Clubs, the Doctors and Lawyers.

6 There is need of a well-considered scientific study of the ways which have been found advantageous by such organizations and a comparison of their methods and conditions with those of the mechanical engineer.

7 Growing out of such study should be the development of a carefully considered plan designed to put the engineer in the best possible relation with the public, not directly for private gain or gratification, but in order that each man may perform his largest functions for the benefit of society and that he may fulfill more completely the duties which come to him because of the fact that he has been educated partly at public expense and as an educated man has superior obligations to the world about him.

8 Following such study should be an awakening of the membership to the fact that the engineer as a man can and should occupy a position of wider initiative and leadership in public affairs. This can best be done by a carefully-thought-out series of papers on the subject.

9 At the same time the public should be educated to an appreciation of the fact that the engineer can and should perform still larger functions with corresponding benefit in increased comfort, health and prosperity of the community.

10 Organized effort should be made to anticipate action by officials in appointments to places of responsibility which because of the nature of the work should be filled by engineers. It should be made difficult, if not impossible, for the position of director or superintendent of public works and construction to be filled by other than men having an engineering education and experience.

11 There should be facilities provided for exchange of ideals and experience among engineers in the public employ, giving them the information and moral support in their efforts for higher public service.

12 While any betterment in the status of the engineer in the long run will redound to the benefit of the public, the profession should constantly be reminded that its position in the community will be conditioned largely by what it does for the public. In striving toward any widening of influence in American life our dependence must be on actual service rather than on any demand for recognition, no matter how logical.

ALL SHOULD COME TO INDIANAPOLIS

October 25 and 26

By the time this issue of The Journal is in the hands of the members the final program of the big joint meeting of the Mid-Western Sections, to be held in Indianapolis on October 25 and 26, in connection with the Council meeting there, will have been completed. As now determined, the event at Indianapolis comprises the Council meeting on Friday morning, the joint meeting of the Indianapolis, Cincinnati, St. Louis, Chicago, Milwaukee, Detroit, and, it is hoped, Cleveland Sections, together with a meeting of the new Committee on Development of the Society, and a meeting of the Fuel Conservation Committee of the Engineering Council. The Indiana Engineering Society, the Indianapolis-Lafayette section of the American Institute of Electrical Engineers and the Indianapolis section of the Society of Automotive Engineers have also been invited to participate.

The Indianapolis Committee is in charge of the arrangements. This committee comprises:

Lawrence W. Wallace, Chairman, Asst. General Manager, Diamond Chain & Mfg. Co.

W. A. Hanley, Vice-Chairman, Chief Engineer, Eli Lilly & Co.

B. G. Mering, Treasurer, Industrial Engineer, American National Bank Bldg.

Charles Brossman, *Secretary*, Consulting Engineer, 1616 Masons' Bank Building.

Gilbert A. Young, head of M. E. Department, Purdue University, Lafayette, Ind.

F. C. Wagner, Professor Mechanical and Electrical Engineering, Rose Polytechnic Institute, Terre Haute, Ind.

The Local Committee will be glad to furnish any one information on transportation to Indianapolis, and will secure hotel accommodations, arrange to meet visitors at the trains upon notification, etc.

Headquarters

The headquarters of the meeting will be the Claypool Hotel, where also the two professional sessions scheduled and the committee meetings will be held. While the hotel has ample accommodations for a large number of guests, and while no overcrowding is anticipated at this season of the year, members intending to go to Indianapolis should get in touch with the Local Committee and ask them to secure reservations for them in advance. The Local Committee intends to immediately issue to all members information on the cost of accommodations, on transportation, and also a copy of the final program.

Program

As determined at the time of going to press with The Journal, the program is as follows:

Friday, October 25

9:30 a. m. Registration at Claypool Hotel.

9:30 a. m. Meeting of the Council.

11:30 a. m. Meeting of the Committee on Local Sections and members of the Executive Committees of the Mid-Western sections.

12:30 p. m. Informal luncheon at the Claypool. The Mayor of Indianapolis is confidently expected to welcome the visitors and President Main to respond.

2:00 p. m. Symposium on Fuel Conservation:

An Explanation of the Regulations of the Fuel Administration, by Dr. P. B. Noyes, Director of Coal Conservation, U. S. Fuel Administration.

What the Fuel Administration Expects of the Engineers, by David Moffat Myers, Advisory Engineer, U. S. Fuel Administration.

Discussion, in which the Administrative Engineers of the Fuel Administration and members of the Society will participate.

6:30 p. m. Informal dinner, at which nominee for President M. E. Cooley, is expected to speak, followed by war pictures.

Saturday, October 26

9:00 a. m. Symposium on Research.

Opening address by Professor Walter Rautenstrauch, member of the Society's Committee on Research.

Address by Dr. W. J. Lester, Vice-Chairman of the Mechanical Engineering Division of the National Research Council.

Discussion by members of the Society.

11:30 a. m. Exhibition of the Liberty Motor.

12:30 a. m. Informal luncheon at place arranged by the Local Committee. Members and guests will be conducted in automobiles.

The afternoon will be free for excursions, and the local committee is making arrangements to be announced.

The Local Committee hopes to arrange for members to visit both the Columbia Club, the features and functions of which are so unique as to call attention to it all over the country, and the Canoe Club, which has a large membership of professional and business men, and a splendidly equipped building.

Committee Meetings

Committee meetings other than the ones listed on this program include a meeting of the new Committee on Development, which is a committee appointed by the President and confirmed by the Council to inquire into the aims and activities of the Society in a similar manner to the committees of the Civil Engineers and the Mining Engineers. This committee consists of delegates from each of the Local Sections and members at large appointed by the President, and it is expected that the entire committee will be present at the Indianapolis meeting. The meeting of this Committee will, it is hoped, commence on Thursday afternoon and continue throughout the whole time at Indianapolis.

The Fuel Conservation Committee of the Engineering Council, which is connected with the Bureau of Mines and with the Fuel Administrator and is studying and devising problems of fuel utilization, especially coal, will meet at a time and place to be determined.

Let Every Nearby Member Attend

The Committee on Local Sections and the Local Committee of the Indianapolis Section assure all members who go to this meeting and who bring their friends, a profitable and enjoyable time. Special arrangements will be made to take care of visiting ladies and no pains will be spared to make this meeting, which is the first of a series of joint meetings planned by the Sections Committee, an occasion of benefit. The period of the meeting is planned so that members who attend will be inconvenienced in their work as little as possible. They will be able to get in four days' work in the week and spend the week-end in Indianapolis.

Indianapolis is the largest inland city on the American continent and one of the most important railroad centers in the country. It is also one of the handsomest cities and one of the most prosperous and progressive. Its growth has been practically that of two decades. It is the commercial, social, educational, political and governmental center of Indiana and is more typically the capital of a state than any other like city in the country. It is situated 60 miles from the center of population of the United States, and is within the geographical center of manufacturing. The city has more than 1200 factories; in the output of automobiles it is the second city in the country.

AMONG THE SECTIONS

Cleveland Section

At the September meeting of the Council the petition of the members of the Society residing in Cleveland for a Local Section in that vicinity, duly passed by the Committee on Local Sections, was approved. This new Section comprises the towns or cities of Akron, Barberton, Bedford, Chardon, Cleveland, Cuyahoga Falls, East Cleveland, Elyria, Hudson, Kent, Lakewood, Lorain, Massillon, Quarryville, Ravenna, Sandusky, South Euclid, Wickliffe, Willoughby, and Wooster, totaling a Society membership of approximately two hundred and sixty at the present time, the sixth largest in the country.

The new Section comes into being as the mechanical-engineering section of the Cleveland Engineering Society, organized in 1891 and now comprising a membership of approximately a thousand, and known throughout the country as one of the most active and influential local organizations of engineers. The national societies of Civil Engineers, Electrical Engineers and Automotive Engineers all have organized groups in Cleveland, so that opportunities for coöperation and coördination of activities are manifold.

Many of the officers and prominent members of the Cleveland Engineering Society are also included in our own membership, notably R. I. Clegg, Prof. F. H. Vose, Col. E. H. Whitlock, F. L. Sessions, F. W. Ballard, A. H. Bates, H. C. Hale, A. G. McKee, and J. H. Stratton. In addition to the liaison members, there are C. E. Drayer, George S. Black and W. O. Henderer of the C. E. S.; and Ambrose Swasey, Worcester R. Warner, S. T. Wellman (past officers of the Society), G. E. Merryweather and R. H. Danforth. Upon the abilities of these gentlemen we may count to realize to the fullest extent the enthusiasm in coöperative service for the greatest good.

It is hoped that papers presented at the proposed joint meetings in Cleveland may be published simultaneously in the *Journal* of the Cleveland Engineering Society and our own Journal, with mutual benefit. This *Journal* is a noteworthy feature of the local organization, having achieved wide repute in the field of technical periodicals.

The Cleveland spirit portends a growing enthusiasm in other localities, as the Society is intensely interested in spreading the movement to establish Sections which shall take an active part in the work of the local organizations in their districts.

New Officers of Sections

The following members of Executive Committees for the fiscal year 1918-1919 have been recorded by the Committee on Local Sections:

Atlanta: Robert Gregg, Chairman; William J. Neville, Secretary; H. J. Hinchey, C. P. Poole, Earl F. Scott.

Baltimore: A. E. Walden, Chairman; William L. De Baufre, Vice-Chairman; A. G. Christie, Secretary-Treasurer; W. W. Varney, J. C. Smallwood.

Birmingham: W. P. Caine, Chairman; Paul Wright, Vice-Chairman, James W. Moore, Secretary; H. M. Gassman, W. Lee Roueche.

Boston: W. G. Starkweather, Chairman; Elmer Smith, Secretary; A. C. Ashton, Treasurer; W. W. Crosby, George P. Aborn, Edward M. Jennings.

Buffalo: H. B. Alverson, Chairman; H. P. Parrock, Vice-Chairman; W. W. Boyd, Secretary; F. W. Bailey, Kester Barr.

Chicago: C. E. Lord, Chairman; P. A. Poppenhusen, Vice-Chairman; A. L. Rice, Secretary; Robert Quayle, J. J. Merrill.

Cincinnati: George W. Galbraith, Chairman; E. A. Muller, Vice-Chairman; J. T. Faig, Secretary-Treasurer; A. L. Jenkins, H. M. Norris.

Connecticut: To be announced.

Bridgeport Branch: E. L. Fletcher, Chairman; Arthur Brewer, Vice-Chairman; J. C. Kingsbury, Treasurer; C. F. MacGill, Secretary; J. Coulter, H. E. Wells.

Hartford Branch: Charles S. Blake, Chairman; Frank E. Howard, Vice-Chairman; M. D. Church, Secretary-Treasurer; C. L. Grohmann, B. M. V. Hanson, W. H. Honiss, S. F. Jeter, H. P. Maxim, C. H. Veeder.

Meriden Branch: C. K. Decherd, Chairman; C. N. [illegible], Jr., Secretary-Treasurer; F. L. Rowntree, J. A. Hutchinson, F. L. Wood.

New Haven Branch: J. A. Norcross, Chairman; E. H. Lockwood, Secretary; S. H. Barnum 2d, A. C. Jewett, F. L. Mackintosh, E. Pugsley.

Waterbury Branch: To be announced.

Detroit: E. C. Fisher, Chairman; E. J. Burdick, Vice-Chairman; F. H. Mason, Secretary-Treasurer; J. C. McCabe, E. J. Frost.

Erie: M. W. Sherwood, Chairman; C. M. Spalding, Vice-Chairman; R. Conrader, Treasurer; J. St. Lawrence, Secretary.

Indianapolis: L. W. Wallace, Chairman; W. A. Hanley, Vice-Chairman; B. G. Mering, Treasurer; Charles Brossman, Secretary; Gilbert A. Young, F. C. Wagner.

Los Angeles: Charles H. McGwire, Chairman; T. J. Royer, Secretary; Charles Burnham, Fred J. Fischer, J. A. Wintroath.

Milwaukee: W. M. White, Chairman; F. H. Dorner, Secretary; L. H. Strothman, W. Hutchens, M. A. Beck.

Minnesota: J. A. Teach, Chairman; R. B. Whitacre, Vice-Chairman; Ray Mayhew, Secretary-Treasurer; H. LeRoy Brink, J. V. Martenis.

New Orleans: H. L. Hutson, Chairman; E. W. Carr, Jr., Secretary-Treasurer; R. T. Burwell, W. E. Moses, J. S. Barelli.

New York: W. W. Macon, Chairman; H. D. Egbert, Secretary; S. M. Marshall, A. J. Baldwin, G. K. Parsons, W. C. Brinton.

Ontario: R. W. Angus, Chairman; C. B. Hamilton, Secretary; James Milne, J. H. Billings, G. V. Ahara.

Philadelphia: C. N. Lauer, Chairman; J. P. Mudd, Secretary; H. B. Taylor, L. F. Moody, W. B. Murphy, L. H. Kenney.

St. Louis: Lewis Gustafson, Chairman; J. P. Morrison, Secretary; George B. Evans, H. R. Setz, R. L. Radcliffe.

San Francisco: E. C. Jones, Chairman; Elgin Stoddard, Vice-Chairman; George L. Hurst, Secretary; H. S. Markey, J. H. Hopps.

Worcester: E. C. Mayo, Chairman; George N. Jeppson, Albert W. Darling, H. P. Fairfield, George E. Williamson, Frederick Fosdick.

BIRMINGHAM

September 9. An organization and business meeting was held in the Tutwiler Hotel. An open meeting for the latter part of October was decided upon.

James W. Moore,
Corresponding Secretary.

CHICAGO

A joint meeting of the Chicago Section of the A.I.E.E. and the War Committee of Technical Societies of Chicago was held on September 23. Col. P. Junkersfeld, Mem. Am. Soc. M. E., addressed the meeting on the subject of Emergency Conservation for the War Department in the U. S. The lecture was fully illustrated.

Joseph Harrington, Mem. Am. Soc. M. E., Fuel Administrative Engineer for the State of Illinois, and Dr. H. M. Nichols, Mem. Am. Soc. M. E., secretary of the Chicago Section of the A.S.M.E., spoke at the dinner given to Mr. C. E. Drayer, the new secretary of the American Association of Engineers, at the City Club on September 4.

Arthur L. Rice,
Corresponding Secretary.

DETROIT

The opening meeting of the season of the Detroit Engineering Society was held on September 6. H. H. Esselstyn, Mem. Am. Soc. M. E., addressed the meeting on the Hog Island Shipyard.

September 20. The Detroit Engineering Society held a meeting in the Detroit Board of Commerce, which was addressed by Professor Henry S. Jacoby, on the subject of Recent Progress in Bridge Construction.

F. H. Mason,
Corresponding Secretary.

CONNECTICUT

Bridgeport Branch

September 9. Through the courtesy of the Bridgeport Chamber of Commerce all members of the Bridgeport Branch were invited to a luncheon at the Stratfield Hotel, where a talk was given by Charles A. Otis, Chief of the Section on Resources and Conversion, War Industries Board, the subject being Industry and the War.

E. L. Fletcher,
Chairman.

MILWAUKEE

September 11. The Engineers' Society of Milwaukee held a meeting in the City Club, at which E. R. Shepard, Associate Electrical Engineer of the United States Bureau of Standards, gave an illustrated talk on The Work of the Bureau of Standards, With Special Reference to Local Electrolysis Surveys. The meeting was preceded by a subscription dinner at the Club.

Fred H. Dorner,
Secretary, Engineers' Society of Milwaukee.

MINNESOTA

September 3. An organization meeting was held at the Midway Branch of the St. Paul Association of Commerce. Arrangements have been made to hold regular meetings in the clubrooms the first Monday of each month.

Ray Mayhew,
Corresponding Secretary.

NEW YORK

September 17. Marcel Knecht, member of the French High Commission in the United States, addressed a meeting at the Engineering Societies' Building, to which members of the other national societies were specially invited. The subject of the address was The Supreme Effort of the French War Industries—Franco-American Industrial Coöperation During and After the War. Brigadier-General L. B. Kenyon, of the British War Mission, recently returned from a trip to the front, told of his experiences, including his observations of salvaging work and machine and repair shops. He discussed particularly the necessity, even yet not thoroughly appreciated, for precision work in manufacturing ordnance.

H. D. Egbert,
Corresponding Secretary.

PHILADELPHIA

August 14. An organization meeting was held in the Engineers' Club, at which meetings were planned for each month, through May. The Section has also appointed several sub-committees on research, membership, public relations, organization, papers, meetings and boundary of the territory to comprise the Section.

John P. Mudd,
Corresponding Secretary.

SAN FRANCISCO

A joint council of the engineering societies of San Francisco, including the A.S.C.E., the A.I.E.E., the A.S.M.E., the A.I.M.E. and A.C.S., has been organized with C. D. Marx as chairman, E. C. Jones and E. C. Hutchinson, vice-chairmen, N. A. Bowers, secretary, and E. O. Shrave, assistant secretary.

The organization is the outcome of several meetings at which plans for more effective coöperation between societies have been worked out. Some of the expected changes are a closer touch among the members of the several associations, putting the several employment bureaus together in one central office, holding joint meetings to discuss subjects of common interest, coöperating in mailing notices for the sake of economy and consolidating headquarters at the Engineers' Club.

The first act of the joint council was the decision to urge upon the Governor of California the appointment of an engineer as member of the State Railroad Commission, which would "be regarded by the state as indicating a wish to place the public service on the highest plane of efficiency and would be creditable both to the appointing power and to the engineering profession."

George L. Hurst,
Corresponding Secretary.

NECROLOGY

GEORGE WILLIAM DICKIE.

A Tribute by C. E. Grunsky[1]

Those who knew Mr. George W. Dickie mourn with his family. His death has removed from the engineering profession a man of rare attainments and attractive personality whose achievements in his life work of shipbuilding and whose writings on related subjects have given him an international reputation.

When in the Spanish-American war the *Oregon* of the United States Navy made that famous dash around South America from Pacific Coast waters to the Caribbean Sea, he became known in every household of this country as the "Builder of the *Oregon*."

He was called to his final rest on August 17, without warning and while still remarkably vigorous in mind and body and actively engaged in the service of the United States as Chief Inspector at the Moore and Scott Shipbuilding Yards, Oakland, California.

George W. Dickie

Having known Mr. Dickie for over thirty years and being deeply appreciative of his human qualities, I may be permitted a few words relating to his character and his professional standing without attempting a complete review of his achievements. No one ever came into close contact with Mr. Dickie whether socially, professionally, or in business without profiting by such contact. His personality was an inspiration. Always kindly and helpful and absolutely fair in his dealings with his fellow-men, he could claim the confidence, respect and esteem alike of those whose industrial affairs he directed and those who worked under him. This varied and long experience and his contact with affairs and with men of prominence from all parts of the world and a habit of close observation coupled with a retentive mind and a happy faculty of expression made Mr. Dickie a most charming companion and an entertaining writer. As related by him with a flavor of Scotch humor, the simple story of how as a boy upon the suggestion of his schoolmaster, who spent much time on scientific work, he acquired the necessary lenses and built himself a telescope to view a comet then in the sky, and how at a penny a look he turned its construction to financial profit, is not alone a delightful reminiscence but a forecast of his later connection with the installation of the great Lick telescope on Mt. Hamilton, for which he designed and built the dome in which it is housed.

Mr. Dickie was born in Arbroath, Scotland, on July 17, 1844. He came to the United States with his parents in 1869 and in the same year reached San Francisco. Very soon after his arrival here he had an opportunity of showing his confidence in his ability to do well any problem of mechanical construction that was presented. Answering an advertisement for some one skilled in the construction of a gas plant, he was employed to erect one at North Beach. By following the usual practice of benefiting by the experience of others as related in professional papers and particularly by reference to the details of a gas plant recently completed in an English city and well described in a Scotch journal, the work was carried to successful completion.

Soon thereafter a mechanical engineer to design marine engines was wanted—possibly at the Risdon Iron Works, San Francisco, but the place does not matter—and Mr. Dickie presented himself. "You will not do," he was told, "we need a mechanical engineer and you are a gas engineer." Thereupon he confessed that his attainments were all along the lines of mechanical engineering, he having served his apprenticeship in a railroad engineering shop in Scotland with special attention to locomotive construction. He was thereupon or soon after employed at the Risdon Iron Works where his work took a wide range. [He designed the first successful triple-expansion engine ever built in the United States, and within a few years had made himself famous by designing the first Scotch marine boiler on the Pacific Coast and also the first successful compound steam engine. Several of the latter are still in operation, notably those on the old steamers *Santa Cruz* and *Gypsy*.] On one occasion he secured for his firm a large contract for mining machinery, making a proposition which was accepted as against another proposal by Mr. Irving M. Scott, of the Union Iron Works. This kind of successful competition was not to Mr. Scott's liking and resulted in his making an offer to Mr. Dickie, which was accepted. He thus became a member of the staff of a concern in which he had ample opportunity to apply his constructive genius. He was manager of the Union Iron Works from 1883 to 1905 [and during that period designed many privately owned ships, in addition to the following vessels for the Government: Battleships *Oregon*, *Wisconsin* and *Ohio*; the cruiser *Olympia*, later the flagship of Admiral Dewey; the cruisers *South Dakota*, *San Diego*, *Charleston* and *Milwaukee*, the gunboat *Wheeling* and destroyers *Paul Jones*, *Preble* and *Perry*.]

As a narrator of his personal experiences he was unique. He knew how to present them in a humorous vein and with a lesson nicely turned. And he was always ready, when opportunity was presented, to let others have the benefit of this fund of experiences which seemed inexhaustible. How effectively he could make his point appears from the following which happens to be before me. After returning from the Columbian Exposition at Chicago in 1893, he told the Technical Society of the Pacific Coast of his impressions and in the course of his remarks, to drive home the fact that local conditions must be duly weighed, he related the following occurrence:

"One day at the engineering congress in discussing a paper on river-steamboat construction I was endeavoring to point out the advantage of compounding stern-wheel engines, recommending tandem compounds on each side, either condensing or non-condensing, when the author of the paper remarked that first cost was the most important consideration in the construction of a western river steamboat, efficiency or durability being of secondary importance. 'But,' said I, 'the everyday expense of running must

[1] Mem.Am.Soc.C.E.; President, American Engineering Corporatiton, San Francisco, Cal. [Certain slight additions, in brackets, have been made to Mr. Grunsky's sixth paragraph.—Editor.]

be an important matter especially where transportation is effected so cheaply. 'Why,' said the author of the paper, 'I am afraid that the gentleman from the Pacific Coast has had but a small experience with western river practice. As an example of economy let me give you an instance of a freight stern wheeler in my district that made her daily runs for the last season of eight months on a total expense of \$2.25 for fuel, and this expense was caused by the carelessness of the crew one night in not securing wood enough for the next day's run, necessitating the captain's buying enough to last until dark, as his method of taking on fuel would not work in daylight. In this case what would be the advantage of compounding?'"

That Mr. Dickie had an eye to the esthetic even in the design of the engine or other machinery, can hardly be better expressed than in his own words:

"I am often told that the useful only should be retained in any design. That is true, but who can say what is useful? Your best poet says:

'Nothing useless is or low,
Each thing in its place is best;
And what seems but idle show
Strengthens and supports the rest.'"

And then, after referring to several illustrations, he asks the question: "In regard to our other surroundings, we are not satisfied with the bare necessities of existence, and why should we be so in mechanics?"

And so we find, too, that Mr. Dickie was a great lover of books and took much pleasure in collecting rare volumes. It was quite pathetic to hear him tell how his valued collection was destroyed in the San Francisco earthquake and fire of 1906. At that time Mr. Dickie was in the East supervising the construction of ships that were being built from his designs. The collection of rare books had been boxed and deposited for safe keeping at Mr. Dickie's office in San Francisco, where they were reached by the fire and destroyed. Had they been left at the Dickie home in San Mateo, they would have been preserved. A year later there came from England an agent of a dealer in rare books commissioned to purchase from Mr. Dickie certain rare volumes which it was known were in his collection. He was prepared to pay some thousands of dollars, and, like Mr. Dickie, was distressed when he learned that the trade could not be made because the books no longer existed.

Mr. Dickie wrote many papers bearing upon marine architecture and engineering, and also on matters relating to the American merchant marine. He was recognized as an authority on such matters and was widely quoted. He was thoroughly imbued with American ideals and was ever ready to serve this country to the limit of his ability. Immediately on the outbreak of the war he offered his services to the U. S. Government. His fertile brain was active and he sent on a number of propositions dealing with the protection of allied shipping against attacks by submarines. He was appointed chief inspector for the Government at the Moore and Scott Shipbuilding Works as already stated, and despite his 71 years was rendering most efficient service when the last call came.

He possessed in a high degree the best character traits of the Scotchman. An idea of his probity and fairness to his fellowmen will appear from the following circumstance related to the writer some months ago. Mr. Dickie had some time in the seventies loaned a few hundred dollars to a stranded Canadian who gave his note for the loan and left as a pledge certain shares of stock of no market value in mines located on the Comstock Lode. Neither interest nor capital were repaid. The note outlawed. Meanwhile the Comstock properties came into prominence, the value of stock was soaring, and one day it occurred to Mr. Dickie to take the stock which he held to the Nevada Bank to ascertain whether it had any value. When he was told that it was worth \$75,000 he was so taken by surprise that his knees came near giving away and he with difficulty withdrew from the bank. The stock was at once sent to the former owner, from whom, despite a fair offer, Mr. Dickie would accept nothing but a repayment of the loan and interest.

Mr. Dickie has been a useful man in the community. He had the esteem and love of those who knew him. He has left a place which none other can fill.

Mr. Dickie became a member of our Society in 1892. From 1895 to 1898 he held the office of Manager of the Society. He was also a life member of the Technical Society of the Pacific Coast, and a member of the California Academy of Sciences and the American Society of Naval Engineers.

ADOLPH FABER DU FAUR

Adolph Faber du Faur was born on March 27, 1826, in Wasseralfingen, Württemberg. After his preparatory education he entered the University of Tübingen, and upon graduation was employed for a year in Belgium at the Cockerill works. He was then appointed as assistant to his father, Wilhelm von Faber du Faur, who was permanent director of the government iron works in Wasseralfingen, and under whose management they became world-known.

In January 1851 Mr. Faber du Faur resigned from his position in Wasseralfingen and came to the United States, where he was first employed in Trenton, N. J. His next position was with the Balbach Smelting & Refining Co., Newark, and a little later he was connected with the New Jersey Zinc Co.

In 1857 he went to Washington and was there engaged until 1861 on the United States Capitol extension, the Post Office extension and the Washington Aqueduct, under Captains M. C. Meigs and V. B. Franklin. In 1861 he was called upon to undertake engineering work for the Government and had charge of the construction of Fort Stanton. During the Civil War he was under General Meigs in the Quartermaster Department and was appointed special agent of the Quartermaster Department for steam transportation. In 1867 he resigned from the service and went to Richmond, Va., there to take charge of the Westham Furnace. In 1868 he returned to New York and opened an office as mining and consulting engineer and expert in patent causes. He was actively engaged in this work up to within a few years ago, when age compelled his retirement. He died on August 17, 1918. He became a life member of the Society in 1880.

ALBERT BLAUVELT

Albert Blauvelt was born in Philadelphia, Pa., on June 7, 1862. After graduation from the Kingston Academy, Kingston, N. Y., he served an apprenticeship in the drafting room of F. L. Roberts, New York. From 1879 to 1883 he was connected with the McEntee Locomotive Works, Rondout, N. Y., and with the West Point Foundry. The following year he was in the employ of the Lidgerwood Co., Brooklyn, N. Y. He was next associated as designer and expert draftsman with the Fall Steam Pump Co., the Cold Springs, N. Y., Rifle Works, and the Baldwin Locomotive Works, respectively. From 1890 to 1894 he was with the Edison Electric Co., Orange, N. J., and then with the American Oil Co., as engineer in the insurance department. In 1894 he entered the employ of the Western Factory Insurance Association, Chicago, Ill., and at the time of his death, January 4, 1918, held the position of associate manager.

Mr. Blauvelt was among the pioneers to bring into prominence the profession of fire-protection engineering and in that profession he was recognized as an authority. He became a member of our Society in 1896.

JOHN J. MULLANEY

John J. Mullaney was born in Ireland in 1864. He was brought to this country when a child and was educated in the schools of New York City, later attending Cooper Union. His apprenticeship was spent with the Delamater Iron Works, New York, from 1880 to 1884. The next three years he was employed as a machinist and in 1888 he became superintendent of the tool and manufacturing departments of the Columbia Typewriter Co. and the following year was associated with the Smith Premier Typewriter Co. About 1890 he became associated with the Brosius Sewing Machine Co. as superintendent, resigning in 1893 to take a similar position with the Garvin Machine Co. Later he was president of the Ideal Opening Die Co., New York. At the time of his death Mr. Mullaney had consulting offices in New York.

He became a member of the Society in 1901. He died suddenly in the early part of June in Redbank, Cal.

HOWARD L. COBURN

Howard L. Coburn was born in Patten, Me., in 1867. He was graduated in 1887 from the Massachusetts Institute of Technology

and up to the time of his death had been associated in its development.

Mr. Coburn designed some of the largest cotton mills and power plants in New England and until 1904 devoted himself to that phase of his profession. About that time he became associated with the Ambursen Construction Co., New York, as chief engineer and director, and in that capacity began the building of dams.

One of the most important of his works was the construction of the Guayabal Dam for the United States Irrigation Service in Porto Rico. He also put the Bassan Dam across the Bow River in Alberta for the Canadian Pacific Railway, and the Jordan River Dam on Vancouver Island, B. C. In this country he built the Shoshone and Laprelle Dams in Wyoming, the dam at Akron, Ohio, and the Pittsfield Dam, located at Pittsfield, Mass.

In addition to this work he was associated as consulting engineer with Henry L. Doherty & Co., E. W. Clarke & Co. and H. M. Byllesby & Co.

Mr. Coburn was a member of the American Society of Civil Engineers, the Engineers' clubs of New York and Boston and of the Technology Club. He became a member of the Society in 1901. He died on June 19, 1918.

WILLIAM KENT

William Kent, eminent consulting engineer, author, educator, editor, and former manager and vice-president of the Society, died at his summer home in Gananoque, Ont., on September 18.

Professor Kent was born in Philadelphia in 1851 and was educated at the Central High School of that city, and at Stevens Institute of Technology, from which latter he was graduated in 1876. From 1877 to 1879 he was editor of the *American Manufacturer and Iron World*, of Pittsburgh, and from 1879 to 1890 he served as mechanical engineer with several manufacturing concerns. From 1895 to 1903 he was associate editor of *Engineering News* and for the following five years was dean of the L. C. Smith College of Applied Science, of Syracuse University. From 1910 to 1914 he was editor of *Industrial Engineering*. While practicing from an early day as consulting engineer, he was nevertheless most widely known in the engineering world as the author of The Mechanical Engineers' Pocket-Book, of which nine editions, aggregating more than 100,000 copies, have been printed.

A more extended account of Professor Kent's professional career will appear in the next issue of The Journal.

ROLL OF HONOR

Bergstrom, Harry E., First Lieutenant, Co. B, 69th Regiment Engineers, Fort Myers, Va.

Beyer, O. S., Captain, Chemical Warfare Service, U. S. Army, assigned to the American University Experiment Station, Washington, D. C.

Bissell, Albert W., Artillery Training School for Officers, Camp Zachary Taylor, Ky.

Bohnstengel, Walter, 109th Mobile Ordnance Repair Shop, Camp Cody, N. M.

Boynton, John E., Captain, Engineers, U. S. Army, assigned to Camp Humphreys, Va.

Brewer, Allen F., Chief Machinist's Mate, Engineer Officers' Material School, U. S. Naval Reserve Force.

Buck, Irwin, Captain, Ordnance Department, U. S. Army, assigned to Willys-Overland Co., Toledo, O.

Carroll, E. J., Lieutenant, Bureau of Steam Engineering, Navy Department.

Cary, James W., Private, 48th Co., Coast Artillery Corps, U. S. Army, San Francisco, Cal.

Case, George S., Major, Chemical Warfare Section, U. S. Army.

Cathcart, William L., Lieutenant Commander, U. S. Navy, assigned to special duty in Bureau of Steam Engineering, Washington, D. C.

Conrad, H. V., Captain, Inspection Division, Ordnance Department, U. S. Army.

Dorrance, George W., Second Lieutenant, Air Service, U. S. Army.

Evans, Melvin J., Second Lieutenant, Ordnance Department, U. S. Army, assigned to Savanna Proving Ground, Savanna, Ill.

Everitt, I. D., Lieutenant, Ordnance Department, U. S. Army, assigned to Aberdeen Proving Grounds, Md.

Geddis, Robert H., Corporal, 16th Co., 152d Depot Brigade, Camp Upton, N. Y.

Hanson, John J., First Lieutenant, Ordnance Department, U. S. Army.

Haselton, Philip H., Second Lieutenant, Ordnance Department, U. S. Army, assigned to Aberdeen Proving Grounds, Md.

Hill, George F., Captain, Chemical Warfare Section, Ordnance Department, U. S. Army.

Holden, Edward A., Chief Machinist's Mate, U. S. Steam Engineering School, Pelham Bay Naval Training Station, 2nd Co., 6th Regiment.

Houston, H. A., Captain, Engineers, U. S. Army.

Keller, John O., Second Lieutenant, Ordnance Department, U. S. Army; assigned as Materiel Instructor, Ordnance Supply School, Camp Hancock, Ga.

Kerr, Charles P., First Lieutenant, Air Service, U. S. Army, Technical Section, American Expeditionary Forces, France.

Kniese, First-class private, Engineering Section, Ordnance Department, U. S. Army.

Lynd, Roy E., Captain, Ordnance Department, U. S. Army, assigned to the Tredegar Co., Richmond, Va.

Malcome, George H., Captain, Chemical Warfare Service, Gas Defense Division, U. S. Army.

Marshall, K. L., First Lieutenant, Chemical Warfare Service, U. S. Army, American Expeditionary Forces, France.

Marshall, W. A., Private, Machine Gun Company Detached Service; American Wing, British G. H. Q., Machine Gun School, B. E. F., France.

May, J. T. L., First Lieutenant, Chemical Warfare Service, U. S. Army, assigned to Fourth Battalion Headquarters, Edgewood Arsenal, Edgewood, Md.

Miles, Dale S., Private, First class, Quartermaster Mechanical Repair Shop, Fort Sam Houston, Tex.

Penney, R. L., Major, Ordnance Department, U. S. Army; assigned to Rock Island Arsenal, Rock Island, Ill.

Prozan, Moses, Private, Mechanical Resources and Development Division, Chemical Warfare Section, U. S. Army, American University, Washington, D. C.

Reckerdres, Henry, Ensign, U. S. Navy, Submarine Service.

Reed, Melbourne O., Ensign, U. S. Navy, assigned to U. S. Naval Training Camp, 10th Regiment, Pelham Bay Park, N. Y.

Richmond, Julian, Lieutenant, U. S. Naval Reserve Corps, Paris, France.

Royer, Earl B., Private, Medical Detachment, 6th U. S. Cavalry, American Expeditionary Forces, France.

Ruddy, William, First Lieutenant, Inspection Division, Ordnance Department, U. S. Army.

Skinner, James D., Captain, Ordnance Department, U. S. Army.

Smith, Harry R., Candidate, Field Artillery Officers' Training Camp, Camp Zachary Taylor, Ky.

Stanton, Robert B., Jr., First Lieutenant, Engineers, U. S. Army.

Stockmann, E. B., Ensign, U. S. Naval Reserve Submarine Unit, 10th Regiment, U. S. Naval Reserve Force, Pelham Bay Naval Camp, New York.

Tait, Godfrey M. S., Captain, Chemical Warfare Service, U. S. Army.

Turley, Charles L., Lieutenant, 21st Engineers, U. S. Army.

Vincent, J. G., Lieutenant-Colonel, Air Service, U. S. Army; Airplane Engineering Department, Bureau of Aircraft Production.

Wadsworth, G. R., Major, Signal Corps, U. S. Army, Chief Engineer, Naval Aircraft Factory, Navy Yard, Philadelphia, Pa.

Watkins, Roy A., Ensign, U. S. Naval Reserve Force, Aviation Department, assigned to Bureau of Steam Engineering, Division of Aeronautics, Washington, D. C.

Yates, Sheldon S., Candidate, Field Artillery Officers' Training Camp, Camp Zachary Taylor, Ky.

Young, Charles M., Ordnance Training School, Fort Slocum, New York.

Fourth Liberty Loan

THE people of the United States are asked to subscribe for $6,000,000,000 of bonds at 4¼ per cent interest, which will mature on October 15, 1938, unless the Government exercises its right to redeem the issue on or after October 15, 1933. Bonds will be dated October 24, 1918, and the first interest coupon for 173 days will be payable April 15, 1919. Interest dates thereafter will be October 15 and April 15.

Denominations of bonds: Coupon and registered bonds will be issued in amounts of $50, $100, $500, $1,000, $5,000, $10,000; and registered bonds in amounts of $50,000 and $100,000.

The interest on $30,000 of bonds of the Fourth Liberty Loan is exempt, until two years after the termination of the war, from surtaxes and excess profits and war-profits taxes. The bonds are also permanently exempt from all other federal, state, and municipal taxation, except estate and inheritance taxes.

Initial payment will be 10 per cent payable with the subscription and subsequent payments will be as follows: 20 per cent on November 21, 1918; 20 per cent on December 19, 1918; 20 per cent on January 16, 1919; 30 per cent on January 30, 1919. Payment may be made in full at time of subscription or on any subsequent installment date. *The campaign started on September 28 and ends on October 19.*

Comparative Data of Three Previous War Loans

First Liberty Loan, May 5 to June 15, 1917: subscription invited, $2,000,000,000; amount subscribed, $3,716,322,450; allotment, $2,000,000,000. Interest, 3½ per cent.

Second Liberty Loan, October 1 to October 27, 1917: subscription invited, $3,000,000,000; amount subscribed, $4,617,532,300; allotment, $3,808,766,150. Interest, 4 per cent.

Third Liberty Loan, April 6 to May 4, 1918: subscription invited, $3,000,000,000; amount subscribed, $4,176,517,550; allotment, full amount subscribed. Interest, 4¼ per cent.

LIBRARY NOTES AND BOOK REVIEWS

REVIEWS of books of special importance to mechanical engineers by members of the Society and those particularly qualified, brief descriptive notes of accessions to the Library of the United Engineering Society, items of interest relating to the Library's activities, etc.

Bookkeeping and Cost Accounting for Factories. By William Kent, M.E., Sc.D., Mem.Am.Soc.M.E. John Wiley & Sons, Inc., New York, 1918. Cloth, $8\frac{1}{4}$ x 10 in., 261 pp., profusely illustrated with forms. $4 net.

This recently written work differs materially from any other on the subject that has been called to my attention.

The aim of the author has been to present his subject to engineers, manufacturers and students in a manner that would appeal to practical men and at the same time combine the theoretical principles of accounting in a way to be easily understood and readily followed by those far enough advanced in a knowledge of factory management.

The book is peculiarly well fitted to serve as a textbook for the management and accounting departments of large manufacturing companies, especially those engaged in metal industries, as the problems of bookkeeping and cost finding have been analytically handled, due consideration being given to modern methods and the developments of systems that have stood the acid test and have become practically standard methods in general use wherever their special merit has proved them especially applicable to certain classes of business.

Mr. Kent has succeeded in working out many clearly detailed examples descriptive as to the accounting and cost methods that should be followed, all of which represent practical methods that have been successfully used and can be easily modified and applied to varying manufacturing conditions and requirements.

The chapters on Cost Finding Methods; Distribution of Burden; Depreciation, Inventory Valuation and Appraisals; Charting of Statistics; Problems and Difficulties *re* Standard Costs, are very well written, and the mass of information culled from many reliable sources, combined with Mr. Kent's well-known analytical method of treating subjects of this kind, makes the work one which places before the reader the most concise and up-to-date treatment of the subject that has yet been published in a single volume.

It is this feature of the new work that will appeal to the constructive reader, as it enables him to grasp clearly in a minimum time the various phases of any problem in bookkeeping and cost accounting in which he may be interested. It is essentially a work of reference and will be consulted more often than the usual work of this character that has been published to develop one theory and leaves the reader to wander through many other publications before he can secure a comprehensive grasp of the subject.

To the factory accountant anxious to improve his methods of accounting, the chapters on Factory Accounting, Cost Accounting, Modern Accounting Systems for Steel Works, etc., furnish a fund of knowledge that is readily understood and capable of easy modifications to meet varying conditions.

On the whole, I feel that Mr. Kent has succeeded admirably in gathering together the best ideas and methods in use today, supplementing these by his own views, clearly expressed and easily followed, and has produced a book that more nearly represents a standard textbook on factory bookkeeping and cost accounting than any other published to date.

Albert Walton.

Aeroplane Construction and Operation. Including Notes on Aeroplane Design and Aerodynamic Calculation, Materials, Etc. A Comprehensive Illustrated Manual of Instruction for Aeroplane Constructors, Aviators, Aero-Mechanics, Flight Officers and Students. Adapted Either for Schools or Home Study. By John B. Rathbun. Stanton and Van Vliet Co., Chicago, 1918. Cloth, 5 x 8 in., 426 pp., illus., pl., charts, diag., tables. $2.

The author has attempted to produce a book standing between the popular descriptive work and the mathematical engineering treatise, which will meet the needs of aviators and airplane builders. The volume covers the subject concisely and simply with the use of only elementary mathematics.

Allen's Commercial Organic Analysis. A Treatise on The Properties, Modes of Assaying, and Proximate Analytical Examination of the Various Organic Chemicals and Products Employed in the Arts, Manufactures, Medicines, etc., with Concise Methods for the Detection and Estimation of Their Impurities, Adulterations, and Products of Decomposition. Vol. IV. By the Editors and the following Contributors: M. Bennett Blackler, E. W. Lewis, T. Martin Lowry, Ernst J. Parry, Henry Leffmann, Charles H. Lawall. Fourth edition, entirely rewritten. Edited by W. A. Davis and Samuel S. Sadtler. P. Blakiston's Son & Co., Philadelphia (copyright 1911, reprinted 1917). Cloth, 6 x 9 in., 466 pp., tables. $5.

The subject has been divided between a number of authorities and much new matter has been included, so that the volume forms a convenient compendium of present knowledge on the subject.

Chemical Control of Gas Manufacture. Practical Instruction in Gas Works Chemistry for Superintendents, Foremen and Chemists. Part I. Practical Application. By W. M. Russell. Part II. Elementary Chemical Theory. By F. Wills. The Gas Age, New York, 1916. Cloth, 5 x 8 in., 152 pp., 47 illus., 1 pl., 18 tables. $1.50.

Devoted to a discussion of the methods for controlling gas-works processes by the use of chemistry, giving the most recent and reliable tests and analyses and explaining the methods used. Adapted to the requirements of the men in the smaller plants.

The Design of Aeroplanes. By Arthur W. Judge. Whittaker & Co., New York, 1917. Cloth, 6 x 9 in., 242 pp., 90 illus., 67 tables. $4

This volume endeavors to fulfill the need for a compendium in which the principles underlying aeroplane design, from the standpoint of the mechanical engineer, are concisely presented and accompanied by the necessary data. A small amount of new matter has been inserted in this edition, typographical errors have been corrected and a chapter on fuselage design and construction added. Contains a bibliography.

Electrical Phenomena in Parallel Conductors. Vol. I. Elements of Transmission. By Frederick Eugene Pernot. First edition. John Wiley & Sons, Inc., New York, 1918. Cloth, 6 x 9 in., 332 pp., 82 illus., 35 tables. $4.

Gives the mathematical developments leading to solutions for a number of problems arising in connection with the transmission of electrical energy over metallic circuits. Deals with continuously alternating-current phenomena only and is intended to serve as an introduction to subsequent volumes deal-

ing with specialized forms of electrical transmission. There is an appendix containing formulae and tables.

Electrical Locking. By James Anderson. Simmons-Boardman Publishing Co., New York (copyright, 1918). 6 x 9 in., 219 pp., 210 illus. $2.

Describes in detail the various methods for the supplementary protection of a system of interlocking switches, the apparatus used, methods of wiring, etc. Portions of the book appeared in the *Railway Signal Engineer*.

A Handbook of Briquetting. By G. Franke, translated by Fred C. A. H. Lantsberry. Vol. II. Briquetting of Ores, Metallurgical Products, Metal Swarf and Similar Materials, Including Agglomeration. J. B. Lippincott Co., Philadelphia, 1918. Cloth, 6 x 9 in., 214 pp., 79 illus., 4 folded pl., 14 tables.

Describes the various materials briquetted, methods of briquetting and agglomeration, preparation of material, compression and subsequent treatment of briquets. A number of complete briquetting and agglomeration plants in Germany and Austria are shown in detail. Appendices to vols. 1 and 2 are included.

Handbook of Mathematics for Engineers. By Edward V. Huntington, with Tables of Weights and Measures by Louis A. Fischer. Reprint of Sections 1 and 2 of L. S. Marks's Mechanical Engineers' Handbook. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Flexible cloth, 5 x 7 in., 191 pp., illustrated, tables.

Designed to supply in compact form, accurate statements of those facts and formulæ of pure mathematics which are most likely to be of use to the worker in applied mathematics.

How Wooden Ships Are Built. A Practical Treatise on Modern American Wooden Ship Construction with a Supplement on Laying Off Wooden Vessels. By H. Cole Estep. The Penton Publishing Co., Cleveland, 1918. Cloth, 9 x 12 in., 101 pp., 201 illus., 6 tables.

This book is a revised publication of a series of articles that appeared in *The Marine Review*. It deals with methods of construction rather than with ship design and is intended for shipbuilders rather than for naval architects. A supplement on methods of laying down wooden ships is included.

Hydraulic and Placer Mining. By Eugene B. Wilson. Third edition, thoroughly revised. John Wiley & Sons., Inc., New York, 1918. Cloth, 5 x 8 in., 425 pp., 95 illus., 1 pl., 20 tables. $3.

The third edition contains much additional information intended to bring the work up abreast of the latest improvements in this industry. The book is designed to appeal not only to those actually engaged in placer mining, but also to those who wish to get the latest ideas on the subject.

Municipal Housecleaning. The Methods and Experiences of American Cities in Collecting and Disposing of their Municipal Wastes—Ashes, Rubbish, Garbage, Manure, Sewage, and Street Refuse. By William Parr Capes and Jeanne Daniels Carpenter, with an introduction by Cornelius F. Buns. E. P. Dutton & Co., New York, 1918. Cloth, 6 x 10 in., 232 pp., 16 tables (2 folded). $6.

Designed to furnish the information needed by those who are interested in the problems of the collection, care and disposal of municipal wastes. Also takes up the need for more efficient management and for the development of revenue-producing by-products. Intended to help public officials in selecting and operating the system best adapted to local conditions, and also to serve as a guide to the layman who wishes to inform himself about the methods of municipal housecleaning.

Ports and Terminal Facilities. By Roy S. MacElwee. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 315 pp., 118 illus., 1 folded map, 17 tables. $3.

Contents: The Nature of the Problem, The Relative Importance and Physical Characteristics of the World's Leading Ports, General Characteristics of a Well-Coordinated Seaport, Port Competition for Rail and Maritime Freight, The Harbor, Belt Railway and Competition at the Terminals, Lighterage, Cartage, Drays and Motor Trucks, Piers, Wharves and Quays, Wharf Equipment, Cargo Transfer and Handling, Shed Equipment, The Warehouse, Standard Package or Specialized Freight, Bulk Freight, Inland Waterways and the Seaport, The Industrial Harbor and Upland Development, The Free Port as an Institution, The Processes By Which the Free Ports of Hamburg and Bremen Were Created, Bigliography.

A revision of the material used in a course of lectures at the School of Business, Columbia University. Discusses some of the engineering and economic factors which determine the success or failure of a port.

Standard Cotton Mill Practice and Equipment. With Classified Buyer's Index. Published Annually by The National Association of Cotton Manufacturers, Boston, 1918. Cloth, 6 x 9 in., 203 pp., illus., tables. $1.50.

An annual encyclopedia, containing economic trade and engineering data of interest to mill executives. Contains also a classified directory of manufacturers of cotton-mill supplies and equipment.

Steam Engines. A Thorough and Practical Presentation of Modern Steam Engine Practice. By Llewellyn V. Ludy. American Technical Society, Chicago, 1917. 6 x 8 in., 192 pp., 103 illus., 1 pl., 8 tables. $1.

Treats of the theory and construction of various types of steam engines, and of their purchase, operation and testing. A non-mathematical treatise intended for stationary engineers and particularly adapted for home study.

Storrs. A Handbook for the Use of Those Interested in the Construction of Short-Span Bridges. By John W. and Edward D. Storrs. Published by the authors, Concord, N. H., 1918. Flexible cloth, 4 x 7 in., 40 illus., 20 tables. $1.

A small pocketbook containing designs and methods of construction of small highway bridges, culverts, etc. Intended to assist men without engineering training in the construction of such structures.

Uniform Cost Accounting for Steel Furniture Industry. Compiled by Erich W. Kath. The National Association of Steel Furniture Manufacturers, Cleveland (copyright, 1918). Cloth, 5 x 8 in., 106 pp., 5 forms.

The methods of ascertaining costs presented are the result of careful investigation of the conditions in different organizations. The systems recommended are in accord with the best practices of accounting and can, with minor changes, be adapted to the needs of the various concerns.

Water Rights Determination. From an Engineering Standpoint. By Jay M. Whitham. First edition. John Wiley & Sons, Inc., New York, 1918. Cloth, 6 x 9 in., 204 pp., tables. $2.50.

Intended to assist an owner of an indefinite water right in determining the meaning of his right as expressed in horsepowers, and the number of cubic feet of water per second to which he is entitled. Gives citations from representative writings and presents many tests and power determinations used by the author. A bibliography is included.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by October 15 in order to appear in the November issue.

CHANGES OF POSITION

Philip D. Wagoner, president of the General Vehicle Company, Long Island City, N. Y., has assumed similar duties with the Elliott-Fisher Company, Harrisburg, Pa.

Henrik Gaeger has accepted a position as assistant engineer in the engineering section of the Division of Steel Ship Construction of the Emergency Fleet Corporation, Philadelphia, Pa. He was formerly affiliated with the Prescott Company, Menominee, Mich.

George S. Wheatley has assumed the duties of efficiency engineer, Midvale Steel and Ordnance Company, Coatesville, Pa. He was until recently secretary to the vice-president of the Midvale Steel Company, Philadelphia, Pa.

Frank G. Frost, formerly general superintendent of the Houston Lighting and Power Company, Houston, Tex., has accepted the position of superintendent of power for the New Orleans Railway and Light Company, New Orleans, La. Both of these companies are subsidiaries of the American Cities Companies.

Ralph Earl, formerly associated with Morris Knowles, Inc., Pittsburgh, Pa., in the capacity of assistant engineer, has become connected with the Water Purification Board, Sewerage and Water Board, New Orleans, La.

Leland G. Knapp, until recently affiliated with the Harsh and Chapline Shoe Company, Milwaukee, Wis., as efficiency engineer, has entered the employ of the Wisconsin Motor and Manufacturing Company, of the same city.

John B. Wilkinson has become identified with the Federal Dyestuff and Chemical Corporation, Kingsport, Tenn., in the capacity of superintendent of heat, light and power. He was formerly draftsman with the Nordberg Manufacturing Company, East Milwaukee, Wis.

E. T. Spidy, formerly production engineer, Canadian Ingersoll-Rand Company, Sherbrooke, Canada, has accepted a similar position with the Canadian Pacific Railway Company, Angus Shops, Montreal, Canada.

Douglas K. Warner, efficiency engineer, New Departure Manufacturing Company, Burdett, N. Y., has become connected with the Sheffield Scientific School, Yale University, New Haven, Conn.

Jiles W. Haney has accepted the position of assistant professor of mechanical engineering, University of Nebraska, Lincoln, Neb. He was formerly affiliated with the experimental engineering department of Pennsylvania State College, State College, Pa.

Grant E. Furbush has resigned his position as instructor in industrial engineering at Pennsylvania State College, State College, Pa., and has accepted the position of mechanical engineer with the Fafnir Bearing Company, New Britain, Conn.

E. J. Heinen, formerly with the Strong and Scott Company, Minneapolis, Minn., is now efficiency engineer with the Minneapolis General Electric Company.

Charles J. Simeon, formerly with the Curtiss Aeroplane Company, Buffalo, N. Y., has accepted the position of employment manager with the Morgan Construction Company, Worcester, Mass.

F. W. Shumard, equipment and production engineer at the Utica, N. Y., plant of the Savage Arms Corporation, has accepted a similar position in Washington, D. C., in the maintenance division of the Motor Transport Corps.

Norman G. Hardy has become affiliated with the old Hickory Powder Plant, Jacksonville, Tenn. He was formerly connected with the Arizona Copper Company, Clifton, Ariz., as superintendent of power.

Hugo R. Pausin has resigned his position as superintendent, E. W. Bliss Company, Brooklyn, N. Y., to take a position as production manager, Metropolitan Engineering Company, Brooklyn, N. Y., on a trench-warfare contract for the United States Government.

Francis J. McGrail, formerly foundry superintendent, Struthers-Wells Company, Tonawanda, N. Y., is now in the employ of the Walker Foundry Company, Erie, Pa., in the capacity of general superintendent.

George D. Reynolds has resigned his position as machine designer at Edgewood Arsenal, Baltimore, Md., to accept the position of works manager of the Quickwork Company, St. Marys, Ohio, manufacturers of rotary shears, sheet and plate metal working machinery, etc.

Conrad H. Rapp, formerly associated with Hoggson Brothers, New York, as assistant manager, designing and engineering department, has assumed the duties of project manager, Bureau of Industrial Housing, officially the U. S. Housing Corporation.

Herbert D. Mozeen has severed his connection with the Syracuse Supply Company, Syracuse, N. Y., and has become identified with the Bureau of Aircraft Production, Dayton, Ohio.

Frank L. Glynn, formerly associated with the Curtiss Aeroplane and Motor Corporation, Buffalo, N. Y., has accepted the position of superintendent of the Training Department, Ordnance Department, Production Division, Philadelphia, Pa.

Frank Sawford, until recently chief engineer, electrical and mechanical operations, Canadian Collieries, Union Bay, B. C., Canada, has become affiliated with the Taylor Engineering Company, Ltd., Vancouver, B. C., Canada.

Arthur B. Coates has resigned the position of instructor in mechanical engineering at the University of Idaho, Moscow, Idaho, and has become connected with the experimental engineering department of the Ford Motor Company, Detroit, Mich.

Walter F. Jay has resigned his position as works manager of the Power Specialty Company, Dansville, N. Y., after an association of 13 years, to accept the position of production engineer, Production Division, War Department, Rochester District Ordnance office.

Walter E. Wollheim has severed his connection with the engineering department of the Nathan Manufacturing Company, Flushing, L. I., to assume the duties of president and mechanical engineer of the Alloy Foundry and Machine Corporation of New Rochelle, N. Y.

William W. Conner, formerly with the engineering department of the Eastman Kodak Company, Rochester, N. Y., has accepted a position as power superintendent at the Chrome, N. J., plant of the U. S. Metals Refining Company.

Arthur J. Coldwell, formerly superintendent of the Coldwell Lawn Mower Company, Newburgh, N. Y., has assumed the position of production engineer, Ordnance Department, U. S. A., New York.

R. H. Robinson, until recently superintendent of the metal division of the Standard Aircraft Corporation, Elizabeth, N. J., has become associated with the Land Products Company, Whitestone, L. I., N. Y., manufacturers of aircraft propellers, in the capacity of production manager.

Alexander Vallance has become connected with the shell department of the American Machine and Manufacturing Company, of Atlanta, Ga. He was formerly assistant professor of experimental engineering, Georgia School of Technology, Atlanta, Ga.

Albert P. Leonard, assistant chief engineer, Honolulu Iron Works Company, New York, has become affiliated with the engineering division of the Bureau of Aircraft Production, Dayton, Ohio.

Gilbert R. Haigh has taken up work in the U. S. Ordnance Department, as supervisor of production in the Saginaw, Mich. district. He was formerly connected with the Wilt Engineering Company, Detroit, Mich., in the capacity of production engineer.

ANNOUNCEMENTS

W. J. Schlacks, formerly general manager of McCord and Company, Chicago, Ill., announces that he has purchased the McCord locomotive lubricator and has incorporated the Locomotive Lubricator Company for the manufacture and sale of the Schlacks system of locomotive force-feed lubrication.

William P. Bixby has become affiliated with the Blaw-Knox Company, Pittsburgh, Pa.

Elmo J. Miller, consulting engineer, of Santiago, Cuba, has assumed the position of general manager, Compañie Azucarera Oriente, Xavier, Oriente, Cuba.

David F. Atkins has become associated with the Lord Electric and Lord Construction Companies, New York, in the capacity of mechanical engineer.

F. H. Rosencrants has accepted the position of mechanical equipment inspector, American International Shipbuilding Corporation, Hog Island, Pa.

John G. Schabert has been promoted to the position of assistant chief engineer of the Colt's Patent Fire Arms Manufacturing Company, Hartford, Conn.

E. L. Consoliver has been engaged in army training work since April 8, as chief instructor in the starting, lighting and ignition division in the University of Wisconsin Army School for Automobile Mechanics, organizing the work of this department. Since May, 1916, Professor Consoliver has been acting head of the mechanical engineering department, in the absence of B. G. Elliott, retaining, however, his connection with the University Extension Division. On July 1 his title was officially changed to assistant professor of mechanical engineering, University Extension Division, University of Wisconsin.

R. S. Wilbur has assumed the duties of assistant professor of mechanical engineering, Lafayette College, Easton, Pa.

Daniel W. Miller, of the Vacuum Oil Co., Minneapolis, Minn., has recently been made a special representative of the company, with offices at Chicago.

A. O. Gustafson is employed as checker in the engineering department of the Liberty Ordnance Plant, American Can Company, Bridgeport, Conn.

George H. Berge, formerly manager of Murphy Iron Works, Boston office, has succeeded the late M. C. Huyette, of the Buffalo office, and is now district manager for that territory.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

MECHANICAL ENGINEERS for Inspection Division of Ordnance Department; both younger and older men desired. 0603.

MARINE ARCHITECTS, MARINE ENGINEERS, HULL AND ENGINE DRAFTSMEN and other technically trained men for leading shipyards. Several yards are using civil, electrical, and mechanical engineers for construction of hulls or mechinery equipment, and this field of construction offers excellent opportunity for technically trained men. 0597.

FUEL ADMINISTRATION desires volunteers for engineering committees in the following counties in New York State: Wyoming and Orleans, near Buffalo; Livingston, Allegany, Ontario and Wayne, near Rochester; Franklin and Lewis, near Watertown; Herkimer, Otsego and Delaware, near Utica; Hamilton, Greene, Ulster, Sullivan and Orange, near Schenectady; Saratoga, Warren, Essex, Clinton, Washington, Columbia, Dutchess and Putnam, near Albany.

Also a real power-plant engineer to assist in checking up the questionnaires now being sent out. 0659.

FUEL ADMINISTRATION desires volunteers among the older men for office duties, meeting men, handling correspondence, etc. Location, New York office. 0598.

PRODUCTION EXPERTS. Mechanical engineers qualified as production experts for employment in district which extends from the southern portions of Ohio and Indiana to the Gulf of Mexico. Duties are to supervise the production of ordnance work at various plants engaged on Government contracts, and especially to speed up production wherever possible. Applicants should be mechanical engineers of thorough training and broad experience, who have an earning capacity of from $5000 a year upward. Positions require thorough business ability as well as technical knowledge. No one who is engaged directly on Government contracts can be employed. Maximum salary, $3600 per annum. 0658.

TECHNICAL GRADUATE, about 28 years of age, who has had some experience in installing office and shop systems; man who is physically unfit for military service or who has been placed in the limited service; one with initiative and the ability to get results preferred, even if with no previous experience in the work above named. Location Massachusetts. 0586.

ENGINEERS for special investigation work, familiar with general shop practice. Some technical education. Location Government plant on Long Island. 0602.

COST AND TIME-STUDY ENGINEERS, conversant with up-to-date shop methods. Location Government plant on Long Island. 0634.

THE U. S. NAVY GAS ENGINE SCHOOL, Columbia University, is desirous of obtaining names and addresses of men willing to enroll for training for the positions of chief engineer, warrant machinists and chief machinist mates on board the new submarines of the U. S. navy. Applicants must be men who have had extended experience in the operation of Diesel or other heavy-oil engines, and are fully capable of taking charge of Diesel engines, making ordinary repairs, foreseeing trouble, and maintaining the engines in efficient operation. Applicants should be between the ages of 21 and 35, but applications of men up to 40, if exceptionally well qualified, will be considered. The pay is attractive and the several months' training is most advantageous for future work. 0664.

CIVILIAN POSITIONS

FIELD SECRETARY for engineering organization work. Must be able to meet engineers and business men and secure their coöperation. Engineering and executive experience, tact and judgment are essential. Salary $200 to $250 per month, with exceptional opportunity. State draft classification. K. 0604.

HIGH-GRADE FOUNDRYMAN, capable of taking full charge of foundry department with a melting capacity of approximately 150 tons a day; not only a practical foundryman, but one who understands the theoretical side of foundry work, has wide experience in the production of both small and heavy castings, and possesses the necessary executive qualifications to enable him to efficiently supervise actual production work in his department. Location Ohio. J-0604.

INSTRUCTOR IN MECHANICAL ENGINEERING. Position pays a salary of $1600 a year and allows three months' vacation with pay. Work to begin September 15, 1918. Location Louisiana. J-0605.

GRADUATE MECHANICAL ENGINEER for a position leading up to chief engineer. Should have had five to ten years' experience in engineering department of a steel plant. Send résumé of education, experience and salary. Interview will be necessary. Location Pennsylvania. J-0606.

ASSOCIATE PROFESSOR OF MECHANICAL ENGINEERING in an eastern university, to have charge of classes in machine design and allied subjects; teaching and practical experience necessary. Engagement to begin October 1. J-0607.

PRODUCTION ENGINEER to take charge of cost-reduction work in Canadian shop manufacturing air compressors, rock drills and other lines. Gantt system preferred. State age, experience and salary expected. J-0608.

ASSISTANT TO CONSULTING ENGINEER for a large, nationally known manufacturing concern. Young man wanted with college training in mechanical engineering and who is in deferred classification under Selective Service Act. Experience in heating and power-plant engineering desirable. Work directly connected with the war, as company is over 75 per cent. engaged on Government work. Position permanent, with excellent opportunities for advancement. Location New York City. Apply by letter, outlining experience and stating salary expected. J-0609.

YOUNG MEN OF COLLEGE EDUCATION and some ability and training in research work. Experience in particular line not required, but a good measure of common sense and originality will be at a premium. Pay $150 to $200 per month or more for a man of undoubted ability. Headquarters Eastern New Jersey. Apply by letter. J-0610.

SALES ENGINEER of experience for position of sales manager. Must be good executive, thoroughly familiar with modern sales methods and experienced in power-plant and combustion engineering. Location Middle West. J-0611.

TECHNICAL GRADUATES specializing in power-plant and combustion engineering wanted as sales engineers. Must have good address and be either experienced salesmen or prepared to take course of training. Splendid opportunities to men possessing necessary qualifications. Location Middle West. J-0612.

YOUNG MAN to teach the elementary portion of mathematics and physics for the coming year, beginning September 17. Salary $800 to $1,000. College in New York State. J-0613.

STEAM-ENGINE DESIGNER. Man with broad experience in the design of tow-boat and marine engines. Give full details of experience, age and salary. Good opportunity for high-grade man. Apply by letter. Location Pennsylvania. J-0614.

INSTRUCTORS. Salary $1500 or $1600. Location Philadelphia. J-0615.

CHIEF DRAFTSMAN with executive ability, capable designer, competent to supervise ordering of materials and with capacity for details. Experience in general machine design, structural steel and electrical machinery. Salary $300. Location New York City. J-0618.

YOUNG MECHANICAL ENGINEER to do drafting; one with some experience in factory construction work. $35 to $40 a week. Location Newark, N. J. J-0622.

MECHANICAL ENGINEERS. Corporation doing a large percentage of Government work needs services of two engineers, preferably college graduates. In addition to mechanical engineering experience should have experience in scientific-management methods to direct and superintend a department for manufacturing, estimating and general investigation matters. Opportunity for the future is assured. In reply state age, nationality, references and present salary. J-0623.

TECHNICAL CORRESPONDENT. Man if possible not subject to draft, owing to physical reasons or on account of age, capable of taking charge of technical correspondence. Boston concern. J-0624.

INSTRUCTOR IN MECHANICAL ENGINEERING for University of Cincinnati. J-0625.

HIGH-GRADE EMPLOYMENT MANAGER. Man with college education, some employment experience, initiative and aggressive, capable of taking hold of an employment organization and developing it to meet the exacting requirements of the present day; capable of influencing men and women workers by pleasant personality, fairness and ability to get things done on time and in the right way. Salary $200 to $250 per month. State age, education, experience and names of last three employers, with the length of service in each case, as well as responsibility assumed. Appreciate photograph. Address L. W. Wallace, Assistant General Manager, Personal. J-0626.

RATE-SETTING AND TIME-STUDY WORK. Salary $35 to $40 a week, depending entirely on the man. J-0627.

DRAFTSMAN in contractor's office. Must be thoroughly experienced in conveying systems for boiler houses, ground storage plants, locomotive coaling stations, etc., and familiar with structural steel. Permanent position, good salary and opportunity for advancement to right man. State salary desired and complete experience. Apply by letter. Location Philadelphia, Pa. J-0628.

DRAFTSMAN. Competent designer and detailer. Man experienced in stationary boiler and power-plant work. Steady position and good salary. Location New York. Give age, experience, references and military status. J-0629.

INSTRUCTOR IN MECHANICAL ENGINEERING in well-known university in Maryland. College graduate with some experience in machine design and experimental engineering preferred. Salary $1700 or more, depending upon man engaged and the number of courses arranged for him to teach. J-0635.

ESTIMATING AND SALES ENGINEER. Large manufacturing company producing a complete line of mining machinery has opening for graduate mechanical engineer to assist in estimating, ultimately becoming sales engineer. Must be draft-exempt. Reply by letter. J-0636.

DRAFTSMAN—DESIGNER. Man experienced on automatic machinery for large manufacturing plant doing Government work. Permanent position. State age, education, previous experience, salary desired, etc. Location Cleveland, Ohio. J-0637.

MECHANICAL DRAFTSMAN, preferably one with experience in the design of high- or low-pressure air compressors, marine or high-speed engines. Permanent position. Location Connecticut, within 50 miles of New York City. Salary depends on past experience. J-0639.

DRAFTSMEN. Plant-layout men for general lines with knowledge of building construction and equipment. Position in Georgia. J-0640.

ESTIMATING ENGINEER, experienced in the purchasing line. Applicant should have technical training and be competent to estimate cost on construction work and mechanical equipment such as would be involved in the construction of water-filtration plants, both gravity and pressure types. Location New Jersey. J-0642.

CHIEF DRAFTSMAN to take charge of drafting room of about 120 men with company engaged in design and construction of by-product coke ovens, benzol and toluol plants. Prefer man with by-product coke-oven experience, but will consider man from other line of work, provided he has had general mechanical engineering experience and possesses good executive ability. Must be an American. Give full particulars with application; age, previous positions occupied, etc. J-0643.

SUPERINTENDENT OF TOOL ROOM. Will pay $5000 to $6000 a year to the right man, who must be capable of taking charge of toolmakers, getting out jigs and fixtures accurately and in a reasonably quick time. Should be fairly experienced not only in the making of tools and fixtures, but in the design of same. Location Buffalo, N. Y. J-0644.

ENGINEER fully capable and familiar with the design and manufacture of small motors not exceeding 2 hp. J-0645.

DRAFTSMEN on power-plant and industrial-plant design—not electrical men. Work is indirectly Government work, along the lines of fuel conservation in the New England States. Also some Government construction work. Headquarters Connecticut. J-0646.

BOILER-ROOM FOREMAN to take care of 10,000 boiler hp., operate Taylor stokers and take care of compound engines. Salary about $2000. Location Staten Island, N. Y. J-0647.

TECHNICAL GRADUATE with practical experience, preferably including marine experience, to take charge of a night class in steam-engine practice. Write, stating experience. J-0648.

TECHNICAL GRADUATE, with practical experience, to take charge of a night class in gas-engine practice. Write, stating experience. J-0649.

MACHINERY DRAFTSMAN AND ENGINEER capable of figuring stresses in all parts of punching, shearing, plate-planing, bending and rolling machinery. J-0650.

INSTRUCTORS of professional rank in electrical engineering and mechanical engineering, both positions connected with training of men for Army. Prefer men with practical experience and will consider men with no previous experience. Salary $2500 or more for first-class men. Term begins about October 1. J-0651.

MAN to take charge of employment and welfare departments. Ninety per cent. Government work and manufacture of automatic screw tools. $200 to $250 for good man. J-0652.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be on hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

GENERAL OR WORKS MANAGER of a manufacturing concern. Position desired by a successful executive having extensive and exceptional experience with high-grade manufacturing concerns. Any firm needing a man to manage, who has learned how by hard knocks, will be supplied complete record on request. J-238.

STEAM-TURBINE SPECIALIST. Mechanical engineer, American, with 15 years' experience in U. S. and abroad in the designing, calculation, manufacture, testing and operation of small and large steam turbines, desires permanent position. J-239.

FUEL ENGINEER. Graduate mechanical engineer, age 35, with nine years' experience in the scientific testing of coal in all kinds of industrial plants, for one of the largest coal companies in the Middle West, desires position as combustion engineer for a large user of coal doing essential war work. At present employed. J-240.

MANAGER OF MACHINE WORKS OR SHIPBUILDING PLANT. Member, graduate mechanical engineer, wants responsible executive position with right concern. Experienced in progressive management, modern production, and handling and developing men; familiar with ship work and broad class of engineering. All-American, accurate and thorough, with first-class record in both design and construction of special machinery, machine-shop work, structural steel, power plants, piping, transmission and conveying machinery, and air compressors. Salary $7500 to $9000; only best propositions considered. J-241.

MECHANICAL ENGINEER, 1917 technical graduate, exempt from draft, with one year's experience in steam-power plant in construction, operation and maintenance. Some shop and electric railway equipment experience. Location around New York City. J-242.

TECHNICAL GRADUATE. Age 44; fifteen years' practical experience, covering machine shop, drafting room, estimating, cost accounting, rate setting, and modern shop management along production lines. J-243.

EXECUTIVE. Mechanical and production engineer with 25 years' wide, practical experience in developing, maintaining, systemizing and experimenting, and in all kinds of mechanical problems with light, interchangeable, high grade machinery and tool production. J-244.

MANAGER, EXECUTIVE ENGINEER. Mechanical engineer, technical graduate with broad business and engineering experience. Has developed power plant for unit steam railway car and designed vital parts that are now being used on steam automobiles. Splendid in designing and construction. Ample references. J-245.

FOUNDRY SUPERINTENDENT. Member, at present employed as general superintendent of large manufacturing plant, invites correspondence from employers who may need the services of a high-grade foundry executive about December 1. Practical molder, technically trained—steel, gray iron, brass, bronzes, etc. Desires position where mechanical and technical training combined with a broad, practical experience in modern shop methods will afford opportunity to broaden experience gained in several large corporations to better advantage. Excellent references from past and present employers. Married; dependents (3); age 43. Salary not less than $5000. J-246.

ENGINEER open for engagement in manufacturing or executive sales work. Would make excellent assistant to general manager; long experience in manufacture of alternating and direct-current motors, including fractional hp. sizes, and having executive and sales experience. J-247.

EXECUTIVE, SUPERINTENDENT, OR MECHANICAL ENGINEER. American, 38 years of age, married, with a wide experience in chemical plants and general engineering work, covering maintenance and operation of industrial works. Can furnish highest references. Now superintendent of chemical plant on Pacific Coast with salary $4000 per year; will consider making a change if suitable connections can be made. J-248.

ENGINEER, highly trained, with executive experience, desires position as technical adviser or assistant to president or general manager. Engineering degrees from two technical schools and Ph. D. from one of the great American universities. Specially skilled in mathematical physics and its application to the solution of engineering problems. Twenty-five years' experience, covering chemical and testing laboratory work, metallurgical operation, design and execution of heavy construction, water power and industrial investigations, valuation and some electrical operation. Familiar with properties and uses of most engineering materials. Unmarried, physically sound and accustomed to work in emergencies without regard to hours. Reads French and Spanish readily and speaks some Spanish. Last 15 years in consulting practice. Prefers connection with interests developing large enterprise. American-born and of American parentage. Will go anywhere in United States, allied or friendly countries. Salary about $7500. J-249.

MECHANICAL ENGINEER, associate member, desires executive position requiring thorough technical training and experience with ability to handle men and situations. Class 4 of draft. J-250.

MECHANICAL ENGINEER with 15 years' experience as machinist, foreman and tool designer for interchangeable work and steel stampings; high-grade technical and practical executive. Associate member, age 36, married, technical graduate; can develop automatic labor-saving machinery and equip factory for economical quantity production. Desires position as mechanical superintendent with progressive concern. J-251.

MECHANICAL ENGINEER understanding machine and press work desires responsible position with a progressive firm. Experience in office and shop. Successful record as foreman, but desires to advance. M. I. T man, age 28, Class I of draft. Prefer location in Connecticut. J 252.

CHIEF ENGINEER of medium machine building plant wishes to connect with larger concern as assistant works manager or assistant chief engineer, chief draftsman, or any important executive position. Resourceful, rapid designer, with inventive ability; graduate M E.; experience in factory organization and systematizing; not afraid of long hours. $3000 to start. J-253.

MECHANICAL ENGINEER. American, with 12 years' experience covering shop, time study, erection, design, sales and general office. Age 35, married, technical graduate. Employed at present. Desires position in engineering executive line with responsibility. Relations with co-workers invariably pleasant and successful. Exemplary habits and good health. Can report promptly. J 254.

MECHANICAL ELECTRICAL ENGINEER with wide experience in internal combustion engine foundry and machine-shop practice and exceptional executive ability. Now at the head of a very large concern. Speaks English, French and Italian fluently. Available within a reasonable time. Minimum salary $1800. J 255.

SUPERINTENDENT OR WORKS MANAGER. American, age 43, with 22 years' practical experience with large organizations and modern methods of operation in the production of automatic, semi-automatic and single purpose machines, also the economical manufacture of interchangeable parts from small ball bearings to large machine tools. By the proper use of a good technical education, ability to handle all classes of help, combined with tact and common sense, have been able to successfully fill positions of machinist apprentice, toolmaker, general foreman, chief draftsman, superintendent and works manager. Two years in charge of 600 men on munitions and screw-machine products. Eastern location preferred. J-256.

MECHANICAL-ELECTRICAL ENGINEER. Designer and inventor of heavy motor control devices in general use, who is employed, but inactive on account of war conditions, desires active employment in development work in which experience and ingenuity are essential. Special consideration will be given to openings likely to prove permanent. Graduate of leading technical college, fully conversant with manufacturing; member A. S. M. E., associate member A. I. E. E. J-257.

WORKS MANAGER OR SUPERINTENDENT Position desired by member successful in general manufacturing lines and with broad experience as executive in plants with foundry, pattern, polishing, plating and machine-tool departments. Thoroughly familiar with cost accounting, estimating, stock control and general office routine. Will be available early in October. J-258.

DIESEL ENGINEER with experience on stationary and marine engines desires position in this capacity, preferably with a concern engaged in Government work. Draft class 4. J-259.

ENGINEER with broad designing and production experience and six years in charge of design work desires position as engineer or chief draftsman. J-260.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER OCTOBER 21

BELOW is a list of candidates who have filed applications since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of applications 161.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by October 21, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

CUMMINGS, E. P., Operating Superintendent, Alabama Power Co., Birmingham
MUELLER, Grover R., Manufacturers' Agent and Sales Engineer, Birmingham

California

BOWEN, Samuel R., Manager, Oil Tool Dept., S. A. Guiberson, Los Angeles
DRAKE, Frank B., President and Manager, Johnson Gear Co., San Francisco
GRUNDEL, Irving G., Draftsman, Union Oil Co., Oelum
IRELAND, Thomas W., Engineer, Steam Heat Dept., Great Western Power Co., San Francisco

Colorado

PERSON, Howard A., Chief Engineer, United Oil Co., Florence
WILLIAMSON, Edward L., President and Manager, West Riverside Canal Co., Riverside

Connecticut

MORELAND, Albert S., General Foreman, Remington Arms Co., Bridgeport
RHEAUME, Herman C., Plant Engineer, Stamford Rolling Mills Co., Stamford
SMITH, Charles F., Engineer, Remington Arms Manufacturing Co., Bridgeport
TAPPAN, Dewitt, Assistant Superintendent, Veeder Manufacturing Co., Hartford

District of Columbia

BYRNE, Henry H., Aeronautical and Ordnance Patent Expert, War Department, Washington
ETTENGER, Robert L., Consulting Mechanical Engineer, Southern Railway System, Washington
LOWE, James R., Mechanical Engineer, Ordnance Department, Engineering Division, Washington
SNELLING, Henry H., Engineer and Expert, Church and Church, Washington

Illinois

CHRISTOPHERSEN, C. Birger, Engineering Draftsman, Illinois Steel Co., So. Chicago
McFARLAND, Owen D., Mechanical Engineer, Gayton & Cumfer Mfg. Co., Chicago
MERRICK, Wendell S., Captain, 309th Engrs., 84th Div., U. S. A., Chicago
REECE, Wade W., Chief Engineer, Schulze Baking Company, Chicago

Indiana

HUTCHCRAFT, D. K., Vice President Indiana Air Pump Co., Indianapolis

Iowa

SAENGER, Louis P., General Superintendent, Mechanical Engineer, Clinton Sugar Refining Co., Clinton

Maryland

RACH, J. Louis W., Superintendent and Mechanical Engineer, E. J. Codd Co., Baltimore

Massachusetts

MAHON, Thomas, Foreman Machinist, Becker Milling Co., Hyde Park
RANGER, James A., General Contractor, Holyoke
SHEAK, Edwin R., charge of all mechanical operations, Thomas G. Plant Co., Roxbury

Michigan

EATON, Homer M., General Manager of Gas Companies operated by W. E. Moss & Co., Detroit
GARLAND, Harrison W., President The M. Garland Co., Bay City
KETTLE, Edgar U., Consulting and Research Engineer, Grand Rapids Veneer Works, Grand Rapids
KIEFER, Edgar W., First Vice President, Port Huron Sulphite & Paper Co., Port Huron
STANBROUGH, Duncan G., General Superintendent, Packard Motor Car Co., Detroit
WILSON, Charles B., President and General Manager, Wilson Foundry & Machine Co., Pontiac

Minnesota

MORRIS, John E., Secretary and Treasurer, Stacy-Bates Co., Minneapolis

Nebraska

ANDERSON, Augustus C., Consulting Engineer, Anderson and Bennett, Omaha

Nevada

LITTLE, Robert E., Chief Draftsman and Assistant to Master Mechanic, Los Angeles & Salt Lake R. R., Las Vegas

New Jersey

HORNING, Maurice O., Engineer, American Gas Furnace Co., Elizabeth
RUSSEN, Frank A., Chief Patternmaker, Safety Car Heating & Lighting Co., Jersey City

TALMAGE, Walter H., Mechanical Engineer, The Heller & Merz Co., Newark
TOLFAIR, William D., Product Engineer, Laboratories of T. A. Edison, West Orange
VAN AKEN, Lionel D., Lt. Colonel, Ordnance Department, Production Officer, E. I. du Pont de Nemours & Co., Pompton Lakes

New York

BURMISTROFF, Ivan, Assistant to Engineer, Russian Mission of Ways of Communication, New York
COHEN, Frederick W., Assistant General Manager, Metal & Thermit Corporation, New York
CRANK, Albert F., Secretary, Acting Treasurer, Chief Engineer, Conveying Weigher Co., New York
GRIFFIN, W. A., Captain, Ordnance Department, U. S. A., Assistant Production Manager, Rochester Ordnance Office, Frontier Iron Works, Rochester
HAMMOND, Edward K., Associate Editor of "Machinery," New York
JAMIESON, Charles M., Operating Planner, Wright-Martin Aircraft Corp., Long Island City
KINNEY, Price W., Employment Manager, Gleason Works, Rochester
LECHLER, Bruno C., General Manager, S. S. Hepworth Co., New York
LEVIN, Vladimir Z., Chief Inspector, Russian Mission of Ways of Communication, New York
LOOMIS, Crawford Charles, Engineer, Remington Arms U. M. C. Co., Inc., Ilion
LOWE, Aubrey L., Assistant Superintendent, Remington Arms U. M. C. Co., Inc., Ilion
REDIER, Roger P., General Sales Manager, Allied Machinery Co. of Am. New York
UPTEGRAFF, Thos M., Secretary and Manager, Defiance Paper Co., Niagara Falls
VAN GELDER, George S., 1st Lieut., Ordnance Department, U. S. A., New York
WEBB, Daniel J. H., Superintendent and Mechanical Engineer, Franklin Contracting Co., New York
WIKANDER, Oscar R., Consulting Engineer, S. K. F. Administration Co., New York
WILSON, James A., Engineer, Corning Glass Works, Corning

Ohio

BLITZ, Edgar G., Time Study and Efficiency Engineer, Toledo Scale Co., Toledo
FAUZON, Arturo, Mechanical Engineer, The World's Products Research Co., Cleveland
GREEN, Carl R., Manager and Owner, Green Engineering Co., Dayton
McCORMACK, Daniel J., Hydraulic Engineer, The Wellman Seaver Morgan Co., Cleveland
NONNEMAN, I. W., Chief Engineer, the Borden Co., Warren
SAUZEDDE, Claude, Manufacturing Engineer, Steel Products Co., Cleveland
SCHOENBERGER, John H., Draftsman and Designer, The Lunkenheimer Co., Cincinnati
STOLBERG, Charles A., Major, Ordnance Department, U. S. A., Maxwell Motor Co., Dayton
WALTZ, Burt A., Department Planning Engineer, The B. F. Goodrich Co., Akron
WEAVER, Thomas D., Chief Engineer, Humphryes Mfg. Co., Mansfield

Oklahoma

CRAIG, Clyde B., Manager, Mid-West Branch, Bessemer Gas Engine Co., Tulsa

Oregon

KINCAID, Morden F., Mechanical Valuation Engineer, Spokane, Portland & Seattle Ry., Portland

Pennsylvania

AYARS, Allan M., Efficiency Engineer, Landis Tool Co., Waynesboro
BURDICK, Frederick H., Member of Firm, Standard Engineering Co., Pittsburgh
BUSH, Paul H., Assistant and Chief Draftsman, Frankford Arsenal Tool Division, Frankford Arsenal
COLEMAN, Harry S., Assistant Director, Mellon Institute of Industrial Research, Pittsburgh
ELLIS, Roy M., Manager, A. H. Fox Gun Co., Philadelphia
HEARSEY, Winthrop O., Superintendent of Machine Shop No. 5, Bethlehem Steel Co., Bethlehem
HILTEBEITEL, M. M., Power Apparatus Engineer, Westinghouse Elec. & Mfg. Co., Philadelphia
McDOWELL, Elmer K., Chief Works Engineer, Donora Steel Works, Donora
MEISENHELTER, Lewis R., Proprietor and Owner, L. R. Meisenhelter Machinery Co., Philadelphia
MENISH, John R., Chief Mechanical Engineer, Pennsylvania Lubricatng Co., Pittsburgh
NEWHALL, Ezra A., Designer and Draftsman, Rolling Mill Machinery, R. S. Newbold & Son Co., Norristown
RYAN, John Thomas, Vice President and General Manager, Mine Safety Appliances Co., Pittsburgh
SHARP, Robert E. B., Assistant Hydraulic Engineer, I. P. Morris Department, William Cramp & Sons Ship Engine Bldg. Co., Philadelphia
SHEARER, Harry T., President, General Manager, H. T. Shearer Machine Co., Waynesboro
SLEICHER, Charles A., President, Queen's Run Fire Brick Co., Lock Haven
TERHUNE, Howard, Designer and Assistant Sales Manager, Chambersburg Engrg. Co., Chambersburg
WEGMAN, Leroy A., Aeronautical Mechanical Engineer, Naval Aircraft Factory, Navy Yard, Philadelphia

Rhode Island

JENCKES, Robert A., Department Manager, General Fire Extinguisher Co., Providence

South Carolina

MAYO, James B., Engineer and Inspector, Factory Insurance Association, Greenville

Tennessee

HOLT, Herbert F., Consulting and Contracting Engineer Practice. Knoxville

Virginia

MOSS, William D., Manager, Capitol Motor Corp., Richmond

Wisconsin

HUEYLER, William, Mechanical Appraiser, The American Appraisal Co., Milwaukee

Canal Zone

MORRIS, Thomas C., Assistant Engineer, Panama Canal, Balboa Heights

France

INGLIS, Henry B., Aviator in United States Service. American Expeditionary Forces

Java

KNEPPERS, Jos. M., Engineer, Harrisons & Crosfield, Ltd., Batavia

Mexico

ARIZPE, Emilio, Manager, Aurora Cotton Spinning & Weaving Mill, Saltillo, Coah.

South America

WHEELER, Burr, Resident Engineer, Chile Exploration Co., Tocopilla, Chile

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE MEMBER

District of Columbia

ADAMS, Ralph L., First Lieutenant Engineering Division, Motor Transport Corps, Washington

Illinois

CROWDER, Carl G., Production Engineer, Western Electric Co., Inc., Chicago

Maryland

BIMESTEFER, John, Jr., Designing Draftsman, Bethlehem Steel Co., Sparrows' Point

Massachusetts

SMITH, Robert L., Mechanical Engineer, Baxter D. Whitney & Son Winchendon

New Jersey

DAVIS, Frederick H., Mechanical Engineer, Balbach Smelting & Refining Company, Newark

New York

ARNTZEN, Asbjorn, Assistant Mechanical Engineer, F. L. Smith & Co., New York

Ohio

DAVIS, Howaad E., Mechanical Superintendent, The Austin Co., Cleveland
WALTERS, Carl F., Chief Engineer, Safe Cabinet Co., Marietta

Pennsylvania

BUDD, Alfred N., First Lieutenant, Ordnance R. C., Army Ins. of Ord., Hero Mfg. Company, Philadelphia

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Delaware

ARMOR, Robert B., Chief Engineer, Benjamin F. Shaw Company, Wilmington

District of Columbia

VAN KEUREN, Harold L., Chief of Gage Section, Bureau of Standards, Washington

Illinois

BRAUNBERGER, Ray A., Sales and Industrial Engineerng, R. E. Ellis Engrg. Co., Chicago
TIKALSKY, Francis P., Section Head in machine and analysis Department of Planning Division, Western Electric Co., Inc., Hawthorne

Iowa

OGDEN, Frank F., 2nd, Consulting, Designing and Supervising Engineer and Architect, Expert Draftsman, Eddyville

Massachusetts

JOHNSON, Robert A., President and Manager, Franklin Machine and Tool Co., Springfield

Michigan

FISK, Louis C., Assistant Engineer, Motor Division, Hyatt Roller Bearing Co., Detroit
KERSHAW, Adolphus L., First Lieutenant, Ordnance Department, U. S. A., Eng. Div., Motor Equipment Section, Maxwell Motor Co., Detroit
TURNER, Edwin N., General Manager, Manistee Iron Works Co., Manistee

Minnesota

ROMERO, Cirilo, Instructor in Marine Steam Engineering at the U. S. Navy Training School, University of Minnesota, Minneapolis

New Jersey

KESHEN, Charles G., Assistant Managing Engineer, Hoist Department, Sprague Electric Co., Bloomfield

New York

ANDERSON, George B., Jr., General Representative of Selling Agent, N. Y. & N. E. Districts, Pittsburgh Valve, Foundry & Construction Co., New York
BROOK, Victor, Publicity Engineer with title of "Field Service Manager," New York

CHATEL, Fred J., Ensign, U. S. N. R. F. U. S. S. "Huntington," New York
FRIEDMAN, Jno. H., Captain, Assistant Superintendent of Shops, Watervliet Arsenal, Watervliet
HYATT, John E., U. S. Naval Reserve Officers' Material School, Scarsdale
JACOBS, Loring H., U. S. Navy, Bureau of Construction and Repair, Avation Section, care Superintending Constructor of Aircraft, Buffalo
JARECKIE, Eugene A., Assistant Engineer of Honolulu Iron Works Co., New York
PARSONS, Loren E., Design Engineer, Western Electric Co., Inc., New York

Ohio

HARLAN, Jesse R., Sales Engineer, The Stuebing Truck Company, Cincinnati

Oklahoma

TABER, George H., Jr., General Manager, Gasoline Department, Sinclair Oil & Gas Company, Tulsa

Pennsylvania

STEVENS, Harold G., Captain, Ordnance Department, U. S. A., Superintendent Artillery Assembling Shops, Frankford Arsenal, Philadelphia
WHITAKER, John C., Production Engineer, Midvale Steel & Ordnance Co., Nicetown, Philadelphia

Canada

CHESNEY, Andrew M., Assistant Works Manager, Canadian Explosives Co., Limited, Beloeil Station, Quebec

France

KURTZ, Walter H., Senior Master Mechanic Engineer, 49th U. S. Engineers, American Expeditionary Forces

South America

WRENCH, Robert A., Assistant to Chief Electrical Engineer, Braden Copper Company, Rancagua, Chile

FOR CONSIDERATION AS JUNIOR

Arizona

HANSON, Ray, Apprentice Instructor and Mechanical Clerk, S. P. Shops, Tucson

California

PILLARS, Harry M., Chief Draftsman, Jos. Wagner Mfg. Co., San Francisco

Connecticut

BUXBY, Paul M., First Lieutenant, Ordnance Department, U. S. A., Remington Arms U. M. C. Co., Bridgeport

Delaware

KUO, Cheng C., Ship Building, Harlan & Holingsworth Corp., Wilmington

District of Columbia

OAKES, Charles E., Associate Electrical Engineer, Bureau of Standards, Washington

Illinois

ALLEN, Harold F., Mechanical Engineer, Link Belt Co., Chicago

Maryland

MOORE, Walter E. J., Chemical Warfare Section, Edgewood Arsenal, Edgewood

Massachusetts

ALEXANDER, Harold C., Machine Designer, The Lapointe Machine Tool Co., Hudson
DUNCAN, Joseph B., Industrial Engineer, New England Westinghouse Co., Chicopee Falls
LENK, David A., District Gauge Supervisor, Gauge Section, Insp. Division, Ordnance Department, U. S. A., Boston
WILLIAMS, Fred C., Jr., Assistant to Mechanical Engineer, The Fiberloid Corp., Indian Orchard

Michigan

CULVER, Edward P., Second Lieutenant, Air Service Aeronautics, U. S. A., Instrument Officer, Mt. Clemens
GILLIARD, Pierre G., Chief Engineer and Factory Manager, Michigan Wheel Co., Grand Rapids
HERBERT, Robert H., Inspector of Naval Gun Mounts, Linderman Steel Mach. Co., Muskegon

New Hampshire

NEWTON, Wilbur F., Marine Draftsman, Portsmouth Navy Yard, Portsmouth

New Jersey

GROB, John J., Construction Engineer for Main Power House, H. & M. R. R., Jersey City

New York

BIDERMANN, Frederick A., Junior Engineer, Bureau of Engineering, New York
CRAIG, Thomas H., Jr., Salesman, Manning, Maxwell & Moore, Inc. New York
FOX, Samuel M., Ensign, U. S. Naval Reserve Force, Aeroplane Inspection, Buffalo
GIES, Claude T., Mechanical Designer, Otis Elevator Co., New York
GUTHRIE, Robert G., Engineer, Laboratory of the Curtiss Aero Corporation. Buffalo
KOSWICK, Alexander A., Assistant to Buyer of Fabricated and Special Tools, Wright, Martin Aircraft Corp., New York

North Carolina

SHERRILL, Sloan S., Mechanical Engineer, Chemical Construction Co., Charlotte

Pennsylvania

BROWN, Charles H., Jr., Supervisor of Electric Machinery and Lines, Atlantic Refining Co., Philadelphia
DUDA, Wentzel R., Designer, United Engineering and Foundry Co., Pittsburgh
FAGERSTROM, Otto, Draftsman, Carnegie Steel Co., Duquesne

South Carolina

BLACKWELDER, Charles D., Assistant Chief Mechanical Engineer, American Machine & Manufacturing Co., Greenville

Texas

GRAEF, Louis F., Draftsman, American Smelting & Refining Co., El Paso

Vermont

KEATOR, Simon P., Cost Engineer, Vermont Farm Mach. Co., Bellows Falls

Virginia

WIDELL, Berndt A., Jr., Assistant Engineer, Coast Artillery Corps, Fifth Training Co., Fort Monroe

CHANGE OF GRADING

PROMOTION FROM JUNIOR

Minnesota

HANSON, John J., First Lieutenant, Ordnance R. C., Inspection Section, Carriage Division, Minneapolis Steel & Machinery Co., Minneapolis

New York

FRITZ, Aime L. G., Superintendent of Construction, H. R. Kent & Co., New York
ROMAN, Henry, in Charge of the Designing of Liquid Air Plants, Air Nitrates Corp., New York

Pennsylvania

LAMOREE, James K., Mechanical Engineer, American Sheet & Tin Plate Co., Shenango Works, Newcastle

Rhode Island

BROWN, Wendall S., Industrial Engineer, F. P. Sheldon & Sons, Providence

PROMOTION FROM ASSOCIATE MEMBER

Connecticut

JENNINGS, Irving C., Vice President and General Manager, Chief Engineer, Nash Engineering Co., South Norwalk

Missouri

MacKINNON, James A., Superintendent of Forge Shop, Scullin Steel Co., St. Louis

New York

HUBBARD, Frank B., Plant Engineer, Pierce Arrow Motor Car Co., Buffalo
MOORE, William J., Consulting Engineer, Inter-Continental Machinery Corp., New York

SELECTED TITLES OF ENGINEERING ARTICLES

THE section Selected Titles of Engineering Articles comprises an index to current articles on mechanical engineering and related subjects.

This work has been made possible by the remarkable collection of current technical periodicals available in the Library of the United Engineering Society, which is one of the greatest and most complete collections in the world. The Library receives, even now, when some of the foreign periodicals have ceased to come to its shelves, close to a thousand different papers, magazines and transactions of societies in the engineering and scientific fields, in not less than ten languages. The Society's engineering staff examines these publications as they are received and prepares the cards which are ultimately used in the Selected Titles section of THE JOURNAL.

Chief attention is paid to articles directly concerned with the branches of mechanical engineering. When it is thought they will be of interest or value to mechanical engineers, however, other articles are listed, in the realms of physics and chemistry; civil, mining and electrical engineering, technology, etc.; and in subjects in broadly related fields such as training and education, safety engineering, fire protection, employment of labor, welfare work, housing, cost keeping, patent law, public relations, etc. Cross-references are introduced and where the titles themselves are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PERIODICAL SHELVES, LIBRARY OF UNITED ENGINEERING SOCIETY, NEW YORK

Over 1000 periodicals are regularly received by this library from all parts of the world. These are examined and indexed each month by the staff of The American Society of Mechanical Engineers in the preparation of the Selected Titles Section of THE JOURNAL.

PHOTOSTATIC PRINTS

Photostatic copies may be obtained of any of the articles listed in this section.

Price of each print (up to 11 x 14 in. in size), 25 cents, plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Orders should be sent to

HARRISON W. CRAVER, *Director,*
Engineering Societies Library,
29 West Thirty-ninth Street,
New York

AERONAUTICS

Aerostatics

Military Aerostatics. H. K. Black. Aerial Age, vol. 7, nos. 22 and 23, Aug. 12 and 19, 1918, p. 1064, 1 fig., pp. 1118-1119, 1 fig. (Aug. 12). Features of the Cacquot observation balloon; (Aug. 19). Action of automatic valve. (Continuation of a serial.)

Altitudes

The Flight of an Aeroplane at Different Altitudes. L. de Bazillac. (Translated from original French by B. Bruce Walker). Flight, vol. 10, nos. 28 and 29, July 11 and July 18, 1918, pp. 779-781, 4 figs., and pp. 811-813, 3 figs. (July 11). Equations involved in the study of two ways of flying the aeroplane under the thrust of contact: 1, at constant speed and increasing altitude, the engine running normally all the time; 2 keeping altitude constant by reducing speed of engine in proportion in which the oil and petrol are consumed. (July 18). Curves and formulæ; resistances per unit weight in terms of angle of attack. (Continuation of serial.)

Engine Pistons

Report on Aluminum Pistons from 230 HP Benz Engines. Aeronautics, vol. 15, no.

NOTE.—The abbreviations used in indexing are as follows: Academy (Acad.); And (&); American (Am.); Associated (Assoc.); Association (Assn.); Bulletin (Bul.); Bureau (Bur.); Canadian (Can.); Chemical or Chemistry (Chem.); Electrical or Electric (Elec.); Electrician (Elecn.); Engineer [s] (Engr. [s]); Engineering (Eng.); Gazette (Gaz.); General (Gen.); Geological (Geol.); Heating (Heat.); Industrial (Indus.); Institute (Inst.); Institution (Instn.); International (Int.); Journal (Jl.); London (Lond.); Machinery (Machy.); Machinist (Mach.); Magazine (Mag.); Marine (Mar.); Materials (Matls); Mechanical (Mech.); Mining (Min.); Municipal (Mun.); National (Nat.); New England (N. E.); New York (N.Y.); Record (Rec.); Refrigerating or Refrigeration (Refrig.); Review (Rev.); Railway (Ry.); Scientific or Science (Sci.); Society (Soc.); United States (U. S.); Ventilating (Vent.); Western (West.); State names (Ill., Minn., etc.); Proceedings (Proc.); Transactions (Trans.); Supplement (Supp.).

247, July 10, 1918, pp. 46-48, 4 figs. Details of design and result of a metallurgical analysis of the composition of the alloy carried out by R.A.E. Engine was taken from the Aviatik biplane G.130, captured Feb. 12, 1918. Issued by Technical Dept., Aircraft Production, Ministry of Munitions. Account also published in Flight, vol. 10, no. 27, July 4, 1918, pp. 744-745, 4 figs. Automotive Industries, vol 39, no 9, Aug. 29, 1918, p. 361, 2 figs.; Aviation, vol. 5, no. 2, Aug. 15, 1918, p. 93, 1 fig.; Engineering, vol 106, no. 2740, July 5, 1918, p. 18, 4 figs.

Engine Temperature Control

Making the Aviation Engine Fit for Any Altitude. Sci. Am., vol. 119, no. 6, Aug. 10, 1918, p. 109. Automatic temperature control used in Sturtevant engine.

Engines

The 180 hp. Mercedes Aero-Engine. Aviation, vol. 5, no. 2, Aug. 15, 1918, pp. 98-101, 10 figs. Report on design of engine issued by the Technical Department, Aircraft Production, British Ministry of Munitions.

The Design of Aeroplane Engines, John Wallace. Aeronautics, vol. 15, nos. 247 and 248, July 10 and July 17, 1918, pp. 44-46, 5 figs., and pp. 59-61, 3 figs. (July 10), Air and water cooling of the cylinders; indicator diagram; compression ratio; mean effective pressure; (July 17), power; construction of theoretical indicator diagram; comparison of results. (Continuation of serial.)

Individual Types

Report on the Friedrichshaffen Bomber. Flight, vol. 10, nos. 27, 28 and 29, July 4, 11 and 18, 1918, pp. 737-741, 770-773, 41 figs., and pp. 793-796, 15 figs. F.D.H. G.3 brought down by anti-aircraft fire at Isbergues on Feb. 16. Construction of wings, struts, ailerons, fin and fixed tailplanes; elevators, rudders, bracing, fuselage, engines, radiators, oil pump, petrol tanks, pipings, and propeller. Issued by Tech. Dept., Aircraft Production, Ministry of Munitions. (July 18), Controls; landing gear; instruments; bombs and bomb gear; fabric. (Concluded.)

Some War-Time French Airplanes and Hydroplanes. Automotive Eng., vol. 3, no. 7, Aug. 1918, pp. 304-309, 5 figs. Details of the machine design and construction, also their machine-gun and other equipment. Type of motor mostly used. Some well-known fighting planes of widely varying types. (Second of series.)

The L.V.G. Biplane Type C.V. (Translation from L'Aérophile). Aerial Age, pp. 1122-1123. Comparative specifications of L.V.G. biplanes C.II, C.IV, C.V, and Rumpler C.IV.

The Roland Single-Seater Chaser, D II. Flight, vol. 10, no. 28, July 11, 1918, pp. 765-767, 8 figs. Dimensions, construction of fuselage, form of planes, shape of tail, and armament. (Translated from L'Aérophile.) Also published in Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, pp. 267-268, 2 figs. Mechanical details of fast machine of light construction; fuselage built of plywood covered with fabric.

The S.E. 5A Single Seater Fighter. Automotive Industries, vol. 39, no. 8, Aug. 22, 1918, pp. 315-317, 2 figs. Mechanical details of British machine adopted by U. S. Army authorities; weighs 1554 lb. without load and is equipped with 200 hp. Hispano engine.

Instruments

Navigation Instruments of Our Aerial Pilots. Sci. Am., vol. 119, no. 7, Aug. 17, 1918, pp. 141-142. Tachometer, air speed indicator, altimeter, airplane compass, airplane clocks, pressure gages, radiator thermometer, banking indicator and Aldis sight.

Italian Air Service

Plans and Accomplishments of the Italian Air Service. Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, pp. 272-276, 13 figs. Types of machines that have been developed.

Metal Fittings

Strut Sockets and Other Sheet-Metal Airplane Fittings, Fred H. Colvin. Am. Mach., vol. 49, no. 6, Aug. 8, 1918, pp. 253-256, 15 figs. Illustrated description of making of built-up combinations of sheet-metal stampings and of forgings and stampings.

Model Aeroplanes

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 7, no. 22, Aug. 12, 1918, 1 fig. Drawing giving size and dimensions. (To be continued.)

Model Aeroplanes, F. J. Camm. Aeronautics, vol 15, no. 248, July 17, 1918, p. 68. Study of problem of maintaining coincidence of centers of pressure and gravity in aeroplane flying. (To be continued.)

Mufflers

Exhaust Headers and Mufflers for Airplane Engines, Archibald Black. Gas Eng., vol. 20, no. 9, Sept., 1918, pp. 429-436, 14 figs. Types that have been used and are being used; figures from tests of loss due to muffler; list of references to other literature. Also published in Automotive Industries, vol. 39, no. 4, July 25, 1918, pp. 145-157, 15 figs. Paper presented before S.A.E.

Propellers

Notes on Airscrew Analysis, M. A. S. Riach. Aeronautics, vol. 15, no. 247, July 10, 1918, pp. 41-42, 2 figs. Modifications introduced into the original theory, outlined in The Screw Propeller in Air, Proc. Aero. Soc., Mar. 21, 1917, in order to take account, in a quantitative manner, of the conception of a rotation set up in the fluid both before and behind the actuator disk. (Continuation of serial.)

Predicting Strength and Efficiency of Airplane Propellers, F. W. Caldwell. Automotive Industries, vol. 39, no. 4, July 25, 1918, pp. 152-155. Formulæ and curves; Conventional design compared to adjustable-pitch propeller; efficiency under climbing conditions; comparison of climbing rates; engine with constant torque. (Concluded.) Also published in Aerial Age, vol. 7, no. 21, Aug. 5, 1918, pp. 1011-1018, 14 figs.

The Efficiency of an Airscrew, M. A. S. Riach. Aeronautics, vol. 15, no. 247, July 10, 1918, pp. 38-39. Examination of the quantities in the formula for the efficiency of any blade element, $N^1_x = \tan A/\tan (A^1 + \gamma^1)$ derived in "The Screw Propeller in Air," Proc. Aero. Soc., Mar. 21, 1907.

Wooden Wings for the Modern Mercury. Motor Boating, vol. 22, no. 2, Aug. 1918, pp. 22-23. Various processes employed by the French in the manufacture of propellers for their airplanes.

Royal Aircraft Factory

Products of the Royal Aircraft Factory. Automotive Industries, vol. 39, no. 6, Aug. 8, 1918, pp. 236-238, 12 figs. Models of planes developed by British Government. Further development work left to private concerns.

Standards

International Aircraft Standards. Aeronautics, vol. 15, no. 248, July 17, 1918, pp. 66-67. Specifications for aeroplane spar varnish; specifications for mercerized cotton aeroplane fabric. (Continued.)

Steel Tubes

Steel Tubes Manipulation and Tubular Structures for Aircraft, W. W. Hackett and A. G. Hackett. Automotive Eng., vol. 3, no. 7, Aug. 1918, pp. 315-318. Front forks for cycles; tapered tubes; tubular liners or reinforcements; tube manipulation; tubular joints in aircraft construction; soft-soldered joints; tests on soldered joints; brazing; silver-soldering; welding. (Second of series.)

Wing Fabrics

Cotton Airplane Fabric, S. Wakefield. Textile World Jl., vol. 54, no. 7, Aug. 17, 1918, pp. 37-39, 1 fig. Construction of yarn and cloth for standard specifications.

Wing Ribs

A New Method for the Testing of Airplane Wing Ribs, I. H. Cowdrey. Automotive Industries, vol. 39, no. 4, July 25, 1918, pp. 140-144, 5 figs. Shows how load application and distribution are controlled by a series of rubber bands, and describes apparatus employed.

See also Machine Tools (Propeller-Shaping Machine); Military Engineering (Anti-Aircraft Firing); Testing and Measurements (Balloon Fabrics).

AIR MACHINERY

Lubrication

Lubrication of Air Compressor Cylinders, W. H. Callan. Power, vol. 48, no. 7, Aug. 13, 1918, pp. 229-230. Résumé of experience showing that a light mineral oil is the lubricant to use.

Soot Blowers

Soot Blowers for Vertical and Hollow Stay-Bolt Boilers. Power, vol. 48, no. 7, Aug. 13, 1918, pp. 222-228, 21 figs. Details of various systems employed; protection for blower elements in high-temperature zones; blowers for hollow-staybolt boilers; continuous ash removal.

Tire Pumps

Official Test of Tire Pumps. Automotive Industries, vol. 39, no. 6, Aug. 8, 1918, p. 243, 1 fig. Curve showing r.p.m. of pump against seconds required to inflate tire, drawn from results obtained at laboratory of Automobile Club of America, New York, with the Cassco power tire pump.

Turbo Compressors

Turbo Air Compressor at the Holbrook Colliery. Engineer, vol. 126, no. 3267, Aug. 9, 1918, pp. 113-115, 7 figs. A 750-hp., 2-stage, reciprocating air compressor driven through helical gearing by a mixed-pressure turbine. Description of unit and its auxiliaries.

Ventilating Fan

New Ventilating Fan at Hardwick Collieries. Iron & Coal Trades Rev., vol. 97, no. 2630, July 26, 1918, p. 91, 1 fig. A 15-ft. fan replaced by smaller one of the multi-blade type.

See also Mines and Mining (Sprayers).

BRICK AND CLAY

Canadian Clay

Report of the Clay Resources of Southern Saskatchewan, N. B. Davis. Can. Department of Mines, no. 468, 1918, 93 pp., 21 figs. Report based on field work and laboratory tests, containing information regarding geological position, locality, and availability of each deposit, and behavior of samples tested in laboratories.

Clay Burning

Burning Clay Wares, Ellis Lovejoy. Clay-Worker, vol. 70, no. 2, Aug. 1918, pp. 128-130. Machine handling and setting; open-top continuous kilns. (Continuation of serial.)

Fire Brick—the Age of Clay Products. Brick & Clay Rec., vol. 53, no. 5, Aug. 27, 1918, pp. 369-371. How two plants in Pennsylvania are turning out their product.

See also Pipe (Clay Pipe).

BRIDGES

Concrete Bridges

Canadian Pacific Railway Viaducts at Toronto. Can. Engr., vol. 35, no. 6, Aug. 8, 1918, pp. 123-124. How it was possible to build two reinforced-concrete bridges 386 ft. long and 90 ft. high, having spans of 35 ft.

Concrete Highway Bridge Design. Surveyor, vol. 54, no. 138, July 5, 1918, p. 8. Ontario Highway Department's specifications.

Rebuilding the C. B. & Q. R. R. Bridge Over the Platte River, Near Grand Island, Neb. Ry. Rev., vol. 63, no. 4, July 27, 1918, pp. 117-120, 10 figs. Reinforced-concrete slabs on concrete piers with reinforced-concrete pile foundation.

Steel Bridges

Bridge Across the River Vistula at Warsaw. Engineer, vol. 126, no. 3265, July 26, 1918, pp. 80-81, 5 figs. Description of 504-meter bridge completed at outbreak of war.

Four-Span Steel Bridge Over the Nicolet River. Contract Rec., vol. 32, no. 27, July 3, 1918, pp. 519-520. Dimensions and brief account of erection.

The Economics of Steel Arch Bridges, T. K. Thomson, C. E. Fowler, W. B. Farr and H. P. Van Cleve. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 843-870, 9 figs. Study and classification of 100 structures. Discussion of J. A. Waddell's paper. (Concluded.)

The Hell Gate Arch Bridge and Approaches of the New York Connecting Railroad Over the East River in New York City, C. E. Chase and O. H. Ammann. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 759-766. Discussion of O. H. Ammann's paper.

Stresses

Why Do Some Bridges Stand Up? E. H. Darling. Contract Rec., vol. 32, no. 34, Aug. 21, 1918, pp. 655-656, 2 figs. Table of estimated stresses under various conditions.

Truss Spans and Towers

New Bridge on the B. & L. E. a Notable Structure. Ry. Age, vol. 65, no. 8, Aug. 23, 1918, pp. 345-351, 16 figs. Continuous trusses and unique construction methods noted.

Oregon-Washington Railroad and Navigation Company's Portland Bridge. Ry. Gaz., vol. 29, no. 2, July 12, 1918, pp. 46-50, 3 figs. Structure and substructure details of the three riveted truss spans and of the two towers between which the central span is lifted vertically.

Wilson Bridge

Wilson Bridge, Over the Rhone, at Lyon (Le pont Wilson, sur le Rhone, à Lyon), A.

Dumas. Génie Civil, vol. 73, no. 2, July 13, 1918, pp. 21-28, 15 figs. Details of construction, sections and dimensions.

BUILDING AND CONSTRUCTION

Coaling Station

An Example of Modern Coaling Station Construction. Ry. Gaz., vol. 29, no. 5, Aug. 2, 1918, pp. 127-128, 4 figs. Ground plan showing track arrangement and elevation of towers of new reinforced-concrete structure at Manchester, N. Y.

Condensation on Under Surface of Roof

See Roof Construction below.

Coördination

Coördination Saves Six Weeks' Construction Time on Big Building. Eng. News-Rec., vol. 81, no. 7, Aug. 15, 1918, pp. 300-304, 5 figs. Duplicate equipment throughout eliminates plant delays; manual operations proceed on time-table schedule, promoting *esprit de corps*.

Grain Warehouse

New Reinforced-Concrete Grain Warehouse in Genoa (Nuovo magazzino in cemento armato per grani nel porto di Genova). Ingegneria Italiana, vol. 2, no. 30, July 11, 1918, pp. 17-23, 11 figs. General plans and dimensions.

Mill Buildings

A Very Modern Manufacturing Plant, W. H. Roberts. Wood-Worker, vol. 37, no. 6, Aug. 1918, pp. 32-33, 6 figs. Notes on the fireproof construction, equipment, methods, safety devices, ventilation, lighting, and sprinkler system of Weiss Mfg. Co., Monroe, Mich., manufacturers of sectional bookcases, office furniture, etc.

Is Wood a Suitable Material for the Construction of Mill Buildings? W. Kynoch and R. J. Blair. Contract Rec., vol. 32, no. 32, Aug. 7, 1918, pp. 622-623, 2 figs. Examination of facts from a technical standpoint.

Roof Construction

The Relative Effectiveness of Various Types of Roof Construction in Preventing Condensation on the Under Surface, W. S. Brown. Building News, vol. 115, no. 3317, July 31, 1918, pp. 80-81, 1 fig. Graphs obtained mainly from experiments made in testing laboratory of F. P. Sheldon and Son, Providence, R. I. Paper before Nat. Assn. Cotton Mfrs.

Shipyard

Concrete Shipyard at Wilmington, N. C., A. G. Monks. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 452-454. Description of plant erected by Liberty Shipbuilding Co., Boston, Mass., for building concrete ships.

Stacks

Boiler House as Stack Foundation, L. C. Huff. Power, vol. 48, no. 5, July 30, 1918, pp. 150-152, 5 figs. Four-story concrete building used as foundation for 240-ft. steel stack; supports and bracing to withstand wind pressure.

Warehouse

Army Depot at Chicago is Large Concrete Warehouse, A. Epstein. Eng. News-Rec., vol. 81, no. 6, Aug. 8, 1918, pp. 269-270, 1 fig. Floor area 29 acres in 6-story building; tracks on first floor; tunnels for trucking and utilities.

See also Cement and Concrete (Roofs); Labor (Housing).

CEMENT AND CONCRETE

Buildings

Economy in the Design of Concrete Buildings, C. W. Mayers. Contract Rec., vol. 32, no. 34, Aug. 21, 1918, pp. 659-662. Remarks and suggestions. Paper before Am. Concrete Inst.

Cement Gun

Varied Applications of the Cement Gun. Eng. & Cement World, vol. 13, no. 3, Aug. 1, 1918, p. 40. Recent uses and composition of mixture applied by cement gun.

Columns

Economy in the Design of Columns for Concrete Buildings, Clayton W. Mayers. Contract Rec., vol. 32, no. 36, Sept. 4, 1918, pp. 712-716, 6 figs. Aberthaw Construction Co. Before Am. Concrete Inst.

Temperature Tests on Concrete Columns, W. A. Hull. Contract Rec., vol. 32, no. 31, July 31, 1918, pp. 605-607. Résumé of tests on gravel and limestone concrete columns carried out in the U. S. Bureau of Standards. Abstract of paper before Am. Concrete Inst.

Dams

Lukewarm Concrete Enough Precaution for Zero Weather Dam Work. Eng. News-Rec., vol. 81, no. 6, Aug. 8, 1918, pp. 260-262, 3 figs. Perfect bond and sound concrete secured by placing 50-deg. mixture on frozen surfaces; concreting kept up in heavy frosts.

Deterioration

Action of Sea Water on Concrete in Structures Exposed to Tides (Action de l'eau de mer sur les ouvrages en béton exposés aux marées), E. R. Matthews. Mémoires et Comptes Rendus des Travaux de la Société des Ingénieurs Civils de France, year 71, nos. 1-3, Jan.-Mar. 1918, pp. 40-42. Results of experiments made at Hull, England, on 6-in. cubes. Abstract of paper before Soc. of Civ. Engrs., France.

Concrete in Alkali Soil at Saskatoon, H. McI. Weir. Jl. Eng. Inst. of Canada, vol. 1, no. 4, Aug. 1918, pp. 153-154. Physical condition and appearance of a number of cases in alkali ground and comparison of these with conditions found in ground free from alkali.

Deterioration of Concrete, B. Stuart McKenzie. Jl. Eng. Inst. of Canada, vol. 1, no. 4, Aug. 1918, pp. 150-152. Examples of deterioration under various conditions and results of experiments conducted by City Analyst of Winnipeg.

Foreign Concrete Regulations

English and Canadian Concrete Regulations, W. W. Pearse. Can. Engr., vol. 35, no. 7, Aug. 15, 1918, pp. 143-147. Comparison between Toronto's by-law regulating reinforced-concrete construction and new by-law of London County Council which adopts 180 lb. per sq. in. shearing stress and favors hooking the ends of reinforcing in beams.

Mortars

Ancient and Modern Mortar, W. J. Dibdin. Concrete Age, vol. 28, no. 5, Aug. 1918, p. 19. Abstract of paper before Faraday Soc. of London.

Proportioning the Materials of Mortars and Concretes by Surface Areas of Aggregates, L. N. Edwards. Contract Rec., vol. 32, No. 31, July 31, 1918, pp. 599-604, 12 figs. Methods, materials used, results obtained and phenomena observed in a series of experimental tests undertaken to develop the practical application of this method. Abstract of paper before joint meeting of Am. Concrete Inst. and Am. Soc. for Testing Materials.

Mixing

Effect of Time of Mixing on the Strength of Concrete, D. A. Abrams. Can. Engr., vol. 35, no. 6, Aug. 8, 1918, pp. 132-134, 5 figs. Comparison of hand and machine mixing; effect of rate of rotation of mixer drum; effect of age on strength; curves showing temperature of mixing water against compressive strength; yield and density of concrete. (Concluded.)

Reinforced Concrete

Discussion on Final Report of the Special Committee on Concrete and Reinforced Concrete, C. S. Bissell. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 897-903. Method for designing reinforced beams and slabs from equations given in report. (Concluded.)

Roofs

Concrete Roof Specifications. Contract Rec., vol. 32, no. 36, Sept. 4, 1918, p. 716. Recommendations of Sandusky Cement Co.

Strength of Concrete

Some Tests on the Effect of Age and Condition of Storage on the Compressive Strength of Concrete, H. F. Gonnerman. Can. Engr., vol. 35, no. 6, Aug. 8, 1918, pp. 135-137, 4 figs. Results of tests made at the Univ. of Ill. Paper before Am. Concrete Inst.

Swimming Pools

How to Build Reinforced Swimming Pools. Concrete Age, vol. 28, no. 5, Aug. 1918, pp. 10-12, 3 figs. Suggestions for designing.

Ties

Concrete on Railways. Ry. Gaz., vol. 29, no. 3, July 19, 1918, pp. 72-74, 7 figs. Shapes and sizes of blocks used as ties for rails.

Trestles

Reinforced Concrete Trestles at North Toronto. Ry. Age, vol. 65, no. 7, Aug. 16, 1918, pp. 289-291, 7 figs. Unique details developed in viaducts designed as a substitute for steel construction.

See also Fuel and Firing (Waste Heat); Marine Engineering (Concrete Ships).

CHEMICAL TECHNOLOGY

Ammonia

Notes on the Catalytic and Thermal Synthesis of Ammonia, E. B. Maxted. Jl. Soc. Chem. Industry, vol. 37, no. 14, July 31, 1918, pp. 232T-235T, 3 figs. Discussion of some points in the Haber synthesis and of methods employed and results obtained in connection with measurement of ammonia equilibrium at high temperatures.

The "Direct" Process of Sulphate Making in Gas-Works, W. S. Curphey. Gas Jl., vol. 143, no. 2879, July 16, 1918, pp. 111-113. Experiments on rotation system; effect of seasonal changes on ammonia; discussion of results of investigations carried out at various works. From annual report of chief alkali inspector. (Continuation of serial.)

Analysis, Steel

Combustion Train for Carbon Determination, J. B. Stetser and R. H. Norton. Iron Age, vol. 102, no. 8, Aug. 22, 1918, pp. 443-445, 1 fig. Apparatus giving results in 6 min. and meeting color-test inaccuracies arising from varying heat treating of samples.

The Determination of Cobalt and Nickel in Cobalt Steel, W. R. Schoeller and A. R. Powell. Iron & Steel Inst. of Canada, vol. 1, no. 7, Aug. 1918, pp. 304-306. Application of process based on precipitation of hexammine cobaltons and hexammine nickelous iodides by means of potassium iodide in strongly ammoniacal solution, the precipitation of the trivalent metals by the ammonia being prevented by addition of tartaric acid. Paper before British Iron & Steel Inst. Published also in Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 359-360; Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 22, 5 pp.

Analysis (Varia)

A Method for the Separation and Determination of Barium Associated with Strontium, F. A. Gooch and M. A. Soderman. Am. Jl. of Sci., vol. 46, no. 273, Sept. 1918, pp. 538-540. Results of attempt to adapt process used for separating barium from calcium and magnesium, which consists in throwing the barium out of solution by the addition of a 4:1 mixture of concentrated hydrochloric acid and ether.

A New Method of Estimating Zinc in Zinc Dust, L. A. Wilson. Eng. & Min. Jl., vol. 106, no. 8, Aug. 24, 1918, pp. 334-336, 1 fig. Abstract from paper before Am. Soc. for Testing Materials.

Charcoal

Charcoal and Allied Industries (La destilación de la madera). Boletín de la Sociedad de Fomento Fabril, year 35, no. 4, Apr. 1918, pp. 244-249. Processes used with different woods; obtainable by-products and their temperatures of distillation. (To be continued.)

Coal-Tar Products

Constituents of Coal Tar, P. E. Spielmann. Gas Jl., vol. 143, no. 2879, July 16, 1918, p. 114. Enumeration of multiple six-ring and of five-member ring hydrocarbons. (Continuation of serial.)

Notes on the Commercial Fractional Separation of Benzene, Toluene, and Xylenes, T. H. Butler. Jl. Soc. Chem. Industry, vol. 37, no. 14, July 31, 1918, pp. 220T-222T, 5 figs. Factors making efficiency in plants of coal-tar hydrocarbons.

The Recovery of Light Oils and Refining of Toluol. Engineering, vol. 106, no. 2743, July 26, 1918, pp. 83. Sources of light oils, coal gas, water gas and oil gas; outline of processes; scrubbers, heat exchangers, superbeater and stripping still, wash-oil cooler, condenser, separator, crude rectifying stills, agitator and rectifying stills.

Dyestuffs

Dyestuffs, L. J. Matos. Jl. Franklin Inst., vol. 186, no. 2, Aug. 1918, pp. 187-209, 8 figs. History of development of dye industry; chemistry of industry; diagrams illustrating manufacture of certain dyestuffs.

Filter

A New Form of Ultra-Filter. Jl. Am. Chem. Soc., vol. 40, no. 8, Aug. 1918, pp. 1226-1230, 2 figs. Laboratory arrangement consisting essentially of dializer and pervaporator connected by a siphon.

Glass

Electrothermic Methods of Glass Manufacture (Métodos electrotérmicos para la fabricacion del vidrio). Boletin de la Sociedad de Fomento Fabril, year 35, no. 3, Mar. 1918, pp. 161-170, 10 figs. Four types of furnaces: Becker, Brown, Jablochkoff, and Sauvageon.

Scientific Glassware, Morris W. Travers. Jl Soc. Chem. Industry, vol 37, no. 14, July 31, 1918, pp 235T-239T. Account of efforts to replace Jena glass in recently established factory at Walthamstow England.

The Manufacture of Optical Glass, S. A. Hand Am. Mach., vol 49, no. 9, Aug. 29, 1918, pp 367-372, 7 figs. History of demand for optical glass and attempts to produce it finally resulting in success at Jena. The solving of the problem in America and its production here.

Laboratory

Equipping a Shop Laboratory. Machy., vol. 24, no. 12, Aug. 1918, pp. 1087-1090, 5 figs. Arrangement of shop laboratory and brief explanation of methods used in analysis of iron and steel.

Nitrates

The Nitrogen Problem in Relation to the War, A. A Noyes. Sci. Am. Supp., vol. 86, no 2224, Aug. 17, 1918, pp. 98-99. Resources and methods for making materials required for explosives. Paper before joint meeting of Wash. Acad. of Sciences and Chem. Soc. of Wash. From Jl. of Wash. Acad. of Sciences.

Oil Industry

A New British Oil Industry, E. H. Cunningham Craig, F. M. Perkin, A. G. V. Berry and A. E. Dunstan. Jl Inst. Petroleum Technologists, vol. 4, no. 15, Apr. 1918, pp. 110-134. Processes to obtain oil by distillation from oil-shales, coal, cannel coals and torbanites, blackband ironstones, lignite and peat.

Make More Gasoline From Petroleum, and Toluol, Too, Louis Bond Cherry. Automotive Eng., vol. 3, no. 7, Aug. 1918, pp 319-320. Further details of process described in Jan. 1918 issue.

The Burton Process of Refining Petroleum, Burton. Petroleum Rev., vol. 39, nos. 833 and 834, July 6 and 13, 1918, pp. 5-6 and 31. How it was invented and developed. From address before Am. Chem. Soc.

Oils, Vegetable

On Refining of Niitzu Crude Oil (in Japanese), M. M. Ozuta and Kenzo Sato. Jl. Soc. M. E., Tokyo, vol. 21, no. 53, July 1918.

Peat

Galeine and Houlbert Apparatus for the Distillation of Peat (Appareil, système Galcine et Houlbert, pour la distillation des tourbes). Génie Civil, vol. 73, no. 2, July 13, 1918, pp. 31-35, 2 figs. Scheme and operation.

The Nitrogen Distribution in Peat from Different Depths, C. S. Robinson and E. J. Miller. Jl. Am. Peat Soc., vol. 11, no. 3, July 1918, pp. 158-191, 8 figs. Experimental work: Study of variation in nitrogen partition in peat with depth or age and state of decomposition; comparison of its composition with that of pure proteins; nitrogen availability as determined by the alkaline permanganate method. Reprint of Mich. Agri. College, Tech. Bul. no. 35.

Periodic Table

A Modification of the Periodic Table, Ingo W. D. Hackh. Am. Jl. of Sci., vol. 46, no. 273, Sept. 1918, pp. 481-501, 2 figs. Prediction that no new gas can be discovered from periodic curves obtained by plotting the atomic weights of the known elements by their relative position in the displacement series and by their polar numbers; account for formation of such groups as Fe-Co-Ni, Ra-Rh-Pd, Os-Ir-Pt, and the rare earths; tables showing the close relationship between polar number and isomorphism and the periodicity of the specific gravity; system of the radioactive elements.

Potash

The Estimation of Potash, B. Blount. Chem. News, vol. 117 no. 3052, July 19, 1918, pp. 242-244. Method for the estimation of potash in siliceous rocks, clays, etc., by treatment with hydrofluoric and sulphuric acids.

The Prospects of Founding a Potash Industry in This Country, K M Chance. Iron & Coal Trades Rev., vol. 97, no. 2630, July 26, 1918, pp. 86-87. Paper, with discussion, before Soc. of Chem. Industry, Bristol, July 1918.

Rubber

The Object of the Vulcanization Process. India-Rubber Jl., vol. 56, no. 2, July 13, 1918, p. 9. Description of changes brought about.

What the Rubber Chemists Are Doing. India Rubber World, vol. 58, no. 5 Aug. 1, 1918, pp. 651-655. Influence of sodium sulphate, formalin, soda, bisulphite of soda, sodium thiosulphate, sodium acetate, and sulphurous acid on the inherent properties; determination of nitrogen; comparative physical tests.

Sulphite

Bisulphite Liquor and Its Constituents, J. Beveridge. Paper, vol. 22, no. 23, Aug. 14, 1918, pp 11-14. Study of the waste problem and suggestions for the recovery of useful materials.

Sulphite Pulp Manufacture, R. E. Cooper. Paper, vol 22, no. 25, Aug. 28, 1918, pp. 11-13. Chemistry of process and details of various operations.

Wool

Present Practice in Wool Carbonization, Textile World Jl., vol. 54, no. 6, Aug. 10, 1918, pp. 25-27. Comparison of methods in present practice.

CLAY

(See Brick and Clay)

COAL INDUSTRY

Briquetting

The Briquetting of Lignites, R. A. Ross. Jl. Eng Inst. of Canada, vol. 1, no. 4, Aug. 1918, pp. 162-166. Feasibility of meeting fuel requirements in Saskatchewan and Manitoba by utilizing prepared lignites and sub-bituminous coals.

The Briquetting of Western Lignites, R. A. Ross. Contract Rec., vol. 32, no. 34, Aug. 21, 1918, pp 651-654. Present state of the art of producing carbonized lignite briquets; equipment recommended; commercial conditions; procedure. From report to Advisory Council for Scientific and Industrial Research.

Carbonization

Aspects of Low Temperature Carbonization of Coal, E. C. Evans. Jl. Soc. Chem. Industry, vol. 37, no. 14, July 31, 1918, pp. 212T-219T. Historical notes; theory of coking process; main differences in oven design for high- and low-temperature carbonization processes; cost of plant. Published also in Colliery Guardian, vol. 116, no. 3304, July 26, 1918, pp. 176-177; Iron & Coal Trades Rev., vol. 97, no. 2630, July 26, 1918, pp. 88-89. Paper before Soc. of Chem. Industry.

Low Temperature Carbonization of Coals, J. L. Stevens Chem. Eng. & Min. Rev., vol. 10, no. 114, March 1918, pp. 167-170, 2 figs. Mashek process for carbonizing lignite up to 500 deg. cent.; chemistry of coal. (Continuation of serial.)

Coal Deposits

Coal Deposits in the Llapo District (Los yacumientos carboniferos del distrito de Llapo), A. P. Figuerola. Boletin del Cuerpo de Ingenieros de Minas del Perú, no. 89, 24 pages, 1 map. Geography of the carboniferous district of Llapo; coal deposits; quality of the coal.

The Santo Tomas Cannel Coal, Webb Co., Tex. George H. Ashley. Department of the Interior, U. S. Geol Survey, Bul. 691-I, July 25, 1918, pp. 251-270, 12 figs. General features of the region; physical and chemical properties of the coal; analyses, geologic relations of coal beds; mines and mining.

Coking

An Innovation in the Coke Industry, John L. Gans. Coal Age, vol. 14, no. 6, Aug. 8, 1918, pp. 256-257. Entrance of beehive coke interests into the realm of by-product coke manufacture.

Some Characteristics of American Coals in By-Product Coking Practice, F. W. Sperr. Jl. Franklin Inst., vol. 186, no. 2, Aug. 1918, pp. 133-163, 20 figs. Relations of the by-product coke industry to modern warfare; technical phase of the subject.

The By-Product Coke Oven; Its Products, W. H. Blauvelt. Blast Furnace & Steel Plant, vol. 6, no 9, Sept. 1918, p. 392. Coke oven gas; recovery of benzol. Paper before Am. Inst. Min. Engrs.

Labor Situation

The Labor Situation, R. Dawson Hall. Coal Age, vol 14, no. 8, Aug. 22, 1918, pp. 365-367. General review of labor question in coal mines.

Micro-Chemical Examination

Micro-Chemical Examination of Coal in Relation to its Utilization, J. Lomax. Gas World, vol. 69, no. 1772, July 6, 1918, pp. 18-19. Methods used; results and their significance; carbonization results.

Mining

Can Output Be Increased Scientifically? W. E. Joyce. Coal Age, vol. 14, no. 8, Aug. 22, 1918, pp. 356-357. Writer believes a little modern science would increase coal output.

Coal Mining in Carbonado, Washington, F. G. Jarrett. Coal Age, vol. 14, no. 7, Aug. 15, 1918, pp. 308-312, 7 figs. Description of operations in very rough country.

Methods of Operation, J. F. K. Brown. Coal Age, vol. 14, no. 7, Aug. 15, 1918, pp. 313-315. Conditions influencing methods of coal mining.

Scraper Mining of Thin Bed Anthracite, E. P. Humphrey. Coal Age, vol. 14, no. 7, Aug. 15, 1918, pp. 316-318, 4 figs. Loading coal by means of a V-scraper driven by power.

Wasteful Methods in Mining, R. G. M. Bathgate. Sci. & Art of Min., vol. 28, no. 26, July 27, 1918, pp. 473-475. Conditions in Indian coalfields. From presidential address before Mining and Geological Inst. of India.

War Conditions

The Coal Problem Under War Conditions, H. H. Stoek, Coal Age, vol. 14, no. 9, Aug. 29, 1918, pp. 393-396. Discussion, with suggestions, of present situation.

Washing

A New Method of Separating Slate from Coal, H. M. Chance. Jl. Engrs' Club of Phila., vol. 35-8, no. 165, Aug. 1918, pp. 369-377 and (discussion) 377-378, 6 figs. Survey of apparatus in present use; new methods of effecting separation by means of agitated mixture of sand and water constituting a fluid mass of relatively high specific gravity, in which the coal floats and the slate sinks; application of this principle to other ore-dressing problems. Paper before Engrs.' Club.

Notes on Coal Washing, L. Crawford. Gas World, vol. 69, no. 1172, July 6, 1918, pp. 14-15. Principle of the separation by washing of two particles of equal diameter; table of variations in size or in density necessary to produce appreciable variations in rate of fall, calculated from Rittinger's empirical formula for the limiting velocities of fall of various particles.

The Rheolaveur, W. Galloway. Proc. South Wales Inst. of Engrs., vol. 34, no. 2, July 19, 1918, pp. 105-112, 7 figs. Description of appliance for washing small coal along a sloping trough in a stream of water. From Bul. de la Société de l'Industrie Minérale.

CONCRETE

(See Cement and Concrete)

CONVEYING

(See Hoisting and Conveying)

DESICCATION

(See Drying)

DOCKS

France

American-Built Docks in France Completed by Pacific Coast Engineers, Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, pp. 208-216, 22 figs. Illustrated account of building of 4100-ft. structure.

New Orleans

New Orleans Builds Inner Harbor and Navigation Canal. Eng. News-Rec., vol. 81, no. 7, Aug. 15, 1918, pp. 304-307, 3 figs. Provides ocean docks and industrial sites on fixed level waterway between Mississippi River and Lake Pontchartrain.

DRYING

Evaporators

Liquid Level Control. Paper Mill, vol. 41, no. 36, Sept. 7, 1918, pp. 22-23 and 46, 2 figs. Device for automatically maintaining liquid levels in evaporators, closed and open tanks, etc., also for draining condensate from heating, drying, cooking and evaporating apparatus.

Low Temperature

Marmier and Canonne Apparatus for drying or Concentrating Liquids at Low Temperatures (Appareil Marimier et Canonne pour la dessiccation ou la concentration des liquides à basse température). Génie Civil, vol. 73, no. 4, July 27, 1918, p. 72, 1 fig. Apparatus operates under reduced pressure down to 37 deg. and is designed for preparation of concentrated serums and organic liquids.

Warm-Air Circulation

Drying by Warm Air Circulation. Eng. Rev., vol. 32, no. 1, July 15, 1918, pp. 14-16, 3 figs. Description of system adopted by the Sturtevant Eng. Co.

ELECTRICAL ENGINEERING

A. C. Motors

Calculation of Performance of Induction Motors Working in Conjunction with Flywheels and Slip Regulators, Herbert Vickers. Elecn. vol. 81, no. 12, July 19, 1918, pp. 248-250. Mathematical treatment of both the continuous and the intermittent slip regulator; also automatic slip regulator and Ward Leonard system.

Control of Induction Motors, C. E. Clewell. Elec. Wld., vol. 72, no. 10, Sept. 7, 1918, pp. 438-441, 12 figs. Fundamental methods outlined and explained; resistance-type starter, auto-transformer method, the use of the choke-coil feature and of so-called preventive resistance; automatic compensator.

The Commercial Application of Synchronous Motors, M. J. McHenry. Elec. News, vol. 27, no. 13, July 1, 1918, pp. 33-36, 2 figs. Attempt to point out principal characteristics which make synchronous motors applicable to certain classes of service, and discussion of industrial use of these motors in relation to central station and its customers.

A. C. Rectifier

An Interesting Alternating Current Rectifier for Charging Accumulators. Wireless World, vol. 6, no. 65, Aug., 1918, pp. 271-272, 1 fig. Device operating by means of a vibration tongue, which, actuated by magnets in circuit with alternating supply, automatically connects line first to one pair of contacts, then the other, in synchronism with supply current.

Armature Heating

Armature Heating in Traction Motors, L. Adler. Elecn. vol., 81, no. 2099, Aug. 9, 1918, pp. 311-312, 5 figs. Abstract of an article in Electrotechnische Zeitschrift, no. 26, 1917.

Bells

Electricity in Mining, L. Fokes, Sci. & Art of Min., vol. 28, no. 26, July 27, 1918, pp. 472-473, 1 fig. Construction, operation and comparison of trembler and single-stroke bells; resistance of bell coils. (Continuation of serial.)

Condensers

Static Condensers, W. B. Taylor. Gen. Elec. Rev., vol. 21, no. 8, Aug., 1918, pp. 565-569, 8 figs. Effect in service of using static condensers on circuits of low power factor, and comparison of this service with that afforded by installing additional feeder copper.

Dynatron

The Dynatron, A. W. Hull. Wireless Age, vol. 5, no. 11, Aug., 1918, pp. 941-951, 12 figs. Formulæ and calculations for the dynatron, a vacuum tube claimed to possess negative electric resistance; applications of the dynatron to radio work. (Continued.)

Electrodeposition

Construction and Operation of Electrolytic Copper Refinery, J. E. McAllister. Eng. & Min. Jl., vol. 106, no. 8, Aug. 24, 1918, pp. 337-341, 1 fig. From first report of Cadanian Munition Resources Commission.

Experiments with the Copper Cyanide Plating Baths, Frank C. Mathers. Metal Indus., vol. 16, no. 8, Aug., 1918, pp. 359-360. Paper before Am. Electro-Chem. Soc., May, 1918.

The Process of Depositing Silver on Glass and China, Howard Pearsall. Brass World, vol. 14, no. 6, June 1918, pp. 157-158. Formulæ and directions.

Electromagnets

The Stroke of an Alternating-Current Electromagnet, A. Thomälen. Elecn., vol. 81, no. 2097, July 26, 1918, pp. 267-268, 6 figs. Abstract of an article in Electrotechnische Zeitschrift, no. 39. A mathematical treatment.

Frictional Electricity

Experiments on Tribo-Electricity, P. E. Shaw. Elecn., vol. 81, no. 10, July 5, 1918, p. 209. Experiments in frictional electricity with solid bodies rubbed together under different physical conditions. Abstract of paper in Proc. of the Royal Soc.

Furnaces

Electric Furnace for Melting Alloys, William H. Easton. Elec. World, vol. 72, no. 7, Aug. 17, 1918, pp. 295-297, 3 figs. Control apparatus must be carefully selected to provide for heavy fluctuation of load; graphic records of power demand when melting nichrome and nickel steel in electric furnaces.

Temperature Uniformity in an Electric Furnace, J. B. Ferguson. Phys. Rev., vol. 12, no. 1, July 1918, pp. 81-94, 9 figs. Discussion of essential conditions for a proper control of temperature distribution and of previous attempts made to secure these conditions; description of a type of horizontal furnace designed for investigation requiring a uniform temperature over the range 620-1190 deg.

Fuses

The Development of 2500-Volt Fuses, Robert Charles Cole. Elec. World, vol. 72, no. 10, Sept. 7, 1918, pp. 436-437. Experimental investigations leading to development of a fuse that is not destroyed by modern high-power short circuits.

Generators

A Direct-Current Generator for Constant Potential at Variable Speed, S. R. Bergman. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 8, pp. 1011-1018, 6 figs. Theory, diagrams of connections, and performance curves of a machine claimed to be self-excited and capable of inherent and instantaneous regulation independent of speed, load and heating.

Generators Employed in Telephone Exchanges. Elec. Rec., vol. 24, no. 3, Sept. 1918, pp. 67-69, 12 figs. Construction and use in modern common-battery telephone exchanges.

High-Speed Turbo-Generators. Practical Engr., vol. 58, no. 1641, Aug. 8, 1918, pp. 64-66, 7 figs. Survey of various methods of construction adopted by manufacturers in design of turbo alternators, and consideration of special characteristics of turbo direct-current machines.

Magnetic Pull in Electric Machines, E. Rosenberg. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 9, Sept. 1918, pp. 1069-1113, 19 figs. Investigates whether in a given machine there is a "critical induction" which gives a higher unbalanced pull than any other induction, and also the permissible deflection of machine parts in connection with the unbalanced pull, and influence of latter on critical speed.

One Way of Raising the Output of an Electric Generator (Sur un moyen de forcer la puissance d'un générateur électrique), Ch. Vallet. L'Industrie Electrique, year 27, no. 626, July 25, 1918, pp. 265-267. Numerical comparison of three systems of cooling an electric machine. (Concluded.)

Harmonics

Higher Harmonics in Polyphase Electric Systems, V. Karapetoff. Elecn., vol. 81, no. 12, July 19, 1918, pp 250-251. Abstract of paper before Am. Assn. for Advancement of Science.

Inductive Interference

Inductive Effects of Alternating Current Railroads on Communication Circuits, H. S. Warren. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 8, Aug. 1918, pp. 1019-1048. Discussion of inductive interference in general and in electrified railroads, including reference to work of Joint Committee on Inductive Interference in California; description of four important installations of railroad electrification and specific means adopted in each case for preventing interference, with degree of success which has been met with.

Lamps

Lamp Policy of the Fuel Administration. Elec. World, vol. 72, no. 10, Sept. 7, 1918, pp. 457-460. Program of Federal authorities, by eliminating inefficient types of incandescent lamps, is expected to save more than 1,000,000 tons of coal a year.

Lightning Arresters

The Oxide Film Lightning Arrester, Crosby Field. Gen. Elec. Rev., vol. 21, no. 9, Sept., 1918, pp. 597, 6 figs. Description of construction and principle of apparatus.

The Oxide Film Lightning Arrester, Charles P. Steinmetz. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 590-596, 8 figs. Short history of lightning protection of electric systems, ranging from the early communication circuits to the present high-tension, high-capacity transmission lines, employing small air gaps and the aluminum-cell lightning arrester; oscillograph records of tests on the oxide film arrester and discussion of its principle of operation.

Magnetos

Non-Distributor and Multipolar Magnetos, F. I. Hoffman. Automotive Industries, vol. 39, no. 6, Aug. 8, 1918, pp. 222-223, 16 figs. Discussion of practical possibilities of magnetos designed for use with separate distributors on the engine camshaft—multipolar magnetos delivering up to six sparks per revolution.

Motor Mounting

Notes on Electric Motor Mounting (Note sur le montage des moteurs électriques), A. Curchod. Revue Générale de l'Electricité, vol. 4, no. 5, Aug. 3, 1918, pp. 145-150, 20 figs. Diagram of connections for each of different types.

Power Factor

Effect of Power Factor on Central-Station Operation, Will Brown. Elec. Rev., vol. 73, no. 6, Aug. 10, 1918, pp. 199-202, 6 figs. Good voltage regulation and transmission efficiency can be obtained by installing synchronous motors.

Improving Power Factor by Static Condenser. Elec. Rev., vol. 73, no. 9, Aug. 31, 1918, pp. 317-320, 6 figs. Importance of high power-factor; application and sphere of the static condenser, with concrete examples and instances of its use.

Practical Limitations to Power Factor Correction, Ralph Kelly. Elec. Rev., vol. 73, no. 7, Aug. 17, 1918, pp. 243-244, 3 figs. Influence of location of corrective apparatus upon generator and conductor capacity and voltage regulation; proportioning of kilovolt-amperes and kilowatts; summation of individual power factors.

Radio Engineering

High Power Stations, C. H. Taylor. Wireless Age, vol. 5, no. 11, Aug. 1918, pp. 931-936, 2 figs. Features of the long-distance stations of the Am. Marconi Co. (Continued.)

Present State of Long Distance Radio-Telegraphy and the French Transoceanic Network (L'etat actuel de la radiotélégraphie a grande distance et le réseau transocéanique français), Leon Bouthillon, Génie Civil, vol. 73, no. 5, Aug. 3, 1918, pp. 84-98, 22 figs. Principles of operation of apparatus used and description of processes in large stations.

Progress in Radio Science. Wireless Age, vol. 5, no. 12, Sept. 1918, pp. 979-985, 10 figs. Apparatus devised for rectifying spark gap for high-tension alternating current; details of spark discharge for radio frequency oscillation circuits; x-ray tube wherein length of focus of cathode rays is varied at will of operator.

Progress of Wireless Telephony, E. E. Bucher. Wireless Age, vol. 5, no. 12, Sept. 1918, pp. 1014-1019, 7 figs. Diagram of Espenschied's duplex system and Englund's duplex simultaneous telephone and telegraph system.

Single-Impulse Radiography (Instantaneous): Its Limitations and Possibilities, R. Knox. Jl. Inst. Elec. Engrs., vol. 56, no. 275, June 1918, pp. 352-358. Development of method; comparison of exposures obtained from single-impulse set with mercury dip interrupter and from Siemens impulse outfit; types of apparatus, experiments to show differences obtained when exposing through screen on to plate and through glass on to plate and screen; standardization and technique.

Sub-tations

The Standard Outdoor Substation, J. T. Bronson. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 640-651, 22 figs. Requirements of outdoor switching apparatus; outline of types and equipments of outdoor substations.

Telephones

Automatic Telephones at Australia House London. Elecn., vol. 81, no. 2099, Aug. 9, 1918, pp. 317-318, 2 figs. Description of automatic exchange providing for 200 lines.

Construction and Operation of the Field Telephone and Buzzer, R. D. Greeman. Wireless Age, vol. 5, no. 12, Sept. 1918, pp. 1033-1035, 2 figs. Design of 4000-ft. signal set intended for junior military organizations.

European Telephone Practice, F. W. Scholz. Telephone Engr., vol. 20, nos. 2 and 3, Aug. and Sept. 1918, pp. 83-87, 9 figs., pp. 130-133, 6 figs. (Aug.) Artificial lines; location of defects in underground cables; Castelli apparatus for simultaneous telegraphing and telephoning; French measures to save materials. (Sept.) Chemical and physical theory of lead storage battery; some points on wireless telephony; new telephone selector used in France. (Translations from Revue Générale de l'Electricité and Annales des Telephones.)

Telephone Exchange Transfers and Their Organization, G. C. Baldwin. Jl. Inst. Elec. Engrs., vol. 56, no. 275, June 1918, pp. 390-410, 24 figs. Operations for actual transfer and consideration of engineering processes accompanying work.

Transformers

Current Transformer Ratio and Phase Error by Test Ring Method, H. S. Baker. Proc Am. Inst. Elec. Engrs., vol. 37, no. 9, Sept. 1918, pp. 1173-1183, 6 figs. Method of testing by connecting the primary and secondary of transformer under test respectively in series with the primary and secondary of a special current transformer in which number of turns in secondary coil is varied until primary and secondary ampere turns in special transformer are equal to each other.

Radiator Tank Transformer, H. O. Stephens and A. Paline. Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 556-559, 8 figs. Construction rules and details of the latest forms.

Transient Phenomena

Reactance and Short Circuit Current, R. E. Doherty, Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 562-564, 7 figs. Non mathematical dissertation of quantitative effect of reactance on short-circuit currents.

Short Circuit Windings in Direct-Current Solenoids, O. R. Schurig. Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 560-562, 2 figs. Application to designs of the phenomenon consisting in the prolongation of time taken by flux to decay after removal of the magnetizing force when a short-circuited winding surrounds a magnetic core.

Transmission Lines

Aerial Cable Construction Kinks. Telephony, vol. 75, no. 6, Aug. 10, 1918, pp. 13-15. Methods and devices developed in construction of section between New York and Albany which facilitated rapid placing of cable.

Aerial Line Construction in France, H. G. A. Sansom. Transmitter, vol. 28, no. 3, July 18, 1918, pp. 19-24, 11 figs. Lecture before Victorian Postal Elec. Soc.

Detective and Protective Devices for Electric Cables. Engineer, vol. 126, no. 3267, Aug. 9, 1918, p. 116, 3 figs. Description of protective system for use with test sheath cables.

Resistance and Reactance of Iron Transmission Lines, A. Press. Elecn., vol. 81, no. 2097, July 26, 1918, pp. 275-277, 3 figs. A mathematical treatment.

Voltage Regulators

Voltage Regulator for Combined Lamp and Motor Circuits. Electricity, vol. 32, no. 1445, July 19, 1918, p. 379, 4 figs. Circuits and vector relationship of "stabilizer" developed by the General Electric Co.

ENGINEERING MATERIALS

Babbitt Metal

Babbitt Metals: Conservation of Tin. Elec. Power Club, Bul. no 703, July 1918, p. 1. Composition of two babbitt mixtures used by the General Electric Co. and of two tin alloys used by Westinghouse Elec. & Mfg. Co.

Bluestone

Methods of Quarrying Bluestone. Stone, vol. 39, no. 8, Aug. 1918, pp. 366-368. Characteristic structure of bluestone; difference between bluestone quarrying and other types.

Boiler Plates

A Cause of Failure in Boiler Plates, W. Rosenhain and D. Hanson. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 15, 12 pp., 18 figs. Results of analysis, mechanical tests and microscopic examination of a boiler plate, 1¾-in. thick, 4 ft. 4 in. wide by 11 ft. long, which failed in the last stage of its manufacture.

Brass

Cast Brass, Its Use and Reclamation, R. C. Brown. Railroad Herald, vol. 22, no. 9, Aug. 1918, pp. 186-187. Suggested scheme to gage service efficiency of the brass account of a railroad.

Bronze (Phosphor)

The Manufacture of Phosphor Bronze, W. W. Rogers. Mach. World, vol. 63, no. 1642, June 21, 1918, p. 297. Composition, method of manufacture, and physical properties. From pamphlet published by Stamford (Conn.) Rolling Mills Co.

Cadmium

The Allotropy of Cadmium, E. Cohen. Jl. Am. Chem. Soc., vol. 40, no. 8, Aug. 1918, pp. 1149-1156, 3 figs. Aiming to demonstrate that in assumptions made by F. H. Getman (vol. 39, 1917, p. 1806), there are errors which when removed, make his results identical with those obtained by Cohen and Helderman.

Copper

Copper. Circular of the Bureau of Standards, no. 73, June 25, 1918, 103 pp., 25 figs. Source, metallurgy, refining and uses of commercial grades; possible allotrophy; chemical and physical properties; casting; deoxidation, working, welding, hardening and electrodeposition; heat treatment; effect of impurities on physical properties; definitions and specifications.

Ferrochrome

Ferrochrome, R. M. Keeney. Colo. School of Mines Mag., vol. 8, no. 8, Aug. 1918, pp. 143-147. Process of manufacturing ferrochrome from domestic chromite, recovery and carbon control as affected by grade of ore smelted, grade of product desired, and constituents of the charge.

Flint

Domestic Flint Pebbles and Linings Supplant the Foreign. Eng. & Cement World, vol. 13, no. 3, Aug. 1, 1918, pp. 61-62. Sources of grinding pebbles or substitutes thereof produced in the United States during the last few years.

Paving Blocks

Paving Blocks from Kettle River Quarries. Eng. & Cement World, vol. 13, no. 3, Aug. 1, 1918, p. 64. Appearance of rock, method employed in quarrying it, and result of analysis.

Sand

Tests Uncover Domestic French Sand Substitute, C. P. Karr. Foundry, vol. 66, no. 313, Sept. 1918, pp. 402-403. Thorough investigation conducted with different molding sands shows Zanesville product closely approaching French sand in desirable qualities.

Scrap Metal

Standard of Classification for Old Metals. Steel & Metal Digest, vol. 8, no. 8, Aug. 1918, pp. 479 and 515. Adopted by the Nat. Assn. of Waste Material Dealers.

Silica

Economic Uses of Silica and Its Occurrence in Eastern Canada, Heber Cole. Iron & Steel Inst. of Canada, vol. 1, no. 7, Aug. 1918, pp. 306-310. Requirements of silica in glass industry; in manufacture of brick, ferro-silicon, sodium silicate; in pottery and enameling; in paint manufacture; for use as a flux; in producing carborundum; in steel foundries.

Stellite

Notes on Stellite (Quelques observations sur "le stellite"), L. Guillet and H. Godfroid. Revue de Métallurgie, year 15, no. 4, July-Aug. 1918, pp. 339-346, 7 figs. Physical characteristics; structure; chemical analysis; report of author's tests.

Tantiron

Tantiron. Engineering, vol. 106, no. 2745, Aug. 9, 1918, pp. 154-156, 8 figs. Description of a silica iron used for manufacturing chemists' materials, that resists certain corrosive actions.

Textiles

Investigations on Textile Fibers, W. Harrison. Proc. Roy. Soc., vol. 94, no. A 663, July 1, 1918, pp. 460-469, 12 figs. Report of investigations on the effect of stress, moisture and heat; probable cause of the double refraction exhibited by natural fibers and effect of chemical treatment on it; experiments with artificial samples to ascertain in what manner internal stresses can arise in fibers.

Zinc

General Congress of the "Genie Civil." Work done by Section IV (Congrès général du Génie civil. Travaux de la Section IV), Demenge and Maneuvrier. Revue Générale de l'Electricité, vol. 4, no. 5, Aug. 3, 1918, pp. 157-161. Report on production and utilization of zinc throughout the world. (Continuation of serial.)

New Uses for Zinc, A. P. Cobb. Steel & Iron Digest, vol. 8, no. 8, Aug. 1918, pp. 477-479. Suggestions to dispose of the world's production—greatly increased by the war. Address before Am. Zinc Inst.

See also Aeronautics (Wing Fabrics), Building and Construction (Mill Building), Cement and Concrete, Metallurgy, Railroad Engineering, Steam (Rail Failures); Refractories; Steel and Iron; Testing (Balloon Fabrics.)

FACTORY MANAGEMENT

Cost System

Factory Order and Cost System, W. H. Rohr. Wood-Worker, vol. 37, no. 6, Aug 1918, pp. 23-25, 7 figs. System designed and operated by Waddell Mfg. Co., Grand Rapids, Mich., manufacturers to order of carvings, turnings, twist work, etc., for interior finish factory trade.

Managership

Under New Management—The Manager, Charles M. Horton. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 113-116. The human qualities of the manager who will succeed in the immediate future.

Mechanical Handling of Materials

Mechanical Material Handling System Reduces Labor and Hauling Costs and Eliminates Waste in Construction of Michigan Road. Eng. & Contracting, vol. 50, no. 10, Sept. 4, 1918, pp. 233, 4 figs.

Non-Repetitive Work

Managing Non Repetitive Work, Norman Howard. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 94-96, 3 figs. How to set times on lathe work in tool making.

Organization

The Spirit of the Organization, William Judson Kibby. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 117-118. How it is created and sustained.

Rate System

Automatic Rate System Is Fair to All, Harold W. Clapp. Elec. Ry. Jl., vol. 52, no. 6, Aug. 10, 1918, pp. 230-231. A year's experience with a service-at-cost franchise in Westerville, Ohio, shows desirability of flexible fares automatically adjusted.

Railway Stores

Railway Stores Methods and Problems, W. H. Jarvis. Ry. Gaz., vol. 29, nos. 2, 3, 4 and 5, July 12, 19, 26, Aug. 2, 1918, pp. 42-44, 75-78, 102-105 and 130-133, 1 fig. Storage and distribution of material; stores fittings; limitation of stock on hand; standard numbering of items; traffic stores requisitions. (Continuation of serial.)

Economic Factors Connected With Storing, H. B. Twyford. Iron Age, vol. 102, no. 7, Aug. 15, 1918, pp. 395-398, 2 figs. Proper quantities of materials and supplies to keep in stock; consideration of maximum and minimum limits.

Snow Removal

Snow Removal, H. Richards, G. T. Donoghue and W. J. Galligan. Jl. West, Soc. Engrs., vol. 23, no. 3, Mar. 1918, pp. 175-191. Reports of Chicago commissioners describing work carried out in their respective districts. Paper before Western Soc. of Engrs. Published also in Contract Rec., vol. 32, no. 36, Sept. 4, 1918, p. 720.

Stocks

Fixing Quantities of Materials in Stock, E. W. Taft. Cassier's Eng. Monthly, vol. 54, no. 1, July 1918, pp. 43-45, 1 fig. A method to determine and periodically to revise maxima and minima of materials stocked by industrial concerns.

See also Industrial Organization.

FORGING

Machine Forging

Machine Forging in Automotive Plants. Automative Industries, vol. 39, no. 8, Aug. 22, 1918, pp. 327-329. Methods employed in the production of upset or annular forgings.

FOUNDRY

Brass Castings

Expansion and Contraction of Brass Castings, P. W. Blair. Metal Indus., vol. 16, no. 8, Aug. 1918, p. 351. Table of contractions.

Cast-Iron Joints

The Manufacture of Metal Beds, Frank A. Stanley. Am. Mach., vol. 49, no. 10, Sept. 5, 1918, pp. 427-431, 16 figs. Illustrates and describes methods used in pouring cast-iron joints with work set up in assembling fixtures and with chills for each joint in which parts are gripped and held ready to receive the metal.

Copper Castings

Copper Castings for Electrical Purposes, G. F. Comstock. Brass World, vol. 14, no. 8, Aug. 1918, pp. 229-230. Difficulty of making copper castings of sufficient soundness without decreasing electrical conductivity of the copper.

Cores

Accuracy in Setting Cores, J. V. Hunter. Am. Mach., vol. 49, no. 10, Sept. 5, 1918, pp. 439-440, 3 figs. Methods for supporting cores by walls of flask.

Exceptional Gang Core Boxes, J. V. Hunter. Am. Mach., vol. 49, no. 9, Aug. 29, 1918, pp. 377-380, 10 figs. Description of a method of greatly increasing number of cores in a gang box; gang boxes of "Cook" type.

Deformation of Steel Castings

The Deformation of Steel Castings, T. Brown. Foundry, vol. 66, no. 313, Sept. 1918, pp. 411-413. From paper before British Foundrymen's Assn.

Die Casting

Aluminum-Bronze Die Casting, H. Rix and H. Whitaker. Metal Ind., vol. 6, no. 8, Aug. 1918, pp. 361-363, 1 fig. The effects of iron and manganese on copper-aluminum alloys. A paper before the British Institute of Metals.

Electric Brass Furnace

A Rocking Electric Brass Furnace, H. W. Gillett and A. E. Rhoads. Brass World, vol. 14, no. 18, Aug. 1918, pp. 217-220, 2 figs. Review of electric brass furnaces and description of one used by Bureau of Mines.

Foundries

How One Steel Foundry Met the Need for Ship and Railway Castings, H. Cole Estep. Foundry, vol. 66, no. 313, Sept. 1918, pp. 415-423, 15 figs. Description of plant of Birdsboro (Pa.) Steel Foundry & Machine Co.

FUELS AND FIRING

Canada

Fuels of Western Canada, James White. Jl. Eng. Inst. of Canada, vol. 1, no. 4, Aug. 1918, pp. 155-162. Availability of coal, natural gas, petroleum, electricity, peat and wood in Manitoba, Saskatchewan, Alberta and British Columbia.

Change-Fuel Systems

Auxiliary Steam Plant for Seattle, J. H. Longfellow. Jl. of Electricity, vol. 41, no. 4, Aug. 15, 1918, pp. 152-153. Fuel-oil operation with provision for change over to a coal-fired system in new 100,000-kw. installation.

Coal Selection

Coal and Its Selection, R. June. Brick & Clay Rec., vol. 53, no. 5, Aug. 27, 1918, pp. 389-392, 4 figs. Classification of coals; graphs showing relation of coal to combustion space, influence of moisture, and effect of ash on heating value of Illinois screenings. (Continuation of serial.)

Combustion Losses

Management of the Power Plant, Robert June. Textile World Jl., vol. 54, no. 10, Sept. 7, 1918, pp. 81-87, 2 figs. Combustion losses and how they may be reduced (Third of a series. First two in July 6 and Aug. 24 issues.)

Education of Firemen

Education of Boiler-Room Men Necessary, Edwin A. Hunger. Elec. World, vol. 72, no. 8, Aug. 24, 1918, pp. 344-347. Human element important factor in fuel-conservation efforts; means of fostering interest of firemen; notes on experience of several companies.

Fuel Conservation

Canadian Factory Reduced Coal Bill, B. K. Read. Can. Mfr., vol. 38, no. 9, Sept. 1918, pp. 23-27, 3 figs. Methods adopted and tables of tests on furnaces made by the Dominion Forge & Stamping Co. (To be concluded.)

Coal Conservation in Fact, C. R. Knowles. Contract Rec., vol. 32, no. 36, Sept. 4, 1918, pp. 719-720. Remarks on present waste.

Coal Conservation in New England, Ira N. Hollis. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 89-93. Outlines Massachusetts plan and scheme of organization to reach every factory and reduce and eliminate the present wastage of fuel.

Coal Saving by the Scientific Control of Steam Boiler Plants, D. Brownlie. Engineering, vol. 106, no. 2741, July 12, 1918, pp. 25-27. Average figures for 250 typical plants covering period from 1910 to the present, showing economy that can be effected by adoption of scientific methods in the boiler-house.

Coal Storage Conservation Rules, W. D. Langtry. Ice & Refrig., vol. 54, no. 5, May 1918, pp. 256-257. Oxidation in storage; action of pyrites; spontaneous heating; deterioration; avoiding dangers. Paper before Ill.-Wis. Ice Dealers' Assn.

Conservation of Fuel in California, R. J. C. Wood. Elec. World, vol. 72, no. 8, Aug. 24, 1918, pp. 348-350, 1 fig. By interconnection of systems with different load characteristics one company alone will save nearly a million barrels of fuel oil. Hydroelectric development must continue to meet growing demand for energy.

Fuel Conservation on the Santa Fe, Charles E. Parks. Ry. Rev., vol. 63, no. 4, July 27, 1918, pp. 124-125. Savings of upwards of $2,000,000 made in nine years by the present fuel organization of this road; methods used are explained.

Important Phases of the Fuel Conservation Problem, H. C. Woodbridge. Ry. Age, vol. 65, no. 8, Aug. 23, 1918, pp. 335-336. Suggestions to railway men of all departments regarding economical use of coal. Abstract of paper before Railway Club of Pittsburgh.

Methods for More Efficiently Utilizing Our Fuel Resources. Part XXI. The Coal Fields of the United States, Marius R. Campbell. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 602-619. Detailed statistics of available reserves, present production of each coal region, and map showing all known coal deposits and quality of coal in each region. Abstract from professional paper 100-A, U. S. Geol. Survey, 1917.

Methods for More Efficiently Utilizing Our Fuel Resources, R. H. Fernald. Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 542-555, 11 figs. Importance of fuel; statistics of world's coal supply and production; comparative heating values of coal; peat; petroleum and natural gas: conservation.

Reducing Water Waste to Save Coal. Mun. Jl., vol. 43, no. 7, Aug. 17, 1918, pp. 128-129. Figures derived from data obtained in cities of New York; ways by which water waste and leakage can be reduced.

Ways and Means of Saving Coal in the Boiler Room and Shop. Brick & Clay Rec., vol. 53, no. 4, Aug. 13, 1918, pp. 300-301. Recommendations of U. S. Fuel Administration concerning generation and use of power, light and heat.

Gas Fuel

Some Notes on Gas-Firing Boilers, T. M. Hunter. Proc. South Wales Inst. of Engrs., vol. 34, no. 2, July 19, 1918, pp 127-155, 4 figs. Dry and wet processes of gas cleaning; losses involved in boiler firing by gas; essentials for economical combustion and present methods of burning gas; conclusion drawn from a number of experiments upon a Lancashire boiler; tables showing results following upon the combustion of three typical gases, with different quantities of air dilution.

Kerosene

The Boiling Point of the Paraffins, G. le Bas. Chem. News, vol. 117, no. 3052, July 19, 1918, pp. 241-242. Table showing behavior of compounds in disagreement with Hinrichs-Newmann's rules correlating the boiling point and chemical constitution.

Low-Grade Fuels

Sawdust and Wood Burning. Power Plant Eng., vol. 22, no. 16, Aug. 15, 1918, pp. 647-654, 9 figs. A symposium dealing with furnace designs, conditions to maintain, conveying and storage systems, and value of sawdust and wood as fuels.

The Use of Lignite, Bagasse and Wood Waste for Power Generation and Other Purposes, John B. C. Kershaw. Engineer, vol. 126, no. 3267, Aug. 9, 1918, pp. 121-122, 3 figs. Chemical and physical properties of lignite; power generation from air-dried lignite; briquetting.

Oil Fuel

France and the Use of Petroleum, M. Henri Berenger. Petroleum Rev., vol. 39, nos. 833 and 834, July 6, and 13, 1918, pp. 11-12 and 27-28. Uses for heating engine boilers; liquid fuel in internal-combustion motors (Diesel type); international problem of petroleum and heavy oils. (Continued from vol. 38, p. 406.)

Petroleum from Coal. Petroleum Rev., vol. 39, no. 838, Aug. 10, 1918, p. 87. Report of committee of Technologists' Instn. on production of oil from cannel coal and allied minerals.

Petroleum Under the Microscope, James Scott. Petroleum World, vol. 15, no. 214, July 1918, pp. 282-283, 3 figs. Some unrefined compounds.

Supply of Oil Available from Shales, G. Egloff and J. C. Morrell. Oil & Gas Jl., vol. 17, nos. 11 and 12, Aug. 16 and 23, 1918, pp. 42-46 and 45-48. Treatment in retorts; comparative yields from oil shales; source of oil shale used; experimental methods; distillation analysis, aromatic hydrocarbons; analysis of water resulting from the thermal decomposition of the oil shale; phenols and its derivatives; heterocyclic nitrogen compounds; compounds isolated from oil-shale retorting.

Peat

Peat Occurrences in Illinois. Jl. Am. Peat Soc., vol. 11, no. 3, July 1918, pp. 148-152. Results obtained from the Manito (Mason Co.) experiment field on deep peat where treated plots and untreated strips were cropped. Suggestive treatments for different types of peat soils.

Possibilities of Using Peat as Fuel in Some Places. Jl. Am. Peat Soc., vol. 11, no. 3, July 1918, pp. 140-144. Fuel value and method of preparation. From U. S. Geol. Survey Press Bul., June 19, 1918.

Value of Peat Fuel for the Generation of Steam. Engineer, vol. 126, no. 3267, Aug. 9, 1918, pp. 123-124, 1 fig. Reprint of Bulletin No. 17, Canadian Department of Mines.

Pulverized Fuel

General Utilization of Pulverized Coal, Henry G. Barnhurst. Chem. Eng. & Min. Rev., vol. 10, no. 114, March 1918, pp. 174-177. Paper before Cleveland Eng. Soc.

Smokeless Combustion

Fuel Economy in the Operation of Hand Fired Power Plants. Contract Rec., vol. 32, no. 27, July 3, 1918, pp. 527-531, 4 figs. Chemical analysis of combustion and discussion of the fundamental conditions necessary for complete and smokeless combustion. From Univ. of Ill. Bul.

Smoke Prevention—Coal Saving Suggestions. Paper, vol. 22, no. 25, Aug. 28, 1918, p. 32. Brief outline of suggestions based on long experience of Westinghouse Elec. & Mfg. Co.'s combustion engineers.

Storage

Storage and Handling of Gas Coal, H. H. Stoek. Gas Age, vol. 42, no. 4, Aug. 15, 1918, pp. 145-149. Review of investigations by the Experiment Station of the University of Illinois. (To be continued.)

The Storage of Bituminous Coal, with Reference to its Liability to Spontaneous Combustion in Storage Heaps, Bunkers or Cargo. John H. Anderson, Trans. Inst. Marine Engrs., vol. 30, paper no. 236, June 1918, pp. 81-98 and discussion pp. 98-117. Record of methods employed, which so far have given satisfaction.

The Storage of Bituminous Coal, H. H. Stoek. Power Plant Eng., vol. 22, no. 15, Aug. 1, 1918, pp. 614-616, 3 figs. Abstract of paper before Western Soc. of Engrs.

Waste Heat

Waste Heat Utilization in Cement Works, H. D. Baylor. Ferro-Concrete, vol. 9, no. 12, June 1918, pp. 430-433, 2 figs. Data obtained with a boiler recently installed by the Louisville Cement Co. From paper before Am. Inst. of Chem. Engrs.

See also Chemical Technology (Oil Industry); Coal Industry.

FURNACES

Design

Development of Power from the Standpoint of the Boiler Room, C. F. Hirshfeld. Power, vol. 48, no. 8, Aug. 20, 1918, pp. 284-286, 2 figs. J. E. Alfred Lectures on Engineering Practice, Johns Hopkins University.

Graf Furnace

Graf Gas Consuming Furnace, John Nelson. Iron Age, vol. 102, no. 6, Aug. 8, 1918, p. 339, 1 fig. Air introduced above bridge wall burns gases ordinarily wasted in boilers.

Radiation Furnaces

Superficial Radiation Furnaces (Fours à radiation superficielle), M. P. Negrier. Revue de Métallurgie, year 15, no. 4, July-Aug. 1918, pp. 391-398, 4 figs. Combustion; scheme of burners and mixers; applications of superficial radiation.

Two-Zone Furnace

The Two-Zone Furnace, O. H. Hertel. Popular Engr., vol. 10, no. 1, July 1918, pp. 26-27. Features of the two zone boiler furnace.

See also Electrical Engineering (Furnaces); Foundry (Electric Brass Furnaces); Steel and Iron (Electric Furnace Melting).

HEATING

Condensation

Returning Condensation in High and Low-Pressure Heating Systems, Charles L. Hubbard. Domestic Eng., vol. 84, no. 7, Aug. 17, 1918, pp. 236-238, 6 figs. Notes on various methods of saving condensation. (Concluded.)

Hot-Water Heating

Expansion of Water in Hot Water Heating Systems, Howting. Plumbers' Trade Jl., vol. 65, no. 5, Sept. 1, 1918, pp. 277-279, 4 figs. Allowance for expansion in design, construction or installation.

Radiators

Meeting the High Cost of Heating and Ventilating Apparatus, George T. Mott. Heat. & Vent. Mag., vol. 15, no. 8, Aug. 1918, pp. 18-24, 3 figs. Advocates use of wall radiators rather than pipe coils as a matter of economy.

Room Temperature

A Study of Degrees of Discomfort. Heat. & Vent. Mag., vol. 15, no. 8, Aug. 1918, pp. 11-14, 1 fig. Based on temperature comfort tests made at Chicago Normal College by Prof. J. W. Shepherd.

School Buildings

School Building Heating and Ventilation, Samuel R. Lewis. Heat. & Vent. Mag., vol. 15, no. 8, Aug. 1918, pp. 29-35, 4 figs. First article of series.

HOISTING AND CONVEYING

Coal Handling

An Electrically Interlocked Car Haul and Car Feeder, R. P. Hines. Coal Age, vol. 14, no. 7, Aug. 15, 1918, pp. 300-302, 4 figs. A car feeder within the mine and a car haul leading to tipple are so connected electrically that feeder cannot be started until haul is running at normal speed. Both apparatus may be stopped at various points.

Effective System of Coal Handling at Providence, G. K. Jenckes. Gas Age, vol. 42, no. 4, Aug. 15, 1918, p. 158, 1 fig. Extension through use of locomotive crane.

The Britannia Colliery, Pengam, Mon., George Hann. Colliery Guardian, vol. 116, no. 3004, July 26, 1918, pp. 173-175, 2 figs. Illustrated description of plant and equipment; all haulage mechanical. From a paper before South Wales Inst. of Engrs.

Conveyors

Conveyors for Chemical Works, W. H. Atherton. Cassier's Eng. Monthly, vol. 54, no. 1, July 1918, Supp. pp. i-viii, 9 figs. Forms and sizes of oxide and coal conveyors. (Continuation of serial.)

Cranes

Large Navy Floating Crane Made Safe by Regenerative Braking. Elec. Contractor-Dealer, vol. 17, no. 11, Sept. 1918, pp. 100-101, 3 figs. Data of new giant crane said to have lifted a complete tugboat from its berth on the harbor bottom after sinking.

Wall Cranes, E. G. Beck. Mech. World, vol. 64, no. 1646, July 19, 1918, pp. 30-31, 4 figs. Mathematical analysis of a frame under specified loading. (Continuation of a serial; preceding article published May 24.)

Elevators

Factors Governing Elevator Drive, C. E. Clewell. Elec. World, vol. 72, no. 8, Aug. 24, 1918, pp. 340-343, 8 figs. Standard safety features usually embodied in control equipment; power requirements of elevators and types of motors suited to the service; direct and alternating—current elevator motors.

Lift Controllers

Lift Controllers and Controlling Gear for D. C. Lift. Electricity, vol. 32, no. 1445, July 19, 1918, pp. 381-382, 2 figs. Diagrams for car-switch and push-button control systems. (Continuation of serial.)

Marine Railway

Features of an Electrically Operated Marine Railway. Elec. Rev., vol. 73, no. 8, Aug. 24, 1918, pp. 290-292, 3 figs. Installation on Illinois River served by central-station company; boats carried through channel.

Overhead Carriers

Lifeboat Transporting and Lowering Gear. Shipping, vol. 4, no. 7, Aug. 17, 1918, pp. 13-14. Plan and elevations of Ross-Anderson device, consisting of a series of athwartship and fore-and-aft girders carried on columns and forming overhead tracks for trolleys with angular pull bearing.

Notes on the Overhead Koepe Winding Plant at Plenmeller Colliery, Haltwhistle, Northumberland, George Raw. Trans. Inst. Min. Engrs., vol. 55, part 3, July 1918, pp. 170-186, and (discussion), pp. 186-188, 9 figs. Study of operation of plant.

Ropeways

Ropeways in War Time, Telpher. Mech. World, vol. 63, no. 1612, June 21, 1918, pp. 295-296, 9 figs. Explanation of various forms and details of mono-cable and bi-cable lines.

Slag Haulage

Molten Slag Is Hauled by Rail for Making Embankments. Eng. News-Rec., vol. 81, no. 6, Aug. 8, 1918, pp. 267-268, 1 fig. Union Railroad at Pittsburgh handles hot materials in ladle cars; fills made in layers prove very substantial.

Trucks, Industrial

Karry-Lode Industrial Trucks, Tractors and Trailers. Automotive Industries, vol. 39, no. 6, Aug. 8, 1918, pp. 242-243, 3 figs. Trucks employ roller-pinion type of internal drive and are provided with automatic safety switch for use on steamship piers, in railway yards and industrial plants.

Transportation by Power Trucks, Reginald Trautschold. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 97-101, 7 figs. Features of a number of types of special trucks for mechanical handling of materials, with paragraphs on operating costs.

Turntables

Bronze Turntable and Movable Bridge Discs, O. E. Selby. Foundry, vol. 46, no. 312, Aug. 1918, pp. 368-371. Existing specifications discussed and changes recommended to users and brass foundrymen.

Wire Ropes

Wire Ropes, "Kinetics." Practical Engr., vol. 58, no. 1638, July 18, 1918, pp. 28-29, 4 figs. Details of construction of guide, rubber and sinking ropes; winding speeds; factors of safety. (Previous articles published Jan. 3, Feb. 14, Mar. 28, May 2 and June 20.)

See also Transportation (Marine Terminals.)

HYDRAULICS

Bazin Weir Formula

Verification of the Bazin Weir Formula by Hydro-Chemical Gaugings, C. Herschel. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 835-842. Discussion of F. A. Nagler's paper.

Caissons, Concrete

Concrete Caisson of New Type Used in Breakwater. Eng. News-Rec., vol. 81, no. 6, Aug. 8, 1918, pp. 258-260, 5 figs. Trapezoidal shape adopted for economy; caissons launched, sunk in place and filled to carry monolithic concrete superstructure.

Cast-Iron Linings of Wells

Special Cast Iron Lining of Two Large Bore Wells, W. H. Maxwell. Eng. & Contracting, vol. 50, no. 7, Aug. 14, 1918, pp. 172-175, 3 figs. Reprint from Water and Engineering, London.

Dams

Facing Leaky Rock-Fill Dam with Timber Planks, George M. Bull. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, pp. 229-231, 2 figs. After dam was raised 25 ft., old concrete facing leaked, so 3 rows of creosoted boards were placed on face.

Improving Arch Action in Arch Dams, W. P. Creager and S. H. Woodward. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 871-873. Discussion of L. R. Jorgensen's paper in May issue.

Drainage Channels

Keeping Land Drainage Channels Clear of Growth and Debris in the South, Albert S. Fry. Eng. News-Rec., vol. 81, no. 6, Aug. 8, 1918, pp. 263-266. Experiences in removal of willow and other sprouts and maintaining cross-section in two drainage districts; cost data given.

Flood Control

Detention Reservoirs with Spillway Outlets as an Agency in Flood Control, I. E. Houk and K. C. Grant. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 827-834, 3 figs. Discussion of paper by the late H. M. Chittenden.

Friction in Pipes

Water Friction in Pipes and Elbows, E. H. Peterson. Ice & Refrig., vol. 54, no. 5, May 1918, pp. 274-275, 2 figs. Charts showing for different sizes the friction loss in pounds per square inch for various capacities in gallons of water per minute.

Ice Diversion

Ice Diversion, Hydraulic Models, and Hydraulic Similarity, E. E. R. Tratman and B. F. Groat. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 797-822, 3 figs. Theory of hydraulic models; theory of dynamic similarity; factors of safety. Discussion of B. F. Groat's paper.

Hydroelectric Installations

Hydroelectric Development at Rochester, N. Y. Street Ry. Bul., vol. 18, no. 8, Aug. 1918, pp. 349-351, 7 figs. New 25,000-kva. station of the Railway and Light Co., located in the gorge of the Genesee River.

Junction Development Power Plant. Power, vol. 48, no. 8, Aug. 20, 1918, pp. 258-262 6 figs. Description of 16,500-kw. hydroelectric plant supplying Grand Rapids.

New Plant Added to Michigan System. Elec. World, vol. 72, no. 6, Aug. 10, 1918, pp. 244-248, 6 figs. Description of junction development, the largest hydro-electric plant in Michigan, which is connected with Grand Rapids by 140,000-volt line.

Interesting Small-Capacity Low-Head Hydroelectric Development. Elec. Rev., vol. 73, no. 5, Aug. 3, 1918, pp. 158-160, 5 figs. Description of Geddes plant of 1000-kw. capacity operating under a working head of 15 ft.

The New Copco Development, C. B. Merrick. Jl. of Electricity, vol. 41, no. 4, Aug. 15, 1918, pp. 150-152. Features of construction and operation of hydroelectric plant at Copco, Cal.

The New 300,000-Hp. Hydro Development. Elec. News, vol. 27, no. 13, July 1, 1918, pp. 36-38, 2 figs. Layout of scheme and cross-section of development works at power house of Chippawa plant, Niagara Falls, Ont.

Shutting Off Water

Possiblities of Shutting Off Water, M. A. LaVelle. Gas & Oil Jl., vol. 17, no. 8, July 26, 1918, pp. 48-50. Facts on shutting off bottom water by cement in Kansas and Oklahoma wells; use of cement and importance of excluding water from oil wells.

Silt Deposits

Calculating and Preventing Silt Deposits in Reservoirs, F. Drouhet. Contract Rec., vol. 32, no. 27, July 3, 1918, pp. 522-523. Results obtained in Switzerland from a study of the geographic and hydraulic conditions of water courses.

Storage Reservoirs

Determining the Regulating Effect of a Storage Reservoir, Robert E. Horton. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 455-458, 3 figs. Differential equation for inflow, outflow and storage relations solved by using time interval as independent variable.

Water Works

American Army's Water Works Projects in France Number About Four Hundred, Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 434-437, 5 figs. Great range in size and character of supply; several mechanical filters under way; laboratory division controls quality of water.

Construction of Collection and Transmission System for Marin Municipal Water District. Western Eng., vol. 9, no. 9, Sept. 1918, pp. 355-365, 10 figs. Work done in Marin Co., Cal., containing six towns; system consists mainly of two storage reservoirs with a total capacity of 380,000,000 gal.

Effect of War Conditions Upon Construction, Operaton and Maintenance of Water Works. Eng. & Contracting, vol. 50, no. 7, Aug. 14, 1918, pp. 176-177. Findings of special committee of Am. Water Works Assn., with data obtained from about 50 municipally and corporately owned water works in the United States.

Plant Extensions of Public Utilities Financially Considered, John W. Ledoux. Jl. Engrs. Club of Phila., vol. 35-37, no. 164, July 1918, pp. 337-338. Suggestions regarding waterworks extensions.

Rural Community Water Supplies, E. L. Miles. Jl. Eng. Inst. of Canada, vol. 1, no. 4, Aug. 1918, pp. 145-150, 3 figs. Account of author's observations while acting as government inspector of water supplies in Province of Saskatchewan. Also published in Can. Engr., vol. 35, no. 7, Aug. 15, 1918, pp. 161-164 and 166, 3 figs. Before Second General Meeting of Eng. Inst. of Can.

The Water Supply of New York. Engineer, vol. 126, 3267, Aug. 9, 1918, pp. 109-111, 8 figs. Engineering features of dams, tunnels, aqueducts, etc.

War Burdens of Water-Works of United States Increase. Eng. News-Rec., vol. 81, no. 7, Aug. 15, 1918, pp. 308-312, 3 figs. From a report to executive committee of Am. Water-Works Assn.

Water-Works Operation. Min. Jl., vol. 45, nos. 6, and 7, Aug. 10 and 17, 1918, pp. 107-108 and 111 and 129-130. Repairing leaks and breaks in water mains and underground appurtenances; preventing recurrence of leaks; leaking valves.

INDUSTRIAL ORGANIZATION

Cost of Service the Chief Factor in Rate Regulation, William G. Raymond. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 451-454. Rational "fair value" held to be sum of interest on investment and profit on operating expenses, capitalized at "fair return" rate.

Elimination of Idleness by Systematic Study, Charles Whiting Baker. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 450-451. Graphic chart shows significance of increase in efficiency by reducing machinery idleness among industries.

Organization and Coöperation. David J. Champion. Boiler Maker, vol. 18, no. 8, Aug. 1918, pp. 229-231. Trade organization necessary for progress; closer coöperation among boiler manufacturers badly needed. Address before annual convention, Boiler Manufacturers' Assn.

Capital Charges

Discussion of Mr. David M. Mowat's Paper on "Capital Charges Considered along with Current Expenses." Trans. Inst. Min. Engrs., vol. 55, part 3, July 1918, pp. 190-195. Paper appeared in Trans. 1917-1918, vol. 54, p. 317 and vol. 55, pp. 54-133.

City War Organization

Milwaukee's Organization for War, Willits Pollock. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 121-123. Trying out general staff idea in an industrial city.

Demobilization

Contract Prices During Demobilization, W. P. Digby. Elecn., vol. 81, no. 2099, Aug. 9, 1918, pp. 308-309, 4 figs. Abstract of paper before Inst. Elec. Engrs. Experience of previous wars; increase in wages and prices of materials in the past few years.

Depreciation

Some Pitfalls in Regulating Depreciation, John Bauer. Elec. Ry. Jl., vol. 52, no. 8, Aug. 24, 1918, pp. 326-328.

See also Factory Management.

INTERNAL-COMBUSTION ENGINEERING

Carburetors

Four New Carburetion Devices. Motor Age, vol. 34, no. 6, Aug. 8, 1918, pp. 40-42, 6 figs. Universal Airgas, Manifold, Hodges and Kerosene Equipment, with their characteristics.

The Carburettor. Technicus. Auto, vol. 33, no. 30, July 26, 1918, pp. 532-534, 2 figs. Technical study of the factors determining its successful operation. (Concluded from p. 516.)

Diesel Engines

Operation of Submarine Diesel Engines, F. C. Sherman. Gas Eng., vol. 20, no. 9, Sept. 1918, pp. 425-429. Causes of troubles and their elimination.

Random Remarks on Modern Marine Diesel-Engines, H. R. Setz. Motorship, vol. 3, no. 9, Sept. 1918, pp. 10-12, 7 figs. Effect of length of stroke on efficiency; distinction between mechanical and physical strokes; technical details of the new Tosi merchant-marine Diesel engine.

Heavy-Oil Engines

The Heavy-Oil Engine, Charles E. Lucke. Engineer, vol. 126, no. 3265, July 26, 1918, pp. 80-83. Its application; tendencies in design. From paper before Engrs. Club of Phila., Jan. 1918, and printed in Journal of Club, June, 1918.

High-Speed Engines

High-Speed Internal Combustion Engines. Harry R. Ricardo. Mech. World, vols. 63 and 64, nos. 1646 and 1647, June 14 and July 26, 1918, p. 284 and pp. 45-46, 1 fig. Features of high-speed engine design. From paper before North-East Coast Inst. of Engrs. and Shipbuilders. (To be continued.)

Ignition System

A Simple Dual Ignition System, G. F. Crouch. Motor Boat, vol. 15, no. 15, Aug. 10, 1918, pp. 22-23, 2 figs. Switch invented by E. S. Brainard, Sacramento, Cal., to use battery and coil with high-tension magneto.

Individual Types

Buda Model "H T U" Engine. Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, pp. 282-283, 5 figs. Model with detachable cylinder head, force-feed lubrication, special crankcase construction, heavier flywheel for tractor use, and vaporizing manifold for burning kerosene, designed for truck and tractor service.

Kahlenburg Heavy-Oil Engine. Motorship, vol. 3, no. 9, Sept. 1918, p. 13, 1 fig. General features of motor of the surface-ignition class built at Two Rivers, Wis.

The Possibilities of the Hvid Engine. Nat. Gas Engine Assn. Bul., vol. 4, no. 2, Sept. 1918, pp. 6-17. Discussion of paper by E. B. Blakely, published in Aug. Bulletin.

Knocking

Knocking in Gas Engines. Practical Engr., vol. 58, no. 1638, July 18, 1918, pp. 31-32. Significance and possible causes.

Multiple Valves

Increasing the Engine's Volumetric Efficiency, Morris A. Hill. Automotive Eng., vol. 3, no. 7, Aug. 1918, pp. 295-297, 5 figs. Further comment on multiple valves, and designs which aim to give multiple-valve effect without its numerous parts. (Fifth of series.)

Pulverizers

Oil-Engine Sprayers or Pulverizers, A. H. Goldingham and C. T. O'Brien. Motorship, vol. 3, no. 9, Sept. 1918, pp. 19-20, 4 figs. Description of four types. (Continued.)

Sub-Pistons

Gile Engine Employs Sub-Piston. Automotive Industries, vol. 39, no. 6, Aug. 8, 1918, pp. 229 and 238, 2 figs. Longitudinal and cross-sections of engine designed to work on two-stroke principle, with piston-controlled port for inlet and a poppet valve in the head for exhaust.

Turbines

Internal Combustion Turbines. Practical Engr., vol. 58, no. 1639, July 25, 1918, pp. 40-42, 10 figs. Some types of gas turbines.

See also Aeronautics (Engine Pistons, Engine Temperature Control, Engines, Mufflers); Motor-Car Engineering (Piston Displacement); Producer Gas and Gas Producers.

IRON

(See Steel and Iron)

LABOR

Bethlehem Award

Labor Board's Award in Bethlehem Case. Iron Age, vol. 102, no. 6, Aug. 8, 1918, pp. 326-327. Text of finding in case of machinists and electrical workers vs. Bethlehem Steel Co.

Business Management

Significant Changes in Business Management. Am. Mach., vol. 49, no. 5, Aug. 1, 1918, pp. 191-193. Suggestions regarding policy to meet changes in relations between capital and labor.

Housing

Company Residences for Railroad Employees, C. B. & Q. R. R. Ry. Rev., vol. 63, no 6, Aug. 10, 1918, pp. 197-200, 6 figs. Description with plans of cottages and rooming houses.

Labor Costs

Report on Estimating Labor Costs. Elec. Rev., vol. 73, no. 4, July 27, 1918, pp. 125-131, 7 figs. Compiled by the Electrical Estimators' Assn. of Chicago and presented at the Cleveland Convention of the National Assn. of Electrical Contractors and Dealers.

Negroes

Negroes a Source of Industrial Labor, Dwight Thompson Farnham. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 123-129, 10 figs. Experiences of author with this type of labor.

Piecework Rates

Determining of Piecework Rates from Charts, Otto M. Burkhardt. Am. Mach., vol. 49, no. 9, Aug. 29, 1918, pp. 383-387, 6 charts. A simple method of figuring piecework prices by means of charts when the necessary time elements are known.

Railroad Employees

Classification, Working Conditions and Wages of Mechanical Department Employees. Ry. Rev., vol. 63, no. 5, Aug. 3, 1918, pp. 154-157. Supplement no. 4 to general order no. 27, Director General of Railroads.

Training

Intensive Training in an Aircraft Plant, Frank L. Glynn. Automotive Industries, vol. 39, no. 9, Aug. 29, 1918, 7 figs. Curtiss Co.'s school has capacity of 200 to 300 operatives per week. Women develop skill after short instruction period.

Steel Plant Educates Foreign Employees. Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 384-385. Youngstown Sheet & Tube Co. establishes system of free schools primarily for educating and Americanizing foreign-born employees in all parts of the mills.

The Training of Engineers, E. J. Silcock. Can Engr., vol. 35, nos. 6 and 7, Aug. 8 and 15, 1918, pp. 138-140 and p. 150. Scope of education of civil engineer and amount of specialization necessary for those who intend to practice as water-works engineers. Paper before Inst. Water Engrs., England. Published also in Surveyor, vol. 54, no. 1381, July 5, 1918, pp. 3-4.

Training Metallurgists in Schools and Metallurgical Works, H. C. H. Carpenter. Can. Min. Jl., vol. 39, no. 14, July 15, 1918, pp. 246-248. Extracts from presidential address, Inst. of Metals, London, March 1918.

Training 150 Operators Per Week. Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, pp. 277-280. How the vestibule school of Remington Arms Company is meeting the demand for skilled workers of both sexes; how operatives are routed through plant.

Women

Employment of Women in Munition Factories. Jl. Inst. Mech. Engrs., no. 5, June 1918, pp. 223-238. Records of several plants presented by members of Institute.

The Efficient Utilization of Labor in Engineering Factories, B. H. Morgan. Jl. Inst. Mech. Engrs., no. 5, June 1918, pp. 239-265. Special reference to women's work.

Women in Railway Work. Ry. Rev., vol. 63, no. 4, July 27, 1918, pp. 122-123, 4 figs. Women employed by railways in various capacities.

See also Coal Industry (Labor Situation.)

LIGHTING (ILLUMINATION)

Automobile Plants

Improved Lighting of Automobile Manufacturing Plants, F. H. Bernhard. Elec. Rev., vol. 73, no. 6, Aug. 10, 1918, pp. 205-211, 12 figs. Advisability of utilizing latest lighting developments; features that need special improvement.

Edison Lamps

Edison Mazda Lamps for Protective Lighting. Edison Lamp Wks. of Gen. Elec. Co., Bul. no. 43,412, July 1918, pp. 1-14, 26 figs. Application of contrast to protective lighting; glare; available apparatus; sketches illustrating arrangement in various systems.

Illumination

Fundamentals of Illumination Design, Ward Harrison. Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 535-541, 10 figs. Solution of problems covering the lighting requirements of a large general office, the main floor of a clothing store, a furniture factory, and an industrial plant manufacturing tools and other similar metal parts. (Concluded.)

Indirect Lighting

Illumination, Harold W. Brown. Elec. Contractor-Dealer, vol 17, no. 11, Sept. 1918, pp. 86-91, 23 figs. Applications of indirect lighting to hospitals, churches, reading rooms, stores and houses.

Laws on Lighting

Laws Regulating Insufficient Lighting, Chesla C. Sherlock. Am. Mach., vol. 49, no. 9, Aug. 29, 1918, pp. 381-382. Résumé of some court findings.

Printing Plants

The Lighting of Printing and Book-Binding Plants, F. H. Bernhard. Elec. Rev., vol. 73, no. 8, Aug. 24, 1918, pp. 279-286, 11 figs. Importance of best possible lighting to printer; general features of lighting problem and suggestions for effective illumination of principal departments.

War Conservation

Lighting Curtailment, Preston S. Miller. Jl. Engrs.' Club, Phila., vol. 35-8, no. 165, Aug. 1918, pp. 381-391 and (discussion) pp. 391-399, 2 figs. Considers that since coal used in production of electric light is less than 2 per cent of total output of country and standards of illumination intensity before the war were in general too low, it is practicable to effect much larger savings by other methods with less disadvantage to the public.

War Conservation of Power and Light, Chas. E. Stuart. Jl. Engrs.' Club, Phila.,

vol. 35-8, no. 165, Aug. 1918, pp. 400-403. Practical scheme of operations of power and light division of U. S. Fuel Administration.

See also Electrical Engineering (Lamps.)

LUBRICATION

Selection

Important Factors in Choosing Lubrichants, F. H. Conradson. Petroleum Rev., vol. 39, no. 838, Aug. 10, 1918, pp. 85-86. Lubrication problems in connection with new designs, service conditions and requirements.

See also Air Machinery (Lubrication); Steam Engineering (Lubrication, Engine Cylinder); Testing and Measurements (Lubricants Testing, Viscosimeter.)

MACHINE PARTS

Ball Bearings

Ball Bearings for Machine Shop Equipment, Edward K. Hammond. Machy., vol. 24, no. 12, Aug. 1918, pp. 1097-1103, 6 figs. Discusses the advantages of ball bearings, their construction, lubrication, design of mountings and felt packings.

Ball-Races in Machine Tools, J. Horner. Mech. World, vol. 64, no. 1646, July 19, 1918, pp. 26-27, 6 figs. Application of Skefko ball bearings to various machines. (Continuation of a serial; preceding article published June 28.)

Belts

Belts for Driving High-Speed Cutterheads. Wood-Worker, vol. 37, no. 6, Aug. 1918, pp. 40-41, 2 figs. Suggestions recommending light double belts for this service.

Cam Profiles

Cam Profiles (I). W. K. Wilson. Mech. World, vol. 64, no. 1647, July 26, 1918, pp. 43-44, 3 figs. Investigation of effect a modification of cam profile can produce upon inertia pressure to which valve gear is subject. (To be continued.)

Gears

A Note on Spiral Gears. Mech. World, vol. 64, no. 1647, July 26, 1918, p. 39, 1 fig. Suggestions in calculation of engine gears.

Gear Standardization, B. F. Waterman. Machy. Market, nos. 926 and 927, Aug. 2 and 9, 1918, pp. 17 and 19. General aspect of the problem; application of standards, worm making; inspection committee. Abstract of paper before Am. Gear Mfrs.' Assn.

Strength of Spiral Type Bevel Gears, Reginald Trautschold. Mach., vol. 24, no. 12, Aug. 1918, pp. 1111-1115, 2 figs. Formulæ for determining strength of spiral type bevel gears.

Thermal Refinement of Gear Blanks, C. R. Poole. Page's Eng. Weekly, vol. 33, no. 724, July 26, 1918, p. 41. Difference between carbonized and heat-treated types of gears. Paper before Am. Gear Mfrs.' Assn.

MACHINE SHOP

Balancing

Dynamic Balancing of Rotating Sections, Carl Hering. Elec. World, vol. 72, no. 9, Aug. 31, 1918, pp. 389-390, 1 fig. Dynamic balancing additional to static balance; rational unit for expressing and measuring the tolerance allowed.

Blacksmith Shop

The Engineer's Smith, Joseph Horner. Mech. World, vol. 63, no. 1642, June 21, 1918, p. 294, 2 figs. Character of the layout, and nature of the practice of present day shops. (To be continued.)

Bolt Making

Bolt Manufacture in Railway Shops, M. H. Williams. Ry. Mech., Eng., vol. 92, no. 8, Aug. 1918, pp. 465-470, 7 figs. Consideration of methods and tools necessary for rapid production.

Chatter Marks

Elimination of Chatter Marks from Machined Work. Am. Mach., vol. 49, no. 8, Aug. 22, 1918, pp. 349-354, 11 figs. Some of the main causes of chatter marks and means taken to eliminate them.

Crank Repairs

Crank Repairs, C. E. Anderson. Power Plant Eng., vol. 22, no. 16, Aug. 15, 1918, pp. 667-669, 4 figs. Difficulties encountered and remedies employed.

Cutting of Metal

Cutting Heavy Forging Ingots, W. B. Perdue. Jl. Acetylene Welding, vol. 2, no. 2, Aug. 1918, pp. 80-86, 2 figs. Methods used by Judson Mfg. Co., Oakland, Cal.

The Cutting of Cast Iron with Oxygen. Acetylene & Welding Jl., vol. 15, no. 177, June 1918, pp. 106-109, 2 figs. Table of data and results from a series of tests. (Concluded.)

The Cutting of Iron and Steel by Oxygen, M. R. Amedeo (Translated from original French by D. Richardson). Acetylene & Welding Jl., vol. 15, no. 177, June 1918, pp. 102-105, 3 figs. Microphotographs showing decarbonization of metal with central jet oxy-acetylene cutting blowpipe. (Continuation of serial.)

Drilling-Machine Work

Unusual Operations on Drilling Machines, Edward K. Hammond. Machy., vol. 24, no. 12, Aug. 1918, pp. 1091-1093, 6 figs. Use of drilling machines for milling, broaching, driving studs and assembling.

Foil Manufacture

The Manufacture of Tin and Lead Foil, L. J. Krom. Metal Indns., vol. 16, no. 8, Aug. 1918, pp. 352-354, 7 figs. Brief illustrated description of process.

Friction Clutch

Manufacturing the Johnson Friction Clutch. Am. Mach., vol. 49, no. 6, Aug. 8, 1918, pp. 263-266, 11 figs. Details of manufacturing operations.

Gages

Flush-Pin Versus Limit Gages, Albert H. Dowd. Am. Mach., vol. 49, no. 7, Aug. 15, 1918, pp. 283-284, 5 figs. Describes several types of flush pin gages both for work and inspection and gives examples of their use.

Indicating Fixtures for the Gaging of Automobile Parts, Albert A. Dowd. Am. Mach., vol. 49, no. 7, Aug. 15, 1918, pp. 299-302, 5 figs. Description of several indicating gages.

Surface Gage with Fine Adjustments, J. G. J. Mech. World, vol. 64, no. 1646, July 19, 1918, p. 27, 1 fig. Sketch of a surface gage with adjustment for height.

Galvanizing Sheets

Modern Practice in Galvanizing Sheets, Clement F. Poppleton. Iron Age, vol. 102, no. 8, Aug. 22, 1918, pp. 433-436, 2 figs. Methods of constructing and operating galvanizing pots; preparation of material and costs; some hitherto unpublished facts.

Gas-Engine Construction

Gas Engine Work on the Pacific Coast, Frank A. Stanley. Am. Mach., vol. 49, no. 8, Aug. 22, 1918, pp. 343-347, 17 figs. Description of certain operations in making marine and stationary engines.

Machining Pistons, Flywheels and Cylinders of Gasoline Engines, M. E. Hoag. Am. Mach., vol. 49, no. 10, Sept. 5, 1918, pp. 443-444, 5 figs. Work of Potter & Johnson automatics with special fixtures and tooling.

Heat Treatment

Effect of Mass on Heat Treatment, E. F. Law. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 16, 15 pp., 17 figs. Report of experiments: Sets of heating and cooling curves of 18-in. cubes, each weighing 1¾ cwts., heated to a temperature of 1650 deg. fahr. and allowed to remain in the furnace for 4½ hr.; microphotographs of sections cut from test-pieces representing the steel cube from outside to center; survey of results obtained by other investigators; conclusions and further experiments on 12-in. cubes.

Electric Furnace for Heat Treating Small Airplane Parts, Dwight D. Miller. Am. Mach. vol. 49, no. 9, Aug. 29, 1918, pp. 373-376, 2 figs. Description of electric furnace for heat treating metal parts and operations involved.

Electric Treatment of Airplane Forgings, Dwight D. Miller. Iron Age, vol. 102, no. 7, Aug. 15, 1918, pp. 381-385, 4 figs. Details of Bailey furnace for heat treating axle forgings at plant of Ingalls-Shepard Forging Co.

Time Effect in Tempering Steel, A. E. Bellis. Ry. Jl., vol. 24, no. 8, Aug. 1918, pp. 27-28. Report of tests made on rifle-barrel steel. Abstract of A. I. M. E. paper.

Hobbing

Charts Giving Time Required to Hob Spur Gears, V. P. Rumley. Machy., vol. 24, no. 12, Aug. 1918, pp. 1085-1086, 2 charts.

Hobs and Hobbing, F. G. Hoffman. Mech. World, vol. 64, no. 1646, July 19, 1918, pp. 27-28. Proposed ideal system of cutting gears developed from a study of the various methods in use at present. Am. Gear Mfrs. Assn. paper.

Reclamation Work

Connecticut Company Centralizes Reclamation Work at New Haven. Elec. Ry. Jl., vol. 52, no. 9, Aug. 31, 1918, pp. 364-367, 14 figs. By segregating heavy repairs, manufacturing operations and reclaiming of damaged equipment this company has achieved substantial economies.

Rubber Insulators

Moulds for Hard Rubber Insulators, Effero. India-Rubber Jl., vol. 56, nos. 1, 2 and 3, July 6, 13 and 20, 1918, pp. 9-10, 33-34, 16 figs, and 57-61, 8 figs. Design features of the rotating distributor arm and stationary carbon holder for the high tension magneto. (Serial.)

Sand Blast

Sand-Blast Operation, D. Evans. Mech. World, vol. 64, no. 1646, July 19, 1918, p. 32, 4 figs. Pressure required for cleaning steel; description of four types of sand-blast equipment. (To be continued.)

Screw Cutting

Cutting and Verifying Accurate Screw Threads (La taille et la correction des vis de précision), Génie Civil, vol. 73, no. 5, Aug. 3, 1918, pp. 81-84, 10 figs. Bryant Symons screw-cutting lathe.

Screw-Cutting Simply Explained for Munition Workers, G. Gentry. Model Engr. & Elecn., vol. 39, no. 899, July 18, 1918, pp. 37-38. Calculating wheels for cutting metric threads on metric lathes and on English lathes. (Continuation of serial.)

Shafting Brackets

Hanger and Bracket Fixings for Rolled-Steel Joists, F. R. Parsons. Mech. World, vol. 64, no. 1646, July 19, 1918, p. 31, 9 figs. Suggested methods of attaching shafting brackets, hangers, bearings, idler or gallows pulleys to rolled-steel joists, in such a manner as will permit a certain amount of latitude of adjustment in order to bring them and the shafting into alignment.

Welding

A. C. Arc Welding and Cutting. Automotive Industries, vol. 39, no. 6, Aug. 8, 1918, p. 241, 1 fig. Light-weight machine of Electric Arc Cutting & Welding Co., Newark, N. J., consisting of a special transformer with no moving parts.

Bibliography of Electric Welding, 1918-1914, William F. Jacob. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 652-658. Includes references to theory, various uses, methods of application, and costs.

Boiler Repairs by Electric Welding, R. S. Kennedy. Boiler Maker, vol. 18, no. 8, Aug. 1918, pp. 225-227. Development of arc-welding process; description of equipment; examples of application of process to boiler repairs. From paper before Inst. of Marine Engrs., London.

Electric Arc Welding, A. M. Candy. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 9, Sept. 1918, pp. 1159-1171, 21 figs. History of process; present practice; manipulation of arc and weld; carbon vs. metallic electrodes.

My Method of Welding with the Electric Arc and Work Which I Have Done, E. D. Johnson. Boiler Maker, vol. 18, no. 8, Aug. 1918, pp. 219-222, 14 figs. Suggestions from author's nine years' experience.

The Autogenous Welding of Lead (Lead Burning), P. Rosenberg. Acetylene & Welding Jl., vol. 15, no. 177, June 1918, pp. 100-101, 5 figs. History of the manufacture of sulphuric acid and of autogenous welding. Enumeration of four processes for lead: hydrogen and air, hydrogen and oxygen, acetylene and air, acetylene and oxygen. (To be continued.)

The Relation to Welding Problems of the Properties of Iron and Steel and Their Heat Treatment. Jl. Acetylene Welding, vol. 2, no. 2, Aug. 1918, pp. 74-76. Difficulties in welding cast iron and suggested remedies to overcome them. (Continuation of serial.)

Welded Seams and Connections Correct Faults in Big Converters. Jl. Acetylene Welding, vol. 2, no. 2, Aug. 1918, pp. 70-73, 9 figs. Details of operation in welding a flange to a cotton converter.

Welding Methods at Columbus Shop. Ry. Mech. Eng., vol. 92, no. 8, Aug. 1918, pp. 473-474, 4 figs. Carbon- and metallic-arc welding both used; special building erected for welding.

Welding Truck Side Frames, Bolsters and Arch Bars. Ry. Jl., vol. 24, no. 8, Aug. 1918, pp. 23-24. Committee report before M. C. B. Assn.

MACHINERY

(See Metal-Working Machines, Woodworking Machines.)

MARINE ENGINEERING

Concrete Ships

Concrete Barges. Louis L. Brown. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 450-452, 8 figs. Brief description of design, method of construction, materials used, method of waterproofing and launching. From a paper before Am. Concrete Inst., June 1918.

Concrete Barges Designed for New York State Barge Canal. Eng. News-Rec., vol. 81, no. 6, Aug. 8, 1918, pp. 271-272, 4 figs. Shipping Board prepares plans for 500-ton towboats to be operated by Federal Railroad Administration.

Concrete Ship of 3500 Tons Deadweight Designed by Emergency Fleet Corporation. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 446-449, 9 figs. Conclusions of the Concrete Ship Department; details of the standard ship.

Design and Construction of Self-Propelled Reinforced Concrete Seagoing Cargo Steamers Now Building in Great Britain, T. G. Owens Thurston. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 455-464, 15 figs. Paper before Inst. of Naval Architects, London, March 1918.

Progress in the Application of Concrete to Barge and Shipbuilding, J. E. Freeman. Jl. West. Soc. Engrs., vol. 23, no. 3, Mar. 1918, pp. 205-220. Review of progress in concrete-boat building from its earliest inception; discussion of various problems entering into application of reinforced concrete to such construction.

Reinforced Concrete Tugs (Les remorqueurs en béton armé), G. Espitallier. Génie Civil, vol. 73, no. 4, July 27, 1918, pp. 61-64, 14 figs. Type Pelnard-Considère, Caquot & Co.; principles for computation of dimensions; protection; prevention of leaks.

Seagoing Reinforced Concrete Ships Sogaaende Jaernbetonskine), H. Glysing. Ingenioren, vol. 27, no. 58, July 20, 1918, pp. 413-415.

The Building of a Concrete Barge, L. L. Livingston. Contract Rec., vol. 32, no. 32, Aug. 7, 1918, pp. 629-630. Method recently employed at New York. Read before the Am. Concrete Inst.

The Building of Concrete Ships. Contract Rec., vol. 32, no. 33, Aug. 14, 1918, pp. 645-647. Am. Concrete Inst. paper.

The Design of Concrete Ships, H. Devereux. Western Eng., vol. 9, no. 9, Sept. 1918, pp. 343-358, 27 figs. Formulæ and curves.

Control Mechanism

Mechanical Interlock Between Telegraph and Main Engine Control Lever. Shipbuilding and Shipping Rec., vol. 12, no. 4, July 25, 1918, pp. 83-84, 1 fig. Mechanism to prevent the engine-control lever being moved in contradiction to the telegraph indications.

Corrosion

Corrosion of Ships. Nautical Gaz., vol. 94, no. 8, Aug. 24, 1918, p. 89. Causes and protectors. From Liverpool Jl. of Commerce.

Deadrise Cruisers

Model Experiments on Express Cruisers of Deadrise Type, T. A. Gamon. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 473-476, 7 figs. For high-speed length ratio, deadrise type proves superior to round bilge model; resistance of appendages investigated.

Electric Fittings

Construction and Uses of Marine Electrical Fittings. Elec. Rec., vol. 24, no. 3, Sept. 1918, pp. 61-66, 25 figs. Details of fittings and illustrations of typical, special and standardized types.

Furness Company's Shipyard

A New Furness Shipyard. Engineering, vol. 106, no. 2743, July 26, 1918, p. 82, 9 figs. Short notice of new enterprise, with illustrations of the work in progress. Also published in Engineer, vol. 26, no. 3265, July 26, 1918, pp. 73-74, 7 figs.

Hog Island

A Record of Achievements at Hog Island, W. H. Blood, Jr. Elec. Rev., vol. 73, no. 5, Aug. 3, 1918, pp. 155-157, 4 figs. Statistics on the work in progress and results already secured.

Launching

End-Launching of Vessel in Narrow Stream, Max Hausen. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 469-470, 1 fig. Vessel started down ways at high velocity and brought to a standstill at end of ways by means of a brake.

Motorships

Novel Large Britsh "Diesel"-Driven Tanker. Motorship, vol. 3, no. 9, Sept. 1918, pp. 14-15, 2 figs. General dimensions of Santa Margharita, a motorship of 11,000 tons d-w-c., fitted with solid-injection Vickers oil engines of 2500 b.hp. and with auxiliary motors of 1150 b.hp.

The Australian Motorship "Cethana." Motorship, vol. 3, no. 9, Sept. 1918, p. 15. Details of acceptance trials of American-built Diesel-engined wooden merchant vessel of the single well-deck type.

Trials of M. S. "Alabama." Motorship, vol. 3, no 9, Sept. 1918, p. 21. Speed tests of new 1000-b.hp. Diesel-driven vessel of 4000 tons deadweight capacity.

Repairs

Emergency Repairs to a Battleship. Shipbuilding & Shipping Rec., vol. 12, no. 5, Aug. 1, 1918, pp. 113-115. Details of work involved in substitution by the engine-room staff of the "Arkansas," of an electric motor for the wrecked starboard main circulating pump.

Reversing Rudders

Reversing and Control Rudder. The Rudder, vol. 34, no. 9, Sept. 1918, pp. 436-437, 7 figs. Experiments with a 25-ft. power boat showing the possibility of eliminating reversing turbines from turbine-propelled ships.

Rivetless Ship

See Welded Ships, below.

Submarines

Propelling Machinery for Submarine Boats (in Japanese), Genjiro Hamabe. Jl. Soc. M. E., Tokyo, vol. 21, no. 53, July 1918.

Tuckahoe

The Building of the "Tuckahoe," E. A. Suverkrop. Am. Mach., vol. 49, no. 7, Aug. 15, 1918, pp. 278-281, 10 figs. Record of the progress in building this 5500-ton collier in 27 days.

Turbo-Electric Propulsion

Electric Propulsion of Ships, Eskil Berg. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 477-479. Results obtained with electric drive on the "Jupiter"; installations for battleships and cruisers.

The Ljungström Turbo-Electric System of Ship Propulsion. Engineering, vol. 106, no. 2741, July 12, 1918, pp. 30-31, 16 figs. Description of the radial-flow steam turbines built for S. S. Wulsty Castle.

Welded Ships

An Electrically Welded Barge. Engineering, vol. 106, no. 2745, Aug. 9, 1918, pp. 142, 2 figs. Description of experimental rivetless ship constructed in Great Britain.

Britain's First Rivetless Ship. Nautical Gaz., vol. 94, no. 7, Aug. 17, 1918, p. 79. Discussion of possibilities and claimed disadvantages of the electric welding process.

Electrically-Welded Barge. Engineer, vol. 126, no. 3267, Aug. 9, 1918, pp. 122-123, 2 figs. Description of 275-ton rivetless barge constructed in Great Britain.

Electrically-Welded Ships. Elecn., vol. 81, no. 2099, Aug. 9, 1918, pp. 319-320, 1 fig. Description of experimental 275-ton rivetless barge constructed in Great Britain.

See also Building and Construction (Shipyard); Hoisting and Conveying (Overhead Carriers); Internal-Combustion Engineering (Diesel Engines.)

MATHEMATICS

Closed Curves

On Closed Curves Described by a Spherical Pendulum, Arnold Emch. Proc. Nat. Acad. of Science, vol. 4, no. 8, Aug. 1918, pp. 218-221. Results of analytical investigation of properties of these curves.

Hypergeometric Functions

The Practical Importance of the Confluent Hypergeometric Function, H. A. Webb and J. R. Airey. Lond., Edinburgh & Dublin, Phil. Mag., vol. 36, no. 211, July 1918, pp. 129-144, 10 figs. Tables and graph designs, differential equations solvable by means of these, and properties of the functions used in constructing the tables.

Single-Side Surface

A Surface Having Only a Single Side, C. Hering. Jl. Franklin Inst., vol. 186, no. 2, Aug. 1918, pp. 233-241, 13 figs. Equation and analytical investigation of the properties of a surface generated by a line moving along a circle, always remaining in planes passing through the axis of the circle and simultaneously revolving around the circle as its axis at half the angular rate of its movement along the circle.

Theory of Numbers

Arithmetical Theory of Certain Hurwitzian Continued Fractions, D. N. Lehmer. Proc. Nat. Acad. of Sci., vol. 4, no. 8, Aug. 1918, pp. 214-218. Arithmetical study of series of numbers which satisfy certain difference equations.

On the Representation of a Number as the Sum of Any Number of Squares, and in Particular of Five or Seven, G. H. Hardy. Proc. Nat. Academy of Sciences, vol. 4, no. 7, July 15, 1918, pp. 189-193. Research to deduce formulae for $s = 5$ and $s = 7$ from the theory of elliptic functions.

See also Electrical Engineering (Harmonics.)

MECHANICS

Beams

Distribution of Internal Work in Beams and Slabs, Henry T. Eddy. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 460-462, 1 fig. Difference in amounts of energy stored in steel indicates dissimilarity in structural functions of concrete.

Long Span Concrete Beams Should Have Fixed Ends, W. S. Tait. Eng. News-Rec., vol. 81, no. 8, Aug. 22, 1918, pp. 359-361, 5 figs. Method given by which computation of rigid frame may be readily made.

Maximum Positions of Moving Loads on Beams, F. K. E. Mech. World, vol. 64, no. 1646, July 19, 1918, p. 31, 1 fig. Information for finding the maximum bending moments and shears on beams due to the action of loads moving over them. From a paper read before the Inst. of Local Government Engrs. of Australasia.

Columns and Struts

Discussion on Final Report of the Special Committee on Steel Columns and Struts, W. H. Burr and R. von Fabrice. Proc. Am. Soc. Civ. Engrs., vol. 44, no. 6, Aug. 1918, pp. 875-895, 4 figs. Comparison of committee's results with present practice. (Concluded.)

Disks, Rotating

The Strength of Rotating Disks, H. Haerle. Engineering, vol. 106, no. 2745, Aug. 9, 1918, pp. 131-134, 8 figs. A mathematical treatment applied to steam turbines.

Dynamics

The Fundamentals of Dynamics, W. S. Franklin and B. MacNutt. Science, vol. 48, no. 1231, Aug. 2, 1918, pp. 113-116. Criticism of Prof. E. V. Huntington's discussions of elementary mechanics in Mar. 3, 1916, issue.

Earth Pressures

Computing Lateral Pressure of Saturated Earth, A. G. Husted. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 441-442, 2 figs. Proposed method takes account of separation of hydrostatic from earth pressure, but allows full hydrostatic pressure.

Gyroscopic Phenomena

On Stability Phenomena in a Ship Gyroscope and Single Rail Railroads (Om Stabilitetsfaenomeneme ved Skibsgyroskopet og Enskinnebanen), A. Bendixsen. Ingenioren, vol. 27, no. 56, July 13, 1918, pp. 399-406, 5 figs.

Indeterminate Structures

Equivalent Uniform Loads for Indeterminate Structures, D. B. Steinman. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, pp. 231-232, 3 figs. Method worked out for ordinary trusses applied to curve influence lines; wheel-load complications avoided.

Truss Members

Effect of Initial Stress on Redundant Truss Members, H. T. Booth. Aviation, vol. 5, no. 2, Aug. 15, 1918, pp. 91-93, 3 figs. Equations for the calculation of load stresses in diagonal tension braces when an initial tension is present; example of the action when diagonals are similar; illustration of the stress calculation for redundant members, with initial tension in two of them.

See also Bridges (Stresses); Pipe (Curved Pipe.)

METAL ORES

Manganese

Manganese, M. A. Allen and G. M. Butler. Univ. of Ariz. Bul. no. 91, Min. Tech. Series, no. 19, Aug. 1918, 32 pp. Composition of manganese minerals—Psilomelane, pyrolusite, manganite, wad, braunite, rhodochrosite, rhodonite and alabandite; tests

of manganese; occurrence and origin of ores; Arizona deposits; uses; manufacture of alloys.

Radium

Radium Ore Deposits, Richard B. Moore. Eng. & Min. Jl., vol. 106, no. 9, Aug. 31, 1918, pp. 392-393. From paper before Colorado meeting of Am. Inst. of Min. Engrs., Sept. 1918.

Rare Metals

Rare Earths and Rare Minerals. Eng. & Cement World, vol. 13, no. 3, Aug. 1, 1918, p. 78. Chief ores and uses of zirconium; method of refining graphite; preparation of ground mica.

Sulphur

Sulphur and Pyrites in 1917, Philip S. Smith. Am. Fertilizer, vol. 49, no. 4, Aug. 17, 1918, pp. 36-42 and 56-82. Production, imports, exports and character of domestic deposits of sulphur; qualities, uses, production and deposits of pyrites in the United States.

War Ores

War Materials of Colorado, A. H. Hubbell. Eng. & Min. Jl., vol. 106, no. 9, Aug. 31, 1918, pp. 382-384. Lead, zinc, gold, silver, tungsten and copper ores. Uranium, vanadium and radium produced from carnotite, vanadinite and pitchblende ores.

METAL-WORKING MACHINES

Drilling Spindles

A Vertical Slide and Drilling Spindle for the 2 in. Precision Lathe, C. H. C. Copeland. Model Engr., vol. 39, no. 898, July 11, 1918, pp. 19-21, 2 figs. Details of design.

Planers

Some New Ideas in Planer Practice. Woodworker, vol. 37, no. 6, Aug. 1918, pp. 26-27, 3 figs. Suggests advisability of shifting more of the feeding gear below the cutterhead so that it may pull the stock instead of pushing it, also slightly beveling the infeed edge of the bedplate under the cutterhead of single surfacers.

Portable Machines

Taking Machines to the Work, Edward K. Hammond. Machy., vol. 24, no. 12, Aug. 1918, pp. 1073-1081, 23 figs. Methods of applying portable machines in performance of shop operations, and advantages thus secured.

Presses

Ferracute Presses. Am. Mach., vol. 49, no. 10, Sept. 5, 1918, p. 450, 1 fig. Description with dimensions and other data of a single-action power press recently redesigned by the Ferracute Machine Co., Bridgeton, N. J., adapted for cutting and forming sheet-metal work of large area, such as coal hods, metal shingles, etc.

Railway Shop

Machine Tools and Appliances in Railway Workshops. Ry. Gaz., vol. 29, no. 5, Aug. 2, 1918, pp. 134-138, 8 figs. Illustrates and describes improvements in designs and types effected during the last 50 years.

Shell-Drilling Machine

Special Shell-Drilling Machines, Donald A. Baker. Machy., vol. 24, no. 12, Aug. 1918, pp. 1131-1132, 4 figs.

Tool Slide

A Tool Slide for the Drummond 4 in. or Similar Lathe, W. Baker. Model Engr. & Electn., vol. 39, no. 899, July 18, 1918, pp. 29-31, 3 figs. Details of design.

Wheel-Forcing Machine

A New Wheel Forcing Machine. Ry. Gaz., vol. 29, no. 4, July 26, 1918, p. 105. Product of Hollings & Guest, Birmingham, for removing heavy Foden and similar car wheels.

Wooden Dies

Using a Punch Press in Lieu of Bending Rolls, J. V. Hunter. Am. Mach., vol. 49, no. 6, Aug. 8, 1918, pp. 243-245, 6 figs. Wooden dies and a punch press used to accomplish some awkward bending jobs.

See also Engineering Materials (Stellite.)

METALLURGY

Alloys

Some Miscellaneous Alloys Made by the Metal and Thermit Cooperation. Reactions, vol. 11, no. 2, Second Quarter 1918, pp. 29-30. Uses of phosphor copper, phosphor tin, manganese titanium, manganese boron, silicon copper, chromium copper, cobalt copper, nickel copper, vanadium copper, titanium copper and manganese aluminum.

Brass Rolling

Chemistry of the Brass Rolling Mill, or the Relation of the Chemical Laboratory to the Brass Rolling Mill, M. B. Karr. Iron & Steel Inst. of Canada, vol. 1, no. 7, Aug. 1918, pp. 297-299. Significance of chemical control. Paper before Montreal Metallurgical Assn.

Rolling of Brass (Laminado del laton), J. Borrell Maciá. Revista Minera, year 69, no. 2645, June 24, 1918, pp. 309-313, 7 figs. Microstructure; composition of alloy for cold-rolling.

Non-Ferrous Alloys

Metallography Applied to Non-Ferrous Metals, Ernest J. Davis. Foundry, vol. 66, no. 313, Sept. 1918, pp. 427-429, 5 figs. Elementary article dealing with the science embracing a study of the internal structure of metals and alloys.

The Constitution and Influence of a Cored Dendritic Structure in Alloys, O. Smalley. Jl. Soc. Chem. Industry, vol. 37, no. 13, July 15, 1918, pp. 191T-200T and discussion 200T-201T, 22 figs. Genesis of microstructure; relation of composition and structure to physical properties; influence of varying casting temperature on properties of phosphor-bronze castings poured from the same melt; effect of heat treatment on properties of Admiralty gun metal; influence of impurities on properties of 70:30 brass before and after removal of the cast structure; relation of impurities to ghosts.

Stibnite Smelting

Blast-Furnace Smelting of Stibnite. Eng. & Min. Jl., vol. 106, no. 5, Aug. 3, 1918, pp. 211-210, 1 fig. Details of experimentation, showing effects of varying flux charge; minimum economic limit of coke required.

See also Electrical Engineering (Electrodeposition.)

MILITARY ENGINEERING

Anti-Aircraft Firing

The Problem of Anti-Aircraft Firing, X. Reille. Jl. Wash. Academy of Sci., vol. 8, no. 14, Aug. 19, 1918, pp. 465-480, 8 figs. Technical study of the general problems which anti-aircraft warfare has presented to the minds of artillerymen.

Artillery

Developments in Artillery During the War, J. Headlam. Sci. Am. Supp., vol. 85, no. 2215, June 15, 1918, pp. 370-371. How the changes in tactics affect technical matters and how the demands of the soldier may upset the plans of the scientist. (To be continued.)

Ballistics

Internal Ballistics, A. G. Hadcock. Proc. Royal Soc., vol. 94, no. A 663, July 1, 1918, pp. 179-509, 6 figs. Explanation and illustration of method for obtaining pressure-volume relation of gases in the bore of a gun from the instant of ignition of charge to the instant when shot leaves the gun, and mathematical expressions to plot the indicator diagram of charge when its nature and weight are known.

See also Building and Construction (Warehouse); Motor-Car Engineering (Ambulances); Roads and Pavements (Military Roads); Varia (Explosives.)

MINES AND MINING

Cementation

Cementation Process Applied to Mining, A. H. Krynauw. Colliery Guardian, vol. 116, no. 3005, Aug. 2, 1918, pp. 227-229, 9 figs. From paper before Chemical, Metallurgical & Min. Soc. of South Africa, May 1918.

Drilling

A Gasoline-Driven Diamond Drill Outfit, J. M. Longyear, Jr. Eng. & Min. Jl., vol. 106, no. 8, Aug. 24, 1918, pp. 343-345. Nearly 7,000 ft. of holes put down at a total cost of $2.152 per ft.; easily portable apparatus.

Fires

Mine Fire at Utah-Apex Mine, V. S. Rood and J. A. Norden. Safety Eng., vol. 35, no. 6, June 1918, pp. 356-364, 3 figs. Geology, mining methods and conditions of workings; conditions during and after the fire; results of analyses of air at different openings. Proc., A. I. M. E., Utah Section.

Some Results of Analysis of Airs from a Mine Fire, A. C. Blakeley and H. H. Reist. Jl. Indus. & Eng. Chem., vol. 10, no. 7, July 1, 1918, pp. 552-553. Data from samples taken at an anthracite coal mine generating a large quantity of methane.

Shafts

Shafts for Water Hoisting and Ventilation. Coal Age, vol. 14, no. 9, Aug. 29, 1918, pp. 397-400, 8 figs. "Water seal" permits shaft to be used for both ventilation and water hoisting. Description of first installation in United States.

Steel Guides in Shafts, J. Whitehouse. Jl. of South African Inst. of Engrs., vol. 16, no. 11, June 1918, pp. 200-204, 5 figs. Results obtained by the use of slotted steel guides in the turf shaft of the Village Deep Mine; suggested system for replacing guides.

Sprayers

Sprayer for Stone-Dusting in Mines, A. Rushton. Trans. Inst. Min. Engrs., vol. 55, part 3, July 1918, pp. 219-220, and discussion pp. 220-221. T-shaped wrought-iron-tubing apparatus operated by compressed air.

Washing

Recuperation of Combustible from Slag and Wash Residium (Récupération du combustible utilisable dans les scories et résidus de lavage). L'Echo des Mines et de la Métallurgie, no. 2581, July 7, 1918. Treatment of slag from metallurgical furnaces; washing of schists from mining installations.

MOTOR-CAR ENGINEERING

Ambulances

U. S. A. Ambulance and Trailer. Automotive Industries, vol. 39, no. 4, July 25, 1918, pp. 152-155, pp. 148-149, 3 figs. Review of specifications for an ambulance body for the class A A or G. M. C. ¾-ton chassis. Details of the spare-parts trailer and field litter.

Headlights

Automobile Headlights and Glare-Reducing Devices, L. C. Potter. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 627-632, 13 figs. Discussion of underlying principles of causes of glares; devices to prevent glare.

Omnibus

Omnibus Selection by Tests. Tramway & Ry. World, vol. 44, no. 2, July 11, 1918, p. 39, 1 fig. Specifications of 19-30 passenger type supplied to San Francisco Council.

Piston Displacement

Piston Displacement Chart for Four-Cylinder Engines, Any Bore and Stroke. Motor Age, vol. 34, no. 9, Aug. 29, 1918, p. 38. Gives piston displacement in cubic inches with 0.04 cu. in. limit of error.

Tractors

An Improved Chain Track for Tractors. Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, p. 280, 2 figs. Chain of sheet-steel sections having guided rocking joints with dust excluder and enclosed track carrier, developed by Ralph Wishon, of San Francisco, Cal.

Steering Creeper and Two-Wheeled Tractors, A. C. Woodbury. Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, pp. 269-270, 2 figs. Outline of various plans for steering tractors by other methods than that involved in Ackermann steering axle.

The Latest Electric Tractor. Auto, vol. 33, no. 30, July 26, 1918, pp. 535-536, 2 figs. Three-wheeled couple-gear tractor designed to do the same work as a horse team at greater speeds.

The Peoria Kerosene Tractor. Automotive Industries, vol. 39, no. 9, Aug. 29, 1918, pp. 366-367, 4 figs. Assembled of parts produced in specialized plants. Engine, clutch and transmission bolted together. Drawbar hitch can be laterally adjusted from driver's seat.

Tractor Gear Ratio Chart. Automotive Industries, vol. 39, no. 9, Aug. 29, 1918, p. 372. Diagram of curves to find gear reduction to give a certain tractor speed with a given engine speed and drive-wheel diameter.

Tractor Speed in Plowing, Fred M. Loomis. Motor Age, vol. 34, no. 9, Aug. 29, 1918, pp. 5-8, 3 figs. Study of effect of speed and soil conditions on plow draft and tractor drawbar pull.

Trucks

English and American Motor Oil Tank Trucks, Frank C. Perkins. Gas Eng., vol. 20, no. 9, Sept. 1918, pp. 413-417, 11 figs. Data and descriptions of several types.

Wheels

Making Cast Steel Wheels for U. S. Army Trucks. Foundry, Vol. 66, no. 313, Sept. 1918, pp. 396-401, 11 figs. Description of processes at Dayton Steel Foundry Co.

Wood Wheels Preferred by the Majority. C. N. Bonbright. Auto. Topics, vol. 50, no. 11, July 20, 1918, pp. 1102-1103 and 1107. Discussion of merits of materials for automobile wheels.

See also Hoisting and Conveying (Trucks, Industrial.)

MUNITIONS

Ansaldo Munition Factory

Ausaldo Steel Plants Rush Munitions. Mario de Biasi. Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, 4 pp., following 358, 12 figs. Gio. Ansaldo & Co., employing over 100,000 men, manufacture guns, cannon, shells, aeroplanes, submarines, merchant and battleships.

Bullets

Resistance of Copper Crushers During Compression. H. W. R. Mason. Arms & Explosives, vol. 26, no. 310, July 1, 1918, pp. 90-92. Description of tests and tables of results.

Cunard Shell Factory

The Cunard National Shell Factory. Engineering, vol. 106, no. 2740, July 5, 1918, pp. 3-6, 26 figs. Illustrated description of the work, the machines and tools used and certain fixtures.

Field Guns

The 75-Mm. Field Gun, Model 1916, M.III. Special Correspondence. Am. Mach., vol. 49, no. 8, Aug. 22, 1918, pp. 323-328, 4 figs. Description of latest type of 75-mm. field gun built by U. S. Government.

Howitzers, 6-in., British

The British 6-in. Howitzer. I. William Chubb. Am. Mach., vol. 49, no. 6, Aug. 8, 1918, pp. 231-242, 24 figs. First of a series on gun-making and repairing in English privately owned shops. Part II. in Am. Mach., vol. 49, no. 10, Sept. 5, 1918, pp. 411-423, 6 figs. Machining and heat-treating of jacket; assembling howitzer; fitting of new A-tubes and repair of damaged howitzers.

Madsen Automatic Gun

The Madsen Automatic Gun. Sci. Am. Supp., vol. 86, no. 2224, Aug. 17, 1918, pp. 108-110, 6 figs. Details of weapon for which great efficiency is claimed. From the Engineer (London).

Marine Torpedoes

Early History of the Marine Torpedo. H. H. Manchester. Am. Mach., vol. 49, no. 10, Sept. 5, 1918, pp. 435-438, 11 figs. Historical sketch of prototype of modern torpedo, commencing with earliest known type, in 1285, and dealing with Bushnell's torpedo, 1810.

Naval Gun Cars

Gun Transport Car for the Navy. Ry. Mech. Eng., vol. 92, no. 8, Aug. 1918, pp. 457-459, 4 figs. Details of special car for transporting 16-in. guns.

Special Cars for Transporting Heavy Naval Guns. Ry. Age, vol. 65, no. 5, Aug. 2, 1918, pp. 212-214, 4 figs. Details and drawings.

Revolvers

Revolvers and Automatic Pistols (Les revolvers et les pistolets automatiques). L. Cabanes. Génie Civil, vol. 73, no. 4, July 27, 1918, pp. 64-67, 10 figs. Recent developments in manufacture of French type, Nagant Russian and Austro-Hungarian no. 1898. (To be continued.)

Shell, 18-lb., British

Special Machine-Tool Fixtures for Making the British 18-lb. Shell. Chester B. Hamilton, Jr. Am. Mach., vol. 49, no. 9, Aug. 29, 1918, pp. 395-396, 5 figs.

See also Metal-Working Machines (Shell Drilling Machine.)

PAINTS AND FINISHES

Ironwork

Corrosion of Ironwork. J. N. Friend. Surveyor, vol. 54, no. 1384, July 26, 1918, p. 43. Summary of results of author's researches on the usefulness of paint for protecting ironwork. Abstract of paper before Iron & Steel Inst. Also published in Can. Engr., vol. 35, no. 7, Aug. 15, 1918, p. 149.

Paint and Its Application to Railway Structures. Eng. Rev., vol. 32, no. 1, July 15, 1918, pp. 20-21. Preservative and decorative purposes in the industry. From report of Com. of Am. Ry. Bridge and Building Assn.

Standards for Protective Finishes for Iron. E. F. Later. Foundry, vol. 66, no. 313, Sept. 1918, pp. 424-426. Results of series of tests which indicate protective qualities of various metals and thickness of coatings.

(See also Mining Engineering (Corrosion.)

PHYSICS

Air

Physics of the Air. W. J. Humphreys. Jl. Franklin Inst., vol. 186, no. 2, Aug. 1918, pp. 211-232, 5 figs. Rocket, ball, sheet, beaded, return and dark lightning; length of streak; nature of the discharge; temperature; visibility; spectrum; thunder; rumbling; cerannograph; chemical effects, explosive effects. (Continuation of serial).

Electrolytes

Colloidal Electrolytes: Soap Solutions as a Type. J. W. McBain. Jl. Soc. Chem. Industry, vol. 37, no. 14, July 31, 1918, pp. 249 T-252 T. Results of experiments on the constitution, hydrolysis, conductivity, osmotic properties, and viscosity of soap solutions.

Electronic Frequency

Electronic Frequency and Atomic Number. Paul D. Foote. Phys. Rev., vol. 12, no. 2, Aug. 1918, pp. 115-121. Examination of Dr. Allen's formula for relation between atomic frequency and Moseley's atomic number, in the light of data on ionization potentials recently published by Franck, Davis, Bazzoni, Tate, Foote and Hughes.

Emulsions

Water-in-Oil Emulsions. A. U. Max Schlaepfer. Jl. Chem. Soc., vols. 113 and 114, no. 668, June 1918, pp. 522-526. Experiments performed with the aid of a finely divided solid, insoluble in both liquids, which is more easily wetted by the oil than by the water phase.

Flame Propagation in Gases

Flame Propagation in Gaseous Mixtures. G. A. Burrell and A. W. Gauger. Sci. & Art of Min., vol. 28, no. 26, July 27, 1918, p. 475. From technical paper 150 summarizing experiments of U. S. Bureau of Mines on limits of complete inflammability of mixtures of mine gases, etc.

Optics

On the Correction of Optical Surfaces. A. A. Michelson. Proc. Nat. Academy of Sciences, vol. 4, no. 7, July 15, 1918, pp. 211-212. Suggested modifications in Mr. Twyman's interferometer method.

Transmission of Light Through Water. S. L. E. Rose. Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 577-578, 2 figs. Table of experimental values of transmission factor T in the equation $I = I_0 \times T^f$ where I_0 is the initial intensity and I the intensity after passing through f feet of water.

Polarization

Polarization in Case of Moving Electrodes. Carl Barus. Science, vol. 48, no. 1236, Sept. 6, 1918, pp. 253-254. Experiments at Brown University in which a strong residual polarization in direction of charging current was obtained; elucidation of phenomenon.

Reciprocity

Law of Reciprocity (Loi de réciprocité). J. B. Pomey. Revue Générale de l'Electricité, vol. 4, no. 5, Aug. 3, 1918, pp. 131-132. Equation derived from the principle of virtual velocities, between the electromotive force e_k in each of the branches of a network and the function of the derivative of the energy with respect to the current α_k; also reciprocal equation for the current in terms of the derivatives with respect to the electromotive forces.

Relativity

General Relativity Without the Equivalence Hypothesis. L. Silberstein. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 211, July 1918, pp. 94-128. Chief aspects and illustrations of the physical implications of the principle of relativity as proposed by Einstein, but without placing gravitation in connection with the fundamental tensor which appears in the line-element of the world.

Spectra

Extreme Ultra-Violet Spectra of Hot Sparks in High Vacua. R. A. Millikan and R. A. Sawyer. Phys. Rev., vol. 12, no. 2, Aug. 1918, pp. 167-170, 1 fig. Report of experiments. Abstract of paper before New York meeting Am. Phys. Soc.

Structural Matter

On the Dynamics of the Electron. M. Nad Saha. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 211, July 1918, pp. 76-87. Theory aiming at the formulation of the dynamics of the electron without following the preconceived ideas of classical mechanics. Reasoning is based on Lorentz's theorem of ponderomotive force and the principle of relativity.

Some Properties of Metals Under the Influence of Alpha Rays. A. G. McGougan. Phys. Rev., vol. 12, no. 2, Aug. 1918, pp. 122-129, 4 figs. Yale University experimental research involving: An attempt to present a fresh clean surface of metal to incident x-rays by scraping the surface of the metal while in a high vacuum; similar experiment for a surface of mercury by method of overflow, thereby stretching the surface film and producing a new clean surface of mercury.

Surface Friction

Surface Friction of Fluids. E. Parry. New Zealand Jl. of Sci. & Technology, vol. 1, no. 3, May 1918, pp. 154-156. Proposes as general law of fluid friction: For geometrically similar surfaces, $R/\rho v^2$ is a function of lv/u, where R is the resistance per unit of area, ρ the density of fluid, v the relative velocity, l a dimension of the surface, and u the kinematic viscosity; deductions from experimental data in regard to flow of water in pipes.

Vibrations

On Ship Waves, and on Waves in Deep Water Due to the Motion of Submerged Bodies. G. Green. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 211, July 1918, pp. 48-63. Extension of Lord Kelvin's method for determining wave motion to any arbitrary conditions of applied surface pressure; discussion of the wave disturbance due to a cylinder and a sphere moving with constant velocity at a considerable depth beneath the surface.

Variably Coupled Vibrations—Both Masses and Periods Unequal. E. H. Barton and H. M. Browning. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 211, July 1918, pp. 36-57. Theory of general case for double-cord pendulum and experimental results. (Continued from Oct. 1917 and Jan. 1918 issues.)

Vibration: Mechanical, Musical and Electrical. Nature, vol. 101, no. 2545, Aug. 8, 1918, pp. 456-459, 5 figs. Brass instruments and the low "F"; monochord vibrations; violin vibrations. (Concluded.)

See also Steel and Iron (Electric Resistance of Steel; Magnetic Properties of Steel.)

PIPE

Costs

Cost of Laying Iron Pipe. Mun. Jl., vol. 45, no. 6, Aug. 10, 1918, pp. 111-112. Unit figures for estimating cost under various conditions as to size, depth of trench and costs of material and labor.

Clay Pipe, Vitrified

The Use of Vitrified Clay Pipe for Irrigation Lines. V. E. Piollet. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 73-75. Requirements of construction.

Curved Pipe

Stresses in Curved Pipes. J. S. Henzell. Mech. World, vol. 64, no. 1646, July 19, 1918, pp. 28-29, 1 fig. Analytical study of the stresses in pipes which suffer external restraint. (Continuation of serial; preceding article published July 5.)

Joints

Methods of Making Sewer Pipe Joints. Contract Rec., vol. 32, no. 36, Sept. 4, 1918, pp. 718-719. Specifications for several joints. From discussion before Boston Soc. Civ. Engrs.

New Concrete Pipe Joint Designed for High Pressure. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, p. 216, 1 fig. Joint proves watertight under tests for heads up to 250 ft.; can be used for diameters as small as 4 in.

Pressure Pipe

Recent Developments in Reinforced Concrete Pressure Pipe for Water Supply Lines. W. R. Harris. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 58-59, 3 figs. Present

maximum working pressure, structural features, types of expansion joints.

The Choice of Material for Pressure Pipes, Ralph Bennett. Jl. of Electricity, vol. 41, no. 3, Aug. 1, 1918, pp. 123-124. Study of available types (steel, concrete, wood stave).

Welded Pipe

The Manufacture of Welded Pipe, S. A. Hand. Am. Mach., vol. 49, no. 7, Aug. 15, 1918, pp. 285-288, 7 figs. Description of methods used by National Tube Co.

POWER GENERATION AND SELECTION

Aqueduct Construction

Construction of Famous Aqueduct Facilitated by Electricity, C. W. Geiger. Elec. Rev., vol. 73, no. 7, Aug. 17, 1918, pp. 241-242, 5 figs. Description of use of electricity in building the Los Angeles Aqueduct.

Auxiliaries, Drives for

Motor Driven Auxiliaries (I), C. Grant. Mech. World, vol. 63, no. 1641, June 14, 1918, p. 283. Comparison between turbine and electric-motor drives. (To be continued.)

Costs

Economic Proportion of Hydroelectric and Steam Power, Frank G. Baum, Proc. Am. Inst. Elec. Engrs., vol. 37, no. 9, Sept. 1918, pp. 1115-1119, 2 figs. Method for obtaining a curve showing "Total cost per kilowatt-year for hydroelectric and steam power" for any percentage combination of generation.

Electric Power Generation

A Review of Recent Electrical Engineering Progress, E. W. Rice, Jr. Elec. News, vol. 27, no. 16, Aug. 15, 1918, pp. 25-28. Efficiency in converting water to electric power; improvements in steam-producing devices; possibility of further advances in steam-turbo-electric unit; elements in the efficiency problem; linking of plants for exchange of power; electric furnace; electrification and transportation. Presidential address, A. I. E. E. convention.

Mills, Continuous

Operation of Motor-Driven Continuous Mills, H. C. Cronk. Blast Furnace & Steel Plant, vol. 6, no. 8, Aug. 1918, pp. 336-338. Operating data giving power consumption per ton, including auxiliary motors. Paper before Cleveland Section, Assn. Iron & Steel Elec. Engrs.

Mining

Electrical Manufacturers May Look to Metal Mining for Greater Output, W. A. Scott. Elec. Rev., vol. 73, no. 4, July 27, 1918, pp. 119-120, 3 figs. Present demand for metals creates increased mining activity; steadily widening field for electrical equipment and electric power in the metal mines.

Electricity in Coal Mining Operations, Frank Huskinson. Elec. Rev., vol. 73, nos. 7 and 8, Aug. 17 and 24, 1918, pp. 245-247, 8 figs., and 287-289, 6 figs. Mine haulage by electric locomotives; electric rotary drills, electric blasting; advantages of electric service.

How Electrical Methods Are Speeding Up Coal Mining Operations (III), T. R. Hay. Elec. Rec., vol. 24, no. 3, Sept. 1918, pp. 28-29, 8 figs. Details of manner in which electrical equipment is used inside and about the mine: electric mine hoists; pumping equipment; ventilating system; miscellaneous uses of electrical energy.

The Consideration of Items of Practical Importance in Connection with Mining Electrical Engineering, Chris. Jones. Proc. South Wales Inst. of Engrs., vol. 34, no. 2, July 19, 1918, pp. 159-206, 24 figs. Considerations, curves and data regarding the efficiency and cost of generating, distributing and applying electrical power in mines and kindred industries: periodicity of supply; power factor; earthed and insulated neutral; reactance; cables; transformers; earthing.

Tire Manufacture

Electricity in the Manufacture of Automobile Tires, R. B. Jackson. Elec. Rev., vol. 73, no. 4, July 27, 1918, pp. 121-124, 5 figs. Process of tire making; choices of motors and salient features of control, applying especially to plant of International India Rubber Co., South Bend, Ind.

Woodworking Machinery

Motor Drive for Woodworking Machinery, C. E. Clewell. Elec. World, vol. 72, no. 6, Aug. 10, 1918, pp. 253-256, 4 figs. Induction motors used extensively for timber sawing and planing; power requirements of typical machines; examples of successful motor applications.

POWER PLANTS

Rand Plant

Turbine House Plant Operation, wth Special Reference to the Rand Power Companies' Plants, T. G. Otley and V. Pickles. Trans. South African Inst. Elec. Engrs., vol. 9, part 5, May 1918, pp. 68-88, 11 figs. Discussion of some points in connection with efficient operation of turbine plant and its attendant auxiliaries.

Shaft Drive

More Power from Shaft by Use of Turbine. Elec. News, vol. 27, no. 15, Aug. 1, 1918, p. 33. General features of shaft drive, consisting of a low-pressure turbine and a Danbee reduction gear, recently installed in a Western Pennsylvania paper mill.

Small Power Plant

How to Manage Small Power Plants, W. T. Wardale. Model Engr. & Elecn., vol. 39, nos. 899 and 900, July 18 and 25, 1918, pp. 34-35, 2 figs, and pp. 47-48, 6 figs. Requirements of pump water gland packing; manner of packing. (Continuation of serial.)

Winona Plant

The New 5000-Kilowatt Station at Winona, Minn. Elec. Rev., vol. 73, no. 9, Aug. 31, 1918, pp. 321-324, 4 figs. Mechanical and electrical features of Wisconsin Railway, Light and Power Co.'s plant.

PRODUCER GAS AND GAS PRODUCERS

Suggestions for Gas Producer Operation, F. Denk. Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 386-388, 5 figs. Tests and curves showing relations of factors influencing operation; depth and position of ash bed determined by unique device; careful attention essential in successful operation.

PUMPS

Air Lift

Performance of New Air-Lift Pumping Plant at Galesburg, Ill., J. Oliphant. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 57-58. Conditions of operation and results of tests.

Deep-Well Pump

Importance of Diameter of Deep Wells. Mun. Jl., vol. 45, no. 6, Aug. 10, 1918, pp. 105-107. Where deep-well pumps are used, diameter of well limits size of pump; lower part may be of smaller diameter.

Lift Pumps

Lift and Force Pumps, John H. Perry. Domestic Eng., vol. 84, no. 7, Aug. 17, 1918, pp. 239-241, 5 figs. Construction and operation of pumps with steady flow and high efficiency.

Mine Pump

Handling Mine Water, Henry E. Cole. Coal Age, vol. 14, no. 6, Aug. 8, 1918, pp. 264-266, 2 figs. Work pump must perform; character of water; types of pumps.

Turbine Pump

Pumping Equipment at Thorold, Ont., W. L. Adams. Can. Engr., vol. 35, no. 6, Aug. 8, 1918, pp. 121-122. New installation consisting of a two-stage 1500-gal. turbine pump directly connected to a 250-hp. induction motor, with control and auxiliary apparatus.

RAILROAD ENGINEERING, ELECTRIC

Circuit Breakers

High-Speed Circuit Breakers for Chicago, Milwaukee & St. Paul Electrification, C. H. Hill. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 623-626, 5 figs. Gives details of construction.

Electrification

Electrification of New York Connecting Railway. Ry. Gaz., vol. 29, no. 3, July 19, 1918, pp. 81-84. Method of operation; trolley supporting structures; catenary trolley system; communication lines; transmission lines.

Norfolk and Western Electrification Helping Directly to Win the War. Elec. Ry. Jl., vol. 52, no. 8, Aug. 24, 1918, pp. 322-325, 5 figs. Fifty per cent. increase in mountain-grade capacity through electrification.

Tendencies in Electrification, E. A. Palmer. Ry. Rev., vol. 63, no. 5, Aug. 3, 1918, pp. 176-178. Brief résumé of the leading steam railway electrification projects in the United States. From a paper before Pacific Coast Railway Club, June 1918.

The Electrification of the Chicago, Milwaukee & St. Paul Railway, A. E. du Pasquier. Trans. S. A. Inst. E. E., June 1918, pp. 94-126, 18 figs. Criticism of J. W. Kirkland's paper published in July and Aug. 1917 journals under same title; other railway electrification data in connection with Kirkland's inferences.

The Electrification of the Chicago, Milwaukee & St. Paul Ry., R. Beeuwkes. Elec. Ry & Tramway Jl., vol. 39, no. 932, Aug. 9, 1918, pp. 42-46, 5 figs. Regeneration on down grades; engineering and construction; results of operation; comparison of train delays and of steam and electric locomotive performance. (Continued from July 12 issue.)

Heating of Cars

Why Not Use Wasted Energy to Help Heat Cars? Elec. Ry. Jl., vol. 52, no. 7, Aug. 17, 1918, pp. 291-292, 2 figs. Possibilities of utilizing heat from car motors and resistance grids discussed and results of some tests given.

Line Construction

Applying Common-Sense in Line Construction, Charles R. Harte. Elec. Ry. Jl., vol. 52, no. 7, Aug. 17, 1918, pp. 278-282, 14 figs. Money and time can be saved by close cooperation of designer and constructor, and by attention to details commonly overlooked.

Locomotive Control

A New Type of Mine Locomotive Control, L. W. Webb. Gen. Elec. Rev., vol. 21, no. 9, Sept. 1918, pp. 620-622, 8 figs. A controller developed for use on large mine locomotives where the capacity of hand-operated drum controls would be exceeded. Wiring connections of two-, three- and four-motor controllers.

Metering Power

Study of Car Energy Saving at Dubuque, L. E. Gould. Elec. Ry. Jl., vol. 52, no. 8, Aug. 24, 1918, pp. 334-336, 4 figs. Tests made on level and hill lines show that savings as high as 26 per cent. can be obtained by the use of meters as checking devices.

Operation

High Passenger Density the Outstanding Feature of New Service to Hog Island. Elec. Ry. Jl., vol. 52, no. 10, Sept. 7, 1918, pp. 404-408, 8 figs. Details and data of Philadelphia Rapid Transit Co.'s cars, including new features of door control.

Increased Economy Results from Correct Operation of Car Equipment, C. W. Squier. Elec. Ry. Jl., vol. 52, no. 7, Aug. 17, 1918, pp. 275-277, 4 figs. Effects of various rates of acceleration and braking on the schedule speeds and power consumed; relation of number of stops and their length to cost of operation.

Selling Transportation on a Commercial Basis, Clarence Renshaw. Elec. Ry. Jl., vol. 52, no. 10, Sept. 7, 1918, pp. 415-416. Sale methods of other lines of business apply to electric railways; some requisites for good service.

Section Cars

Gasoline Motor Section Cars Decrease Labor and Cost of Track Maintenance, Clifford A. Elliott. Elec. Ry. Jl., vol. 52, no. 10, Sept. 7, 1918, p. 423, 3 figs. Maintenance-of-way department, Pacific Electric Rys., uses such cars and motor velocipedes in maintaining signals and tracks.

Single-Phase Locomotives

New Single-Phase Locomotives for the Swiss Bundesbahn, Hugo Studer. Elec. Ry. Jl., vol. 52, no. 10, Sept. 7, 1918, pp. 411-413, 8 figs. Description of four sample locomotives ordered for the Swiss Bundesbahn and several types developed by the Oerlikon Co. in connection with this electrification.

Track-Circuit Design

A Graphical Method of Solving D. C. Track-Circuit Problems, H. M. Proud. Ry. Engr., vol. 39, no. 463, Aug. 1918, pp. 157-159, 5 figs. Use of graphs showing total track conductance against volts on rails in finding volts on relay and train shunt. (Continuation of serial.)

Track Work

Special Track Work for Street Railways, J. V. Hunter. Am. Mach., vol. 49, no. 8, Aug. 22, 1918, pp. 335-338, 8 figs. Engineering work in connection with switches, frogs and crossovers.

RAILROAD ENGINEERING, STEAM

Bolsters, Truck

Design of Cast Steel Truck Bolsters. L. E. Endsley. Ry. Rev., vol. 63, no. 5, Aug. 3, 1918, pp. 152-154, 3 figs. States results in a bolster mast with no holes in side walls and subsequent results after holes were cut.

Brakes

A Mechanical Brake Control System for Railways. Engineer, vol. 126, no. 3264, July 19, 1918, pp. 58-59, 7 figs. Description of details of "Reliostop" railway brake control system.

Air Brake Association in Fuel Saving. Railroad Herald, vol. 22, no. 9, Aug. 1918, pp. 195-196. Recommendations tending to decrease leakage of brake pipes on freight trains in order to save 6,000,000 tons of coal annually. Report of committee.

Road Tests of the A. S. A. Brake. Ry. Mech. Eng., vol. 92, no. 8, Aug. 1918, pp. 453-456, 4 figs. 100-car train run on Virginian with A. S. A. and Westinghouse brakes.

Tests of the Automatic Straight Air Brake on the Virginian Railway. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, pp. 244-247, 6 figs. Résumé of equipment, data and chronograph records of five positions of brake valve and of speed and stop distances.

Cars

Cars for Special and Excursion Traffic, Victorian Railways. Ry Engr., vol. 39, no. 463, Aug. 1918, pp. 160-161, 3 figs. Arrangement details of a pattern car, weighing 26 tons, with capacity for 82 passengers, recently completed at the Government railway shops at Newport, England.

High Capacity Cars on a Narrow Gauge Railway in India. Frederick C. Coleman. Ry. Age, vol. 65, no. 6, Aug. 9, 1918, pp. 265-266, 3 figs. Description of freight cars of the Sheffield & Twinberrow type for the Kalka-Simla Ry.

Crossings

Concrete Slab Railroad Crossings. Eng. & Cement World, vol. 13, no. 3, Aug. 1, 1918, p. 34. How they were placed at Cedar Rapids, Ia.

Freight House

Pennsylvania Completes Freight House at Chicago. Ry. Age, vol. 65, no. 5, Aug. 2, 1918, pp. 215-219, 8 figs. Description of new structure of two-level type.

Hot Boxes

The Hot Box Problem. N. Marple. Railroad Herald, vol. 22, no. 9, Aug. 1918, pp. 196-198. Causes originating the hot box and suggestion to prevent them by making car owner responsible. Paper before Niagara Frontier Car Men's Assn.

Hump Yard

15,000-Car Hump Yard Near Chicago Planned by Illinois Central Railroad. Eng. News-Rec., vol. 81, no. 7, Aug. 15, 1918, pp. 313-316, 1 fig. Terminal for main-line trains, from which transfer trains will serve local yards, will have power-operated switches, motor-car service for car riders and L. C. L. transfer facilities for 450 cars daily.

Locomotive Boilers

Design and Maintenance of Locomotive Boilers. Boiler Maker, vol. 18, no. 8, Aug. 1918, pp. 231-232. Application of autogenous welding to construction and renewal of smokeboxes, flues, staybolts, fireboxes and mud rings. Report of Committee on Design and Maintenance of Locomotive Boilers, before joint meeting of Master Car Builders and Master Mechanics Assns. Also published in Ry. Jl., vol. 24, no. 8, Aug. 1918, pp. 21-23.

Reducing Maintenance Costs on Locomotive Boilers. W. R. Toppan. Railroad Herald, vol. 22, no. 9, Aug. 1918, p. iv-A. How a terminal system cut down its flue and staybolt work following installation of a water-softening plant.

The Arrangement of Tubes in Locomotive Boilers. H. C. Webster. Mech. World, vol. 64, no. 1646, July 19, 1918, p. 33, 4 figs. Study of the arrangement necessary to secure maximum efficiency.

Locomotive Engines

Modern Locomotive Engine Design and Construction. Ry. Engr., vol. 39, no. 463, Aug. 1918, pp. 151-156, 8 figs. Locomotive feedwater heating systems, superheated steam and methods of superheating. (Continuation of serial.)

Locomotive Exhaust Nozzles

Locomotive Exhaust Nozzles. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, pp. 251-253, 2 figs. Study of part played by form of aperture in results obtained, based on physical character of phenomenon.

Locomotives

A Three-Cylinder Locomotive. Engineer, vol. 126, no. 3265, July 26, 1918, pp. 70-72, 10 figs. Illustrations and drawings, and special reference to the Gresley valve gear. Locomotive in operation on the Great Northern Ry., England.

New 3-cylinder Locomotive, Great Northern Railway. C. S. Lake. Model Engr., vol. 39, no. 897, July 4, 1918, pp. 1-5, 6 figs. Features of locomotive recently built at the Doncaster Works, England.

Compound Mallet for the N. & W. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, p. 263, 1 fig. Dimensions of 2-8-8-2 type.

N. & W. 267-ton Mallet Locomotive. H. W. Reynolds. Ry. Mech. Eng., vol. 92, no. 8, Aug. 1918, pp. 445-450, 10 figs. Data, drawings and description of locomotive and its tender.

New Pacific and Mikado Type Locomotives for the Chicago, Burlington and Quincy Railroad. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, pp. 248-249, 2 figs. Dimensions of 4-6-2 and 2-8-2 types.

New 2-8-0 Type Locomotives for the Victorian Railways. Ry. Gaz., vol. 29, no. 2, July 12, 1918, pp. 51-52, 4 figs. Diagrams and dimensions.

First U. S. Standard Locomotive. Ry. Mech. Eng., vol. 92, no. 8, Aug. 1918, pp. 436-438, 5 figs. Description with drawings of the light Mikado type built by the Baldwin Locomotive Works.

The First of the U. S. Railroad Administration Locomotives. Railroad Herald, vol. 22, no. 9, Aug. 1918, pp. 194-195. General features of Mikado (2-8-2) type recently completed by the Baldwin Locomotive Works.

Baldwin Locomotive Works Completes the First of the U. S. Standard Locomotives. Mikado type, 2-8-2. Assigned to the Baltimore and Ohio. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, pp. 239-240, 1 fig. Description and dimensions.

Small Locomotives of Special Types. Engineer, vol. 126, no. 3267, Aug. 9, 1918, pp. 111-112, 2 figs. Descriptions with dimensions and data of gasoline-driven locomotives of 20 and 40 hp., used at present for trench railways, but applicable for industrial railways of various types.

The Influence of Type on Locomotive Performance. Ry. Gaz., vol. 29, no. 4, July 26, 1918, pp. 108-112, 6 figs. Criticism of design for an engine of the 4-4-0 type proposed in April 12 issue, and table of comparative particulars of express locomotives of this type.

Mexican Railways

Serious Condition of the Railways in Mexico. Ry. Age, vol. 65, no. 7, Aug. 16, 1918, pp. 307-309. Report by Latin-American Division of Bureau of Foreign and Domestic Commerce.

Rail Failures

Derailment from Rail Failures Due to Transverse Fissures. Railroad Herald, vol. 22, no. 9, Aug. 1918, pp. 190-192, 4 figs. Diagrams, micro-photos, and results of physical and chemical analyses of fractured rails. Report of Chief of Bureau of Safety, I. C. C., covering investigation of an accident which occurred on the Central of Ga.

Rail Renewing

Labor Saving Appliances in Rail Renewing on the C., B. & Q. R. R. Ry. Rev., vol. 63, no. 7, Aug. 17, 1918, pp. 229-233, 4 figs. Rail-laying machine, rail-drilling machine, tie sawing machine.

Repair Shop

A Western Railroad Repair Shop. Frank A. Stanley. Am. Mach., vol. 49, no. 6, Aug. 8, 1918, pp. 249-252, 15 figs. Describing some methods and tools used.

Locomotive Repair Developments in Great Britain. Railroad Herald, vol. 22, no. 9, Aug. 1918, pp. 183-184. Construction details of Great Eastern Railway recently built. Special shops capable of carrying out repairs on between 40 to 50 engines simultaneously.

Running Repairs of Locomotive Boilers and Approved Methods of Wash-Out of Boilers. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, pp. 241-243, 6 figs. Data of mileage between washouts made by passenger and freight locomotives; cost of washing; methods and tools used.

Signaling

Electro-Pneumatic Interlocking Plants. H. A. Wallace. Ry. Signal Engr., vol. 11, no. 8, Aug. 1918, pp. 250-253. Details and operation of switches and signals; air valve; electro-pneumatic machine; "SS" system of signal control. Abstract of paper before Tex. Regional Committee of Ry. Signal Assn.

New Mechanical Plant on Chicago and Alton. Ry. Signal Engr., vol. 11, no. 8, Aug. 1918, pp. 239-243, 3 figs. Interlocker on a double-track main line crossing single-track road, designed not to require night leverman.

Track

Interesting Reconstruction Work on the Erie. Ry. Age, vol. 65, no. 6, Aug. 9, 1918, pp. 248-252, 9 figs. Work on a 35-mile section of double-track line in Indiana including some heavy grade revision.

Labor-Saving Devices for Track Maintenance. Ry. Rev., vol. 63, no. 5, Aug. 3, 1918, pp. 172-176. From a paper by E. Stimson before New England Railroad Club, May 1918.

Trans-Australian Railway

The Trans-Australian Railway. Engineer, vol. 126, no. 3264, July 19, 1918, pp. 56-57, 1 map. Difficulties of construction; description of the route; progress of construction; special problems encountered; the country traversed.

Turntables

Construction, Care and Maintenance of Turntables. Ry. & Loco. Eng., vol. 31, no. 8, Aug. 1918, pp. 250-251, 2 figs. Features of improved types.

See also *Cement and Concrete* **(Ties)**; *Factory Management (Railway Stores)*; *Labor (Railroad Employees)*; *Munitions (Naval Gun Cars.)*

REFRACTORIES

Testing and Inspection of Refractory Brick. C. E. Nesbitt and M. L. Bell. Blast Furnace & Steel Plant, vol. 6, no. 8, Aug. 1918, pp. 341-344, 8 figs. Results of tests on spalling (resistance to sudden thermal change), crushing and slag penetration; conclusion drawn from differences in the figures obtained. Paper before Am. Soc. Testing Materials.

See also Testing and Measurements (Refractories, Testing).

REFRIGERATION

Ammonia-Absorption Machines

Gas Formation in Ammonia Absorption Refrigerating Machines, Its Causes and Remedy. E. C. McKelvy and A. Isaacs. Am. Soc. Refrig. Engrs. Jl., vol. 4, no 5, March 1918, pp. 447-463, 1 fig. Report of experimental work undertaken by special committee to investigate nature and sources of gases by means of an experimental bomb consisting of a piece of 4-in. steel pipe closed at both ends by clamped blind flanges with a female recess. Read before Am. Soc. Refrig. Engrs.

Ammonia Conservation

Conservation of Ammonia and Coal. E. N. Fiedmann and Van R. H. Greene. Ice & Refrig., vol. 54, no. 5, May 1918, pp. 268-269. Stuffing box and decomposition losses; temperature of cooling water and condenser pressure; saving coal; undesirable coal mixtures; increased evaporation. Paper before Long Island Ice Manufacturers' Assn.

Ammonia Leakage

Cost of Ammonia Leakage. Reactions, vol. 11, no. 2. Second Quarter 1918, pp. 31-36. Possibility of considerable loss of ammonia through apparently inconsiderable leaks.

Brine-Cooling System

The Practical Side of the Low Temperature Compression System. H. Solan. Am. Soc Refrig. Engrs. Jl., vol. 4, no. 6, May 1918, pp. 549-556, 4 figs. Description of three installations operated with brine-cooling systems.

CO_2 Machines

Carbonic Acid Refrigerating Machines. J. C. Goosmann. Ice & Refrig., vol. 54, no. 5, May 1918, pp. 272-274, 3 figs. Some conditions that have delayed general adoption of carbon-dioxide refrigerating machines; practical equality of three refrigerants; actual equality of horsepower required.

Cold Accumulators

Cold Accumulators and Their Application to the Refrigerating Industry. Am. Soc. Refrig. Engrs. Jl., vol. 4, no. 6, May 1918, pp. 541-548, 2 figs. Types of tanks and formulæ for calculations. Read before Milwaukee Section of A.S.R.E.

Hospital Refrigerating Plant

Service for the Sick. Power Plant Eng., vol. 22, no. 15, Aug. 1, 1918, pp. 605-610, 6 figs. Description of power plant at Blodgett

Memorial Ho[illegible] Grand Rapids, Mich.; [illegible]

Ice Making

Modern Station [illegible] Raw Water Ice Plant. [illegible] vol. 55, no. 3, Sept. 1, 1918, [illegible] 13 figs. Details of plant and complete equipment of plant; arrangement of engines, freezing and ice storage rooms; method of operation and details of [illegible] electrical equipment and cost of power.

Preventing Red Cores. Leon Block. Ice & Refrig., vol. 54, no. 5, May 1918, pp. 270-271, 1 fig. Results of a discussion at a meeting of Refrig. Engrs.

Refrigeration and Ice Making. Charles L. Hubbard. Indus. Management, vol. 56, no. 2, Aug. 1918, pp. 105-109, 11 figs. Examples of apparatus and machinery used in military camps and on shipboard.

Treatment of Water for Raw Water Ice Making. M. F. Newman. Am. Soc. Refrig. Engrs. Jl., vol. 4, no. 6, May 1918, pp. 527-540. Account of different processes. Presented before the A.S.R.E.

Ice Structure

The Crystal Structure of Ice. A. St. John. Proc. of the Nat. Academy of Sciences, vol. 4, no. 7, July 15, 1918, pp. 193-197. Photographic spectrum investigation by means of a Coolidge tube with tungsten target excited by an induction coil with mercury turbine interrupter.

Insulating Materials

Report Upon Tests of Heat Insulating Materials for Cold Storage Rooms, W. M. Thornton. Cold Storage, vol. 21, no. 244, July 18, 1918, pp. 177-178. Method of testing; relative efficiency from total ice melted; quantity of heat transmitted.

Liquefaction of Gases

Argon, Lighting and Industries Employing Very Low Temperatures (L'argon, l'éclairage et l'industrie des basses températures), Georges Claude. Mémoires et Compte Rendu des Travaux de la Société des Ingénieurs Civils de France, year 71, nos. 1-3, Jan.-Mar. 1918, pp. 66-72, 2 figs. Process of liquefaction of gases and description of apparatus for obtaining a liquid mixture of 75 to 80 per cent argon and the rest oxygen; argon and nitrogen in electric lamps.

Loss in Ammonia Manufacture

Sources of Loss During the Manufacture of Concentrated Ammonia Liquor, A. Marsden. Jl. Soc. Chem. Industry, vol. 37, no. 14, July 31, 1918, pp. 230T-232T. Suggestions to remedy sources of losses when making ammonia.

Salt Solutions

The Freezing Points of Concentrated Solutions and the Free Energy of Solution of Salts, W. H. Rodebush. Jl. Am. Chem. Soc., vol. 40, no. 8, Aug. 1918, pp. 1204-1213. Experimental determination of freezing-point concentration curves for the commoner salt solutions; thermodynamic equations for the free energy of solution and examples of their application.

See also Drying (Low Temperature.)

RESEARCH

Factory Chemical Laboratory

Relation of the Chemical Laboratory to the Factory, M. B. Karr. Can. Mfr., vol. 38, no. 9, Sept. 1918, pp. 21-23, 3 figs. Before Montreal Metallurgical Assn.

Factory Research Laboratory

Planning a Research Laboratory for an Industry, C. E. K. Mees. Jl. Soc. Chem. Industry, pp. 201T-202T. Two possible forms of organization "departmental" system and "cell" system. Abstract of paper before New York Section of Soc. Chem. Industry.

National Physical Laboratory

The National Physical Laboratory in 1917-18. Engineering, vol. 106, no. 2743, July 26, 1918, pp. 91-96. From the annual report, dealing with work of the various departments.

See also Testing and Measurements (Railroad Testing Laboratory.)

ROADS AND PAVEMENTS

Asphalt Roads

[illegible] Asphalt Pavements. Chas. A. Mullen. Better Roads & Streets, vol. 8, no. 6, June 1918, pp. 225-229 and 252-253, 5 [illegible]s. Paper before Fifth Can. Good Roads Congress.

[illegible] Construction and Maintenance [illegible] Rock Asphalt Roads, [illegible] Mun. & County Eng., vol. 55, [illegible] pp. 49-50. Characteristics [illegible] of these roads; recom[illegible]

Concrete Roads

[illegible] Pavements at New [illegible] Samuel H. Lea. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. [illegible] townsite roadways of [illegible] throughout at Larg[illegible] special templet used for [illegible]

Concrete Road Construction During [illegible] Temperatures. Eng. & Contracting, vol. 50, no. 6, Aug. 7, 1918, pp. 147-148. Sand, water and subgrade heated before mixing and laying concrete; concrete protected by a covering of canvas and hay.

Concrete Roads in New Zealand. Surveyor, vol. 54, no. 1383, July 19, 1918, p. 30. Method of construction in Auckland City.

How to Get the Best Surface on a Concrete Road, A. H. Hunter. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 47-49. Remarks on the construction of forms, operation of templets, building of joints, finishing surfaces and use of the roller and belt.

Cost Keeping

Cost Keeping System for County Highway Work. Contract Rec., vol. 32, no. 34, Aug. 21, 1918, pp. 657-659. Elements applying to all cases. From paper before Wash. Assn. of County Engrs. Also published in Eng. & Contracting, vol. 50, no. 6, Aug. 7, 1918, pp. 145-147.

Earth Roads

Method of Building Earth Roads in Kane County, Illinois. George N. Lamb. Eng. & Contracting, vol. 50, no. 6, Aug. 7, 1918, pp. 140-141, 1 figs. Laying out curves; standard cross sections for grading; the operations; cost of earth road grading.

The Necessity of Engineering Supervision in Construction and Maintenance of Earth Roads. H. Ross Mackensie. Eng. & Contracting, vol. 50, no. 6, Aug. 7, 1918, pp. 155-157. From paper before Regina Branch of Can. Soc. of Civ. Engrs.

Easement Curves

Easing and Super-Elevating the Highway Curve. Contract Rec., vol. 32, no. 32, Aug. 7, 1918, pp. 617-618. Table and diagram of super-elevations and offsets for easement curves, used by the highway engineers of King County, Wash., in construction of paved roads.

Frost Action

Impervious Bituminous Wall Suggested to Prevent Seepage Under Paving. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, pp. 226-228, 3 figs. Extensive study made of vertical movements of pavements with reference to frost action; distribution of moisture in clay and loam sub-grades and effect of walling off shown by charts.

Gravel Roads

Iowa Methods of Constructing Gravel Roads. Eng. & Contracting, vol. 50, no. 10, Sept. 4, 1918, pp. 247-248. From bulletin issued by Iowa Highway Commission.

Highways

Highway Carries Twelve Times as Much Local Freight as Railroad. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, pp. 224-226. Shipments by Baltimore road increase 480 per cent in year, saving railroads 39,923 ton miles.

Notes on Highway Design, J. L. Harrison. Eng. & Contracting, vol. 50, no. 10, Sept. 4, 1918, pp. 237-238. Preliminary investigation; population benefited; volume of traffic; grades; distance; curvature.

Macadam Pavements

Method and Cost of Reducing Excessive Crown on a Macadam Pavement. E. Earl Glass. Eng. & Contracting, vol. 50, no. 6, Aug. 7, 1918, pp. 144-145, 2 figs. Filling in sides of the road to reduce crown described.

Military Roads

Roads in [illegible] Section of American Forces. Repair, Widening and Resurfacing. Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 8, Aug. 22, 1918, pp. 348-352, 8 figs. Heavy traffic by motor trucks and artillery on practice marches necessitates continuous maintenance.

Road Construction

Asphalt Resurfacing in Los Angeles, C. W. Geiger. Mun. Jl., vol. 45, no. 7, Aug. 17, 1918, pp. 123-125, 6 figs. Mixture for wearing surfaces and binder furnished by municipal asphalt plant. Surface heating method employed. All done by day labor.

Handling Materials on a Michigan Road Job. Municipal Jl., vol. 45, no. 10, Sept. 7, 1918, pp. 181-182, 6 figs. Gravel for concrete dredged from neighboring lake, transported, measured and mixed.

The "National" Pavement in New Haven. Mun. Jl., vol. 45, no. 8, Aug. 24, 1918, pp. 143-145. Methods used in resurfacing old macadam and brick pavements with a cover composed of about 18 per cent asphalt and 82 per cent pulverized earthy matter, 50 per cent of which passes through a 200-mesh sieve, and nothing being retained on a 10-mesh screen.

Road-Construction Machinery

The Use of Modern Machinery in County Road Construction, C. B. Scott. Good Roads, vol. 16, no. 9, Aug. 31, 1918, pp. 80 and 83. Various modern machines and devices; and new ways in which they are being used. Paper before North Carolina Good Roads Assn.

Sand-Clay Roads

Maintaining Sand-Clay Roads in North Carolina. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, p. 49. Account of investigation regarding failure of roads.

Tar Surfaces

English and American Practice in the Construction of Tar Surfaces and Pavements, A. H. Blanchard. Better Roads & Streets, vol. 8, no. 6, June 1918, pp. 230-234 and 253, 11 figs. Paper before Fifth Can. Good Roads Congress. Also published in Eng. & Contracting, vol. 50, no. 6, Aug. 7, 1918, pp. 142-144.

War Conditions

Policy of U. S. Highways Council Regarding Highway and Street Work During the War. Eng. & Contracting, vol. 50, no. 10, Sept. 4, 1918, pp. 232. Text of regulations, effective Sept. 10, 1918.

Road Building in Michigan Under War Conditions, Frank F. Rogers. Good Roads, vol. 16, no. 10, Sept. 7, 1918, pp. 89-90 and 92. Paper before Mich. State Good Roads Assn.

Water, Action of

The Action of Water on the Road Subgrade and Its Relation to Road Drainage, J. L. Harrison. Mun. & County Eng., vol. 55 no. 2, Aug. 1918, pp. 50-52. Limitations of tile drainage; capillary attraction; heavy-clay soils; freezing of dry subgrades; cracking; use of Telford base; carrying capacity of subgrade.

See also Engineering Materials (Paving Blocks.)

SAFETY ENGINEERING

Acetylene

Report of the Department Committee on Cylinders for Dissolved Acetylene. Acetylene & Welding Jl., vol. 16, no. 177, June 1918, pp. 98-99. Results of experiments carried out at the Home Office Experimental Station, Eskmeals, Cumberland, with the object of ascertaining the result of igniting the acetylene in a pocket space formed in the porous material inside a cylinder, and the danger, if any, of such ignition. (Continuation of serial.)

Brick Making

Safety in Brick Making. Am. Industries (Accident Prevention Supp.), vol. 19, no. 1, Aug. 1918, 4 pp., 7 figs. Sketches of machines enclosed in standard guards.

Fires

Some Lessons from a Disastrous Carhouse Fire. Elec. Ry. Jl., vol. 52, no. 6, Aug. 10, 1918, pp. 239-241, 3 figs. Results of a fire caused by explosion of oil tank of a 44,000-volt lightning arrester.

Mine Rescue Stations

The Equipment and Organization of Mine Rescue Stations, A. J. Moorshead. Safety Eng., vol. 36, no. 1, July 1918, pp. 23-27. Prevention of accidents; necessary equipment and its care; first-aid supplies; exploring teams.

Scaffolding Construction

Safety in Scaffolding Construction. Building News, vol. 115, no. 3315, July 17, 1918, pp. 34-35. Reproduction of rules and regulations promulgated by the Department of Labor and Industry of the Pennsylvania Industrial Board.

Wood Alcohol

Wood Alcohol in War Time, Winifred Hathaway. Survey, vol. 40, no. 22, Aug. 31,

1918, pp. 609-611. Discusses unsuspected danger faced by thousands of workers in munition plants and elsewhere.

See also Hoisting and Conveying (Wire Ropes.)

SANITARY ENGINEERING

Air Checking of Sewer Pipe

Reducing Air Checking in Cooling Sewer Pipe. B. T. Sweely. Brick & Clay Rec., vol. 53, no. 4, Aug. 13, 1918, pp. 291-292. Procedure claimed to have reduced air checking 60 per cent. in middle-west plant.

Alum in Filters

The Selection of Alum for Filter Plants. Fire & Water Eng., vol. 64, no. 7, Aug. 14, 1918, p. 116. Extract of suggestions in annual report of Ontario Provincial Board of Health.

Sewage Disposal

Auto-Eductor Solves Sewage Tank Difficulty. Mun. Jl., vol. 45, no. 8, Aug. 24, 1918, pp. 145-146. Removal of large amount of greasy scum and sludge from septic tank that had resisted other pumping appliances.

Comparative Value of Activated Sludge and Sprinkling Filters, T. Chalkley Hatton. Contract Rec., vol. 32, no. 33, Aug. 14, 1918, pp. 638-641. Variation in standard effluent; area required for plants; loss of head and effect of temperature; clarification; odors; flies; disposal of sludge; cost of plants.

Design and Construction of the New Sewage Treatment Plant at Sedalia, Mo., R. E. McDonnell. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 71-73. Intercepting and grit chamber; Imhoff settling tanks; sludge-drying beds; sprinkling filters.

Design and Construction of Water and Sewerage Works at the Hog Island Shipyard. W. H. Blood. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 54-57. Difficulties met; purification plant; distribution system; hydrants; sewage pumping and treatment.

Design Details of Proposed Works for the Collection and Disposal of Sewage at Pottstown, Pa., C. E. Collins. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 61-64. Pumping station; settling tanks; dosing tank; filter; sludge-drying beds; capacity, operation and care.

Miles Acid Process May Require Aeration of Effluent. F. W. Mohlman. Eng. News-Rec., vol. 81, no. 5, Aug. 1, 1918, pp. 235-236, 1 fig. Experiments show that sulphur dioxide in effluent deoxygenates several volumes of diluting water.

Novel Sewerage System and Sewage Plant at Mt. Horeb, Wis., W. G. Kirchoffer. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, p. 61. Description of system made entirely of concrete.

Sewage Disposal. Edward Wilcox. Surveyor, vol. 54, no. 1386, Aug. 9, 1918, pp. 66-67. Presidential address, Assn. of Mgrs. of Sewage Disposal Works. (Concluded.)

Sewering an Army Cantonment. Mun. Jl., vol. 45, no. 8, Aug. 24, 1918, pp. 141-142. Construction work at Camp Bowie, Tex., done by the Gen. Construction Co., at a cost of $80,000.

Sprinkling Filter System and Auxiliaries Versus the Activated Sludge Process. T. Chalkley. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 67-70. Comparison as to standard effluent, area, loss of head, temperature, clarification, odors and cost.

The Deoxygenating Effect of the Effluent from the Miles Acid Process of Sewage Treatment. F. W. Mohlman. Eng. & Contracting, vol. 50, no. 7, Aug. 14, 1918, pp. 166-167, 1 fig. Concludes that the Miles acid effluent contains unoxidized sulphur dioxide which is oxidized at the expense of the dissolved oxygen in the water in which the effluent is diluted and that it may be oxidized before dilution by aeration for a short time with relatively small quantities of air.

Water-Purification Plants

Design and Construction of the New Water Purification Plant and Pumping Station at Checotah, Okla., V. V. Long. Mun. & County Eng., vol. 55, no. 2, Aug. 1918, pp. 70-71.

Mechanical Rapid Sand Filtration Plant for Dorval, P. Q. Contract Rec., vol. 32, no. 32, Aug. 7, 1918, pp. 615-617, 1 fig. Details of construction.

STANDARDS AND STANDARDIZATION

Inductance

Standard of Mutual Induction (Etalon d'induction mutuelle). M. A. Guillet. Jl. de Physique, vol. 7, Mar. Apr. 1917, pp. 75-87, 1 fig. Formula determining standard; theory and operation of apparatus. Presented before French Phys. Soc. (Continuation of serial.)

Screw Standards

Gaging Screws. H. J. Bingham Powell. Am. Mach., vol. 48, no. 25, June 20, 1918, pp. 1045-1046. Attempt to show way to correlate the numerous existing standards and to secure their interchangeability.

See also Aeronautics (International Aircraft Standards); Paints and Finishes; Railroad Engineering, Steam (Locomotives); Testing and Measurements (Gages.)

STEAM ENGINEERING

Boiler Code

Table of Allowances. F. R. Burlingame. Boiler Maker, vol. 18, no. 8, Aug. 1918, pp. 218-219, 1 fig. Figured from formulæ given in the revision of the A.S.M.E. Boiler Code published in January.

Corrosion

Surface Defects of Condenser Tubes Causing Corrosion. W. R. Webster. Page's Eng. Weekly, vol. 33, no. 724, July 26, 1918, p. 42. Abstract of paper before Am. Soc. for Testing Materials.

What Is the Cure for Condenser Tube Corrosion? Hartley LeH. Smith. Elec. Ry. Jl., vol. 52, no. 7, Aug. 17, 1918, pp. 283-285. Writer believes longer life will be secured from condenser tubes by proper selection of materials and care in manufacture, rather than by modification of conditions directly under control of operator.

Water Softening to Correct Boiler Corrosion. William Henry Hobbs. Ry. Rev., vol. 63, no. 5, Aug. 3, 1918, pp. 167-170. Prevention of incrustation, pitting and corrosion; reference to experiments to determine the relative corrosibility of various salts and manner in which these tendencies can be corrected.

Engine Economy

Improving Engine Economy. M. A. Saller. Power Plant Eng., vol. 22, no. 15, Aug. 1, 1918, pp. 617-620, 6 figs. Increasing capacity and efficiency of steam engines by proper valve setting, eliminating leakage and maintaining speed regulation.

Exhaust Steam

Utilization of Exhaust Steam for Generating Electrical Energy in Collieries. (Considérations sur l'utilisation des vapeurs d'échappement dans les houillères en vue de la production d'énergie électrique). A. Barjon. L'Industrie Electrique. Year 27, no. 627, Aug. 10, 1918, pp. 287-293, 7 figs. Utilization of exhaust steam; turbo-generator groups; types of turbines. (Continuation of serial.)

Lubrication, Engine Cylinder

Problems of Steam Cylinder Lubrication. W. F. Osborne. Blast Furnace & Steel Plant, vol. 6, nos. 8 and 9, Aug. and Sept. 1918, pp. 338-341 and p. 389. Importance and difficulties of lubrication; features influencing method of lubricating, such as the cylinder, the valves, steam flow and steam exhaustion.

Pipe Lines

Relation Between Loss of Pressure and Pipe Size in Long Steam Lines. H. Eisert. Jl. Engrs. Club of Baltimore, vol. 7, no. 6, Dec. 1918, pp. 103-122, 2 figs. Technical study based on Weisbach's formula for determining flow resistance of a fluid through a conduit of uniform cross-section.

Pumping Engines

Historical Data of Steam Pumping Engines. A. O. Doane. Fire & Water Eng., vol. 44, no. 9, Aug. 28, 1918, pp. 148-149. Comparison of various types in capacity and cost.

Two Newcomen Atmospheric Pumping Engines. Cerald T. Newbould. Colliery Guardian, vol. 116, no. 3005, Aug. 2, 1918, pp. 230-231, 3 figs. One built in 1787 and the other in 1823 are still in operation. From paper before Midland Inst. of Min., Civ. and Mech. Engrs. Also published in Iron & Coal Trades Rev., vol. 97, no. 2631, Aug. 2, 1918, pp. 118-119, 8 figs.

Steam Plants, Statistics on

Notes on the Development of the Use of Steam Since 1876. Robert M. Anderson. Stevens Indicator, vol 35, no. 2, April 1918, pp. 97-107. Corliss engines, steam turbines, electric-power systems; statistics giving increase of various prime movers and electric motors during ten-year periods.

Turbine Theory

A New Theory of the Steam Turbine. Harold Medway Martin. Engineering, vol. 106, no. 2740, July 5, 1918, pp. 1-3, 1 chart. First of a series of articles; contains a steam chart based on Callender's tables and formulæ.

Turbines

Modern Steam Turbines. J. Humphrey. Iron & Coal Trades Rev., vol. 97, no. 2632, Aug. 9, 1918, pp. 147-148, 1 fig. A review of recent types.

New Turbine Plant at Hull. Tramway & Ry. World, vol. 44, no. 2, July 11, 1918, pp. 11-14, 8 figs. Installation of three-phase turbo-generating plant on scheme to augment existing high- and low-tension direct current system.

Volcanic Steam Generation

Power from Volcanic Steam. Jl. Royal Soc. of Arts, vol. 66, no. 3429, Aug. 9, 1918, p. 602. Brief notes on Southwestern Tuscany plant where electric energy is obtained from low-pressure alternating turbines operated with volcanic steam.

See also Air Machinery (Turbo Compressors); Engineering Materials (Boiler Plates); Marine Engineering (Turbo Electric Propulsion); Railroad Engineering, Steam (Locomotive Boilers, Locomotive Engines, Locomotive-Exhaust Nozzles); Testing and Measurements (Steam, Quality of.)

STEEL AND IRON

Blast-Furnace Operation

Blast-Furnace Bears. J. E. Stead. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 9, 42 pp., 5 figs. Discussion of variable character of bear (mass of metal found below the hearth level of a blast furnace after it has been blown out); evidence of the existence of kish, sulphides of manganese and iron, cyano-nitrite of iron, titanium dioxy nide, oxides, silicates, phosphides and carbide crystals, and unique specimens, in the composition of some bears; hypotheses explaining their genesis.

Conserving Manganese in Steel Production. A. N. Diehl. Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 366-367. Discussion read before Am. Iron & Steel Inst.

Copper Tuyeres for Blast-Furnaces. A. K. Reese. Proc. British Iron & Steel Inst., May 3-2, 1918, Paper no. 6, 6 pp., 3 figs. Details of design and adaptation.

Fuel Economy in Blast-Furnaces. T. C. Hutchison. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 5, 14 pp., 6 figs. Report of work done at the Skinningrove Iron Co.'s plant, consisting of two 8-ft. hearths and three 10 ft. hearth furnaces, and inferred observations on the importance of effectually cleaning the ironstone at the belt, the conditions that secure long life of furnace lining, and fuel economy. Also published in Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 118, pp. 378-380, 3 figs.

Inquiry on Blast-Furnace Practice in the United Kingdom. Proc. British Iron & Steel Inst., May 2-3, Paper no. 2, 19 pp. Effect of the mechanical and chemical conditions of raw materials on furnace working; influence of dimensions of the bell relative to stock line; use of double bells; size and quality of firebricks; use of waste gas for calcining ironstone. Report of committee summarizing answers received from owners of blast furnaces.

Principal Changes in Blast Furnace Lines. J. G. West. Blast Furnace & Steel Plant, vol. 6, no. 8, Aug. 1918, pp. 323-329, 29 figs. Bronze cooling plates inserted in brickwork; development of wider hearths; use of high blast temperatures; discussion of theoretical lines. From paper before Am. Iron & Steel Inst. (Concluded.)

Briquetting Iron Ores

Present Knowledge and Practice in Briquetting Iron Ores. Guy Barrett and T. B. Rogerson. Automotive Eng., vol. 3, no. 7, Aug. 1918, pp. 310-311, 1 fig. Methods followed and machines used in this work, with special reference to conditions in United States, England and Continental Europe. (Third of series.)

The Briquetting of Pulverable Iron Ore and Blast-Furnace Slime. (Le briquetage des minerais de fer pulvérulents et des poussiers de hauts fourneaux). G. Barrett and T. B. Rogerson. Génie Civil, vol. 73, no. 4, July 27, 1918, pp. 70-73. Collection of practical data. From a report before Iron and Steel Inst. (To be continued.)

Cast Iron

The Fluidity of Molten Cast Iron. Matthew Riddell. Foundry, vol. 66, no. 313, Sept. 1918, pp. 408-411, 1 fig. From a paper before British Foundrymen's Assn.

Chemical Constitution of Steel

Iron, Carbon aand Phosphorus. J. E. Stead. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 19, 24 pp., 23 figs. Account of experiments performed in order to investigate the effect of introducing carbon, by cementation, into homogeneous solid solutions of iron and phosphorus and temperature ranges in which free phosphide of iron passes in and out of solid solution in iron.

Non-Metallic Inclusions: Their Constitution and Occurrence in Steel. A. McCance. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper No. 14, 48 pp., 36 figs. Effect in strength of stressed material; position in relation to the ingot; etching reagents; influence of aluminum on sulphides; oxidation products of manganese sulphide; acid open-hearth slags and their reduction products; equilibrium conditions in liquid steel; results of analyses and examination of microphotographs of etchings.

Note on Inclusions in Steel and Ferrite Lines. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 13, 6 pp., 13 figs. Results of experiments which led the author to the conclusion that the phosphorus associated with non-metallic inclusions in steel leads to the formation of ferrite ghost lines.

Coke

The Importance of Coke Hardness. G. D. Cochrane. Proc. British Steel & Iron Inst., May 2-3, 1918, Paper no. 3, 11 pp., 3 figs. Results of experiments which led the author to establish as an axiom that the practical success of the working of a blast furnace is chiefly dependent on the mechanical condition of the coke used.

Cold-Working

The Effect of Cold Work on the Divorce of Pearlite. J. H. Whiteley. Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 17, 9 pp., 14 figs. Investigation in the study of Eggertz color test for combined carbon consisting of experiments in which drillings of pearlitic steels were annealed in vacuo for about an hour at 650 deg. cent.; a small section of a hammered bar was heated in vacuo for periods of 15 min. at successive temperatures between 459 and 690 deg. cent., and finally a section of the hammered bar and a piece of the unstrained steel were heated together for 4 hr. at 600 deg. cent.

The Effects of Cold-Working on the Elastic Properties of Steel. J. O. Van Den Broek. Proc. British Iron & Steel Inst., May 2-3, 1918. Paper no. 18, 41 pp., 15 figs. Materials and apparatus; manner of conducting tests; measurements; discussion of data; effects of cold-stretching and cold-twisting; electric resistivity of cold-worked steel; effects on alloy steels; theory; microstructure; tests on steel balls; analysis of commercial process. Published also in Engineering, vol. 106, no. 2743, July 26, 1918, pp. 99-105, 15 figs.

Damascene Steel

Damascene Steel. N. Belaiew. Proc. British Iron & Steel Inst., May 2-3, Paper no. 20, 22 pp., 5 figs. History, external characteristics and three principal processes of manufacture; Anossoff's classification of patterns of damascene blades; author's analyses; explanation for ductility, malleability and elasticity of damascene alloys.

Electric Furnace Melting

Electric Cast Iron and Steel Manufacture (La production électrothermique des fontes et aciers), Jean Escard. Revue Générale des Sciences, year 29, no. 12, June 30, 1918, pp. 366-373, 4 figs. Héroult furnace; experiments of Sault Sainte-Marie; California New-Héroult furnaces; Trollhattan electric furnace; Keller process.

Electric Furnace Production of Cast Iron and Steel (La production électrothermique des fontes et aciers), J. Escard. Revue Générale des Sciences, year 29, no 13, July 15, 1918, pp. 401-413, 18 figs. Comparative study of five methods of manufacturing steel.

Electric Steel Production for Small Units, A. V. Farr. Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 381-383, 6 figs. Description of cold-metal method predominating in electric-furnace units under 10 ton capacity; data on 6-ton Héroult furnace making high carbon chrome steel. Paper before Am. Drop Forge Assn.

Metallurgical Electric Furnaces. Engineering, vol. 106, no. 2743, July 26, 1918, pp. 86-87, 8 figs. Electric steel-refining furnaces; features of control. From discussion by Faraday Society at Manchester, Feb. 1918.

Electric Steel, Franklin D. Jones. Machy., vol. 24, no. 12, Aug. 1918, pp. 1104-1110, 11 figs. Advantages of electric furnace; types and methods of operation.

Electric Resistance of Steel

Concerning the Constitution of Martensite in Low Carbon Steel and Its Influence on the Electrical Resistance (Rorande martensitens Konstitution vid låg Kolhalt ach dess inflytande på elektriska ledningsmotståndet). C. Benedicks and E. Walldow. Bihang till Jern-Kontorets Annaler, vol. 19, no. 6, June 15, 1918.

Eutectic Alloys

Eutectic Alloys, Clifford W. Nash. Chem. Eng & Min. Rev., vol. 10, no. 114, March 1918, pp. 161-166, 9 figs. Study in the structure of iron-carbon eutectic and eutectoid. (Concluded.)

Ferro Alloys

Carbon-free Ferro Tungsten. A. F. Braid. Reactions, vol. 11, no. 2, Second Quarter 1918, pp. 28-29. Uses of ferrotungsten and tungsten powder.

The Manufacture of Ferro Alloys in Colorado. Robert M. Keeney. Eng. & Min. Jl., vol. 106, no. 9, Aug. 31, 1918, pp. 405-409. From paper before Colorado meeting of Am. Inst. of Min. Engrs., Sept. 1918.

Ingots

Defects in Steel Ingots, J. N. Kilby. Iron & Steel Inst. of Canada, vol. 1, no. 7, Aug. 1918, pp. 288-296, 13 figs. Previous conclusions upon influence of casting in relation to cracks in ingot or bar; composition of slags of different steel-making processes, their physical state, and relationship in ultimate product; basic open-hearth steel, with some reference to electric process. Abstract of papers before Sheffild Soc. of Engrs. and Staffordshire Iron & Steel Inst., coupled with further observations and results. Published also in Proc. British Iron & Steel Inst., May 2-3, 1918, Paper no. 12, 24 pp., 13 figs.

Magnetic Properties of Steel

Correlation of the Magnetic and Mechanical Properties of Steel, Chas. W. Burrows. Sci. Papers of the Bureau of Standards, no. 272, March 29, 1916, 208 pp., 42 figs. Relation of the magnetic to the other characteristics; magnetic behavior under influence of mechanical stresses greater and smaller than elastic limit; inhomogencities and flaws; bibliography.

Development of Magnetic Susceptibility in Manganese Steel by Prolonged Heat Treatment, Charles F. Brush. Proc. Am. Phil. Soc., vol. 57, no. 4, 1918, pp. 344-353, 3 figs. Experiments performed on 19 bars, each 6 in. long and ½ in. in diameter.

Rolling Mills

Plate Production Expedites Shipbuilding, A. M. Staehle. Blass Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 361-365, 8 figs. Rolling-mill capacities increased 20 per cent and material saved by efficient plate specifications; many new plate mills built; description of Liberty Mill of Carnegie Steel Co.

Practical Pointers on Wire Rod Rolls, W. S. Standiford. Blast Furnace & Steel Plant, vol. 6, no. 9, Sept. 1918, pp. 367-369, 3 figs. Consideration of design of passes and roll trains; draft influenced by form of pass, structure of metal and degree of heat.

Producing Special Steel to Suit Specific Purposes. Can. Machy., vol. 20, no. 2, July 11, 1918, pp. 33-34, 9 figs. New strip mill at Massillon, Ohio.

New Installation for Rolling Alloy Strips, Blast Furnace & Steel Plant, vol. 6, no. 8, Aug. 1918, pp. 319-321. Departure in strip-mill practice by the Nat. Pressed Steel Co., Massillon, O.

The Slick Wheel Mill. Iron Age, vol. 102, no. 9, Aug. 29, 1918, pp. 491-498, 17 figs. Commercial products formed directly from large rolled bars by rolling-forging process at Cambria Steel Works.

Scrap Steel

Discard Steel. Steel & Metal Digest, vol. 8, no. 8, Aug 1918, p. 474. Uses and properties of shell discard steel.

See also Chemical Technology (Analysis, Steel); Testing and Measurements (Steel Testing).

TESTING AND MEASUREMENTS

Balloon Fabrics

See Permeability, below.

Carbon Dioxide Recorder

CO_2 Recorders in the Boiler House, John B. C. Kershaw. Engineer, vol. 126, no. 3264, July 19, 1918, pp. 45-47, 10 figs. Boiler efficiencies and need for improvement; heat losses in the boiler plant and their control; seven types of automatic apparatus for recording CO_2 percentages described.

Clocks, Electric

Electrical Horology, H. R. Langman. Model Engr. & Elecn., vol. 39, no. 902, Aug. 8, pp. 72-77, 6 figs. Compilation of systems of electric clocks. (To be continued.)

Dynamometers

Commercial Dynamometers (IV), P. Field Foster. Mech. World, vol. 64, no. 1647, July 26, 1918, pp. 42-43, 4 figs. The rope-brake type invented by Lord Kelvin. (Continuation of serial.)

Elastic-Limit Recorder

An Improved Elastic Limit Recorder. Automotive Industries, vol. 39, no. 7, Aug. 15, 1918, p. 287, 1 fig. Attachment to a standard testing machine by means of which it is claimed one person can accurately determine the elastic limit of specimens both in tension and compression.

New Elastic Limit Recorder, J. L. Jones and C. H. Marshall. Iron Age, vol. 102, no. 7, Aug. 15, 1918, pp. 391-392, 2 figs. Sumner instrument enables tests to be made accurately and rapidly. From paper before Am. Soc. for Testing Materials, June 1918.

Electrical Measurements

A New Method of Measuring Alternating Currents and Electric Oscillations, I. Williams. Elecn., vol. 81, no. 12, July 19, 1918, pp. 253-255, 5 figs. Abstract of paper before Phys. Soc.

Fluid Gage

Coats Precision Fluid Gage. Am. Mach., vol. 49, no. 10, Sept. 5, 1918, p. 451, 1 fig. Data and description of a precision gage operating on the fluid principle, and used as a comparator, primarily, and not an actual measuring machine. Built by the Coats Machinery Co., Philadelphia, Pa.

Gages

Industrial Gages (Les calibres industriels), Ch-Ed. Guillaume. Revue Générale de l'Electricité, vol. 4, no. 5, Aug. 3, 1918, pp. 141-145, 1 fig. Evolution of length standards; joint action of International Bureau of Weights and Measures and Technical Section of the Artillery; temperature of definition; coefficients of expansion of several metals; standards; official resolutions.

Gloves, Rubber

Lineman's Rubber Gloves Under Test, F. C. Perkins. Wireless Age, vol. 5, no. 12, Sept. 1918, pp. 1038-1041, 2 figs. Method used by the Duquesne Light Co., Pittsburgh.

Hardness of Metals

A Law Governing the Resistance to Penetration of Metal When Tested by Impact with a 10 mm. Steel Ball; and a New Hardness Scale in Energy Units, C. A. Edwards. Jl. Inst. Mech. Engrs., no. 5, June 1918, pp. 335-369, 9 figs. Experimental investigation from which author establishes as the law governing penetration resistance of plastic metals $d = C\ E^{0.25}$, where d = diameter of indent made by 10-mm. ball, C is a constant varying with hardness of metal, and E = total energy of impact.

Testing Hardness of Metals by the Boyelle-Morin Apparatus, C. J. Bowen Cooke. Jl. Inst. Mech. Engrs., no. 5, June 1918, pp. 331-333, 4 figs. Outfit and method of making a test.

Lubricants, Testing

Methods of Conducting Tests of Lubricants on Internal Combustion Engines, S. F. Lentz. Lubrication, vol. 5, no. 9, July 1918, pp. 4-9. Suggestions regarding extent to which local conditions should be considered in estimating importance of results obtained in tests.

The Testing of Lubricants, Raymond Francis Yates. Am. Mach., vol. 49, no. 7, Aug. 15, 1918, pp. 289-291, 3 figs. Explains various characteristics of lubricating oils and greases and how they may be tested with simple apparatus.

Meters, Electric

Demand Meters, J. A. Laubenstein. Gen. Elec. Rev., vol. 21, no. 8, Aug. 1918, pp. 573-576, 6 figs. Consideration of the actual measurement of "demand" and description of various types of meters designed for the purpose of determining the maximum demand rate of charge for power.

Effect of Daily Variations of Frequency on Reading of Induction Meters (Influence des variations journalièrs de la fréquence sur les indications des compteurs d'induction), M. A. Durand. Revue Générale de l'Electricité, vol. 4, no. 5, Aug. 3, 1918, pp. 136-140, 6 figs. Result of tests performed by Central Electrical Laboratory. From paper before French Society of Electricians.

Report of the Meter Committee. Elec. News, vol. 27, no. 13, July 1, 1918, pp. 45-48, 4 figs. Study of four methods for determining efficiently the power factor; account of recent changes in standard instruments Paper before Can. Elec. Assn.

Meters, Heat

Heat Meters (Les compteurs calorimétriques ou compteur de chaleur), R. Joëssel. Génie Civil, vol. 73, nos. 1 and 2, July 6 and 13, 1918, pp. 12-13 and 28-30, 3 figs. Résumé of work done to devise an instrument for measuring the amount of heat supplied to a fluid; applications and utility of this instrument. (Concluded.)

Moving Photomicrographs

How Moving Photomicrographs Are Taken. Iron Age, vol. 102, no. 6, Aug. 8, 1918, pp. 323-325, 10 figs. Apparatus for recording the gradual changes in a metal's structure when subjected to repeated bending stresses; possible applications.

Permeability

Determination of Permeability of Balloon Fabrics, J. D. Edwards. Aviation, vol. 5, no. 2, Aug. 15, 1918, pp. 103-106, 1 fig. Various methods for determining permeability to hydrogen; detailed description of method used at Bureau of Standards; discussion of phenomena of passage of gases through rubber by solution; data showing effect upon apparent permeability at different experimental conditions such as temperature, pressure, humidity of the gas, durations of test, etc.

Railroad Testing Laboratory

New Testing Laboratory, Southern Railway, Alexandria, Va. Ry. Rev., vol. 63, no. 5, Aug. 3, 1918, pp. 151-152, 3 figs. Brief description of laboratory and its equipment.

Refractories, Testing

Crushing Strength of Magnesia-Silica Mixtures at High Temperatures, O. L. Kowalke and O. A. Hougen. Iron & Steel Inst. of Canada, vol. 1, no. 7, Aug. 1918, pp. 300-304, 11 figs. Description of apparatus used; results of physical tests and microscopic examination.

Resonance Measurements

Resonance Measurements in Radio-Telegraphy with the Oscillating Audion, L. W. Austin. Jl. of Wash. Academy of Sci., vol. 8, no. 14, Aug. 19, 1918, pp. 498-500. Examples illustrating the procedure with the resonance click.

Specific Gravity Determination

Determining Specific Gravity of Viscous Tar, etc., at Different Temperatures, Renford Myhill. Gas Jl., vol. 143, no. 2882, Aug. 6, 1918, p. 254. Method used by writer.

Specific Heat

Calorimetric Determination of Curie's Point (Détermination calorimétrique du point de Curie). Jl. de Physique, vol. 7, March-April 1917, pp. 87-88. Method used by Weiss, Piccard and Carrard for measuring the mean specific heat C_m of ferromagnetic substances at temperatures between 16 deg. and 900 deg. cent.

Steam, Quality of

Testing the Quality of Steam, W. A. Taller. Mech. World, vol. 63, no. 1642, June 21, 1918, pp. 296-297, 1 fig. Effect of moisture in steam on turbine blades and on reciprocating-engine cylinders, also on lubrication; outline of two methods for determining percentage of moisture, by the throttling calorimeter and by weighing; formulæ for computations.

Steel Testing

Tests on Tie Bar from the Menai Suspension Bridge. Engineer, vol. 126, no. 3264, July 19, 1918, pp. 47-49, 3 figs. Report of the physical and metallurgical tests and the electrical resistance test.

Tanks, Measurements

Finding the Contents of a Horizontal Cylindrical Tank, Franz Szabo. Power, vol. 48, no. 8, Aug. 20, 1918, pp. 266-267, 1 fig. Gives alignment chart for the purpose.

Volumes of Cylindrical Tanks, M. W. Ward. Power, vol. 48, no 5, July 30, 1918, pp. 159-160, 1 chart. Ready method of finding contents of a horizontal cylindrical tank with contents at any depth.

Tar

See Specific Gravity Determination, above.

Vacuum Determination

Production and Measurement of High Vacua, J. E. Shrader and R. G. Sherwood. Phys. Rev., vol. 12, no. 1, July 1918, pp. 70-80, 7 figs. Attempt to modify operation of the mercury diffusion pump and the Knudsen molecular gage and tests of the two machines used in combination.

Viscosimeter

The Standardization of the Saybolt Universal Viscosimeter, W. H. Herschel. Jl. of Franklin Inst., vol. 186, no. 2, Aug. 1918, pp. 243-245. Equations between absolute viscosity and density obtained by using standard Saybolt instruments. From Technical Paper no. 112 of the Bureau of Standards.

See also Aeronautics (Instruments); Varia (Moisture Ratio).

THERMODYNAMICS

Some Recent Studies in Heat Transmission, A. J. Wood. Am. Soc. Refrig. Engrs., Jl., vol. 4, no. 5, March 1918, pp. 464-506, 8 figs. Work of thermal testing plant of Pennsylvania State College planned to include: Determination for various common materials of internal conduction (C) and combined coefficient (K) of convection and radiation as affected by velocity, humidity, difference of temperature and condition of surface; separation of this combined coefficient into its two factors, radiation and convection; deduction of laws which can be readily applied by heating and refrigerating engineers to building construction, including both simple and compound walls. Presented at annual meeting of Am. Soc. Refrig. Engrs.

TIMBER AND WOOD

Wood Grain

The Grain of Wood with Special Reference to the Direction to the Fibres, A. Koehler. Aerial Age, vol. 7, no. 22, Aug. 12, 1918, 12 figs. Influence of direction of grain on strength of timber; rules to determine direction and slope of fibers.

TRANSPORTATION

Marine Terminals

Marine Terminals for Inland River Cities Located on High Ground, H. McL. Harding. Int. Mar. Eng., vol. 23, no. 8, Aug. 1918, pp. 479-481, 7 figs. Principles governing construction of efficient river terminals; design and equipment; mechanical coördination between water and rail.

VARIA

Tractors Rough-Level Lands Before Sale to Settlers. Eng. News-Rec., vol. 81, no. 10, Sept. 5, 1918, pp. 438-439, 4 figs. Reclamation engineers get costs of putting acreage on as favorable conditions as units first entered upon.

Colored Photography

Dufay Colored Photography (El procedimiento versicolor Dufay para la fotografiá en colores). Boletin de la Sociedad de Fomento Fabril, year 35, no. 4, Apr. 1918, pp. 177-180, 6 figs. Successive operations in manufacture of films for colored photos.

Copper Statistics

The Future of Copper, W. F. Staunton. Min. & Oil Bul., vol. 4, no. 9, Aug. 1918, pp. 371-373, 3 figs. Chart showing world production for 28 years and considerations of the needs of industry.

Diamonds

Formation of Diamonds (La formation du diamant), Ch. A. Parsons. Revue Générale des Sciences, year 29, no. 11, June 15, 1918, pp. 327-333. Survey of systematic researches of the origin of diamonds and considerations on possibility of arriving at a definite conclusion in this question.

Engineering Societies

Centralized Activities of U. S. National Engineering Societies, Alfred D. Flinn. Can. Engr., vol. 35, no. 7, Aug. 15, 1918, pp. 151-154. Exposition of United States conditions to Canadian engineers.

Explosives

Science of Quarrying Rock with Explosives. Du Pont Mag., vol. 9, no. 2, Aug. 1918, pp. 4-8, 4 figs. Different ways of making blasts; suggestions and remarks.
